PREFACE TO THE THIRD EDITION.

THE present edition of the NATIONAL DISPENSATORY may be regarded as embodying the Pharmacopœias of the four chief civilized nations. Those of the United States and Germany appeared at the close of 1882, and formed the basis of our revision. The French Codex was published after our work was prepared for the press, but in time to admit of its incorporation. The British Pharmacopœia, unfortunately, has not been revised since 1867, and the references to it therefore remain unchanged.

The immense mass of new material thus brought into view has required no little labor for its presentation in a shape adapted to the wants of the practical men for whom the *Dispensatory* is designed. Absolute accuracy being of the first importance in a work of this nature, it was felt that the statements even of the Pharmacopœia were not to be blindly accepted, and a long series of investigations and tests has been carried out for the purpose of verifying or correcting them. Not a few corrections have been made, some of which the reader will find noted in their appropriate places. The formulas of the Pharmacopœia, expressed in parts by weight, have been translated into definite weights and measures, which it is hoped will facilitate their use.

In addition to the strictly official articles, a large number of extra-pharmacopœial medicines have been added to those in the previous editions, and no exertion has been spared to render the work complete in all respects.

No change has been made in the general plan of arrangement, which has been found convenient for speedy reference to the vast aggregate of matter comprehended in the volume; but a number of agents which were previously entered under individual headings have been transferred to more important articles as "Allied Drugs," while others, again, have been treated separately, as their growing importance would seem to justify. Numerous historical notes have been added. The descriptions have been extended or condensed as occasion seemed to require, and microscopical structure has been more fully described and illustrated. A large portion of the work has thus been rewritten, and the extent of the modifications and additions may be estimated from the fact that the General Index of this edition contains over thirty-seven hundred more references than that of the Second Edition. The series of illustrations has undergone a similar careful scrutiny. Many wood-cuts have been replaced by new and more satisfactory ones, and the whole number has been increased by about eighty.

Like the previous editions, this one will be found to contain the most recent views of the physiological action—as far as it explains the curative effects—of medicines; but all generalizations have been sedulously kept subordinate to the practical character of the work. The fruits of recent clinical experience have

proved to be very large, and have required for their presentation an additional space equivalent to about eighty pages of the therapeutical portion of the Second Edition. Their number and variety may be inferred from the fact that the Index of Therapeutics contains nearly sixteen hundred new references. In the previous editions very few references to authorities were furnished in this department of the work; but maturer experience has made it desirable to aid readers who wish to extend their investigations, by directing them to the more important sources of original information.

Those who use this Index should remember that its purpose is not to exhibit the *relative* values of the various medicines used in each disease. Its object is to present a suggestive list of *all* such medicines, while in the text an attempt is made to assign to each its relative as well as its positive value.

The doses of medicines are expressed in terms of the decimal system, as well as in those of apothecaries' weight, but the two are seldom exact equivalents of each other. Doses are not fixed quantities, and the numbers that represent them in either posological system should be such as are used in practice. Following the usage of German and French authorities, the doses of liquid medicines according to the metrical system are stated in terms of weight, and not of measure.

Perfection is not to be hoped for in a work consisting of infinite detail on a subject of such magnitude, but the authors feel that they may honestly claim to have shrunk from no labor in the endeavor to meet the requirements of those who will consult its pages.

PHILADELPHIA, August, 1884.

PREFACE TO THE FIRST EDITION.

IN the rapid progress of modern research few subjects have of late years received greater accessions of facts than the group of sciences connected with *materia medica* and therapeutics. The new resources thus placed at the command of the pharmacist and physician have seemed to the authors to justify an attempt to make, from the advanced stand-point of the present day, a concise but complete statement of all that is of practical importance to both professions—a digest in which that which is old and that which is new shall be so brought together as to give to the reader, within the most moderate practicable compass, all the details in pharmacology, pharmacy, and therapeutics which he is likely to need in his daily avocations. In the almost infinite accumulation of material this has required a careful and conscientious sifting to discard that which is obsolete, untrustworthy, or comparatively trivial, without impairing the practical completeness of the work. That they have wholly accomplished their object the authors do not venture to claim; but they can say that years of constant labor have been devoted to the task of producing a work to which the inquirer may refer with the certainty of finding everything which experience has stored up as worthy of confidence in the subjects embraced within its scope.

To this end there have been included all crude drugs and chemical and pharmaceutical preparations officinal in the Pharmacopœias of the United States and Great Britain, together with the more important medicines of the French Codex and German Pharmacopœia which are to some extent prescribed here or which may serve for comparison with similar articles in the English and American standards. Besides these, a large number of drugs which are not recognized by any pharmacopœia are often kept in the shops because they are prescribed by physicians or used in domestic practice. Some of these give promise of future importance, and in making a selection among this class of remedies it was deemed best not to err on the side of exclusiveness. Not only have many of them been admitted as separate articles, but a large number have found place as *allied drugs* under the heading of more important substances. To these allied drugs reference can readily be made by means of the Index.

The alphabetical order of arrangement has been adopted throughout, as being on the whole the most convenient for reference. In this the non-official medicines have been included with the officinal, the latter being distinguished by an affix showing the pharmacopœia to which they have been admitted. The title of each article is followed by a full synonymy, English, French, and German, together with Latin appellatives and popular names, such as are occasionally used in prescriptions and standard works or through which articles may be recognized. As

all substances thus have their appropriate place in the body of the work, but little is left for the Appendix, in which may be found the leading reagents, tables of weights and measures, comparisons of the scales of different hydrometers, alcoholometers, and thermometers, etc.

In the treatment of the separate articles detailed botanical descriptions have generally been omitted as being of no practical value, but plants yielding drugs have been briefly characterized as to their general aspect and habitat, while fuller descriptions have been given of those which are native or naturalized or which seemed to require it from the nature of their product. The treatment which drugs undergo before they reach the hands of the pharmacist also receives attention, because the physical appearance and chemical composition are sometimes influenced thereby. Especial care has been bestowed upon both the external and the structural characteristics of drugs, so that they may be readily identified and distinguished from those which resemble them, and in aid of this object a limited number of illustrations has been introduced, representing their outward forms as well as their histological appearances revealed by the microscope. Their proximate constituents, when of practical interest, have received special attention, and the effort has been made to decide between the conflicting statements of which these have been the subject. Chemical formulas have been expressed in the new notation, together with the molecular weights of the principal chemicals. Whenever products can be advantageously prepared by the pharmacist, one or more processes have been given and explained as fully as seemed necessary. Attention has been drawn to adulterations and impurities, and the means for detecting them have been pointed out. The officinal processes for pharmaceutical preparations have in most instances been detailed in the language of the Pharmacopœia, followed, when requisite, by explanatory and critical remarks and practical observations for the guidance of the operator.

With regard to Pharmacodynamics, there is presented, for the first time in a Dispensatory, a succinct account of the physiological action of medicines. The results of experiments are stated as clearly as possible, and occasionally in the theoretical language of the day; but, as a rule, terms have been employed whose meaning is not likely to become obsolete or unintelligible. Whenever it seemed possible an attempt to apply the results of physiological experiments to therapeutical uses has been made; for although the two fields of inquiry may not be so organically connected as to render the former a guide to the latter, it is nevertheless true that a scientific explanation of the curative powers of medicines must be sought in the results of their experimental operation upon the animal functions.

In treating of Therapeutics the most trustworthy results of clinical experience are concisely set forth, without discussing the grounds on which they rest. This method has proved laborious, and has often required a prolonged judicial examination to arrive at a conclusion expressed in a few lines. Its object has been to spare the reader the labor of a personal investigation, which could only be made with facilities which comparatively few possess.

Another feature, novel in a Dispensatory, is the Therapeutical Index. Care has been taken to render it as complete as possible, in order that the inquirer may be enabled to learn by its means all of the more important medicines that have been employed in the treatment of each disease. Such an index thus becomes to some extent a therapeutical classification of medicines, and it is believed must

greatly enhance by its suggestiveness the working value of the book to the practitioner.

On mature consideration it was deemed best not to encumber the text with references to authorities, save in exceptional cases, such as those in which the opinions cited must be estimated by the credit attaching to their originators. Frequently, in the pharmaceutical portion, the year is stated in which the observation or discovery was made, which may serve as a guide to those desiring to undertake further research. For the more recent investigations, the Reports on the Progress of Pharmacy contained in the annual *Proceedings of the American Pharmaceutical Association* and the *Year-Book of Pharmacy* of the British Pharmaceutical Conference afford sufficient opportunities for ascertaining the original sources and consulting abstracts of original papers.

The statistics of importation have been taken from the Reports of the New York Chamber of Commerce, for which they were prepared by Mr. D. C. Robbins, based upon the Tables of the Bureau of Statistics at Washington.

PHILADELPHIA, February, 1879.

THE NATIONAL DISPENSATORY.

ABRUS.—ABRUS.

Indian Liquorice, Wild Liquorice, E.; Liane réglisse, Réglisse d'Amérique, Fr.; Indisches Süsshholz, G.

The root and seeds of *Abrus precatorius*, Linné. Bentley and Trimen, *Medicinal Plants*, 77.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—This is a twining shrub, attaining a height of 10 or 15 feet (3 or 4.5 M.). It is indigenous to India, where it is known as *gunja*, *goontch*, or *gurgonje*, and now grows wild in all tropical countries. The leaves are 4 to 6 inches (10–15 Cm.) long, short-petiolate, abruptly pinnate, and have from 20 to 30 linear or oblong, obtuse, entire, smooth, and pale-green leaflets. The flowers are rose-colored, short-stalked, and clustered in one-sided, long-stalked racemes. The legumes are about $1\frac{1}{2}$ inch (3 Cm.) long, oblong-rhomboidal, short-beaked, and contain from 4 to 6 seeds.

Description.—RADIX ABRU. The root is long, and is seen in commerce in more or less twisted pieces, varying in length, and about $\frac{1}{4}$ to 1 inch (6 to 25 Mm.) thick. It has a thin, pale reddish-brown bark, containing near the middle layer a circular zone of sclerenchyma-cells, and in the inner layer strong bast-fibres, which are scattered without regularity through the liber parenchyma. The wood is yellowish, porous, breaks with a short fibrous fracture, and is composed of circles of wood-fibres containing rather large ducts and alternating with circles of parenchyma, the whole radially traversed by medullary rays, some of which are narrow, others much broader. The root has a slight not agreeable odor and a bitterish, mucilaginous taste, with a sweet after-taste resembling that of liquorice-root.

SEMEN ABRU; Prayer-beads, Jumble-beads, Crab's eyes, *E.*; Pois d'Amérique, *Fr.*; Paternoster-Erbsen, *G.* The seeds are globular-ovate, about $\frac{1}{8}$ inch (5 Mm.) long, scarlet-red, glossy, and have a black spot surrounding the hilum; the testa is hard, and encloses a whitish fleshy embryo consisting of plano-convex cotyledons and an accumbent radicle. The seeds are inodorous and have a slight bean-like taste. They have been introduced under their Brazilian name, *jequiriti* or *guequiri*.

Composition.—Berzelius ascertained that the leaves and branches contain a principle closely resembling glycyrrhizin. The same principle is also present in the root, which in addition contains sugar; but nothing is known of the remaining constituents. Prof. Warden (1882), by treating the seeds with boiling alcohol, obtained white crystalline *abric acid*, which is slightly soluble in cold water, and appears to have the formula $C_{12}H_{24}N_3O$. The seeds also contain fixed oil, and an alkaloid has been isolated by Rigaud and Dusart (1883); but neither of these compounds seems to be the irritating principle.

Medical Action and Uses.—This plant is said to have been used for centuries in Brazil as a popular remedy for granular lids and pannus. In 1862 attention was called to it in Europe, but it was soon forgotten, and it was not until 1882 that renewed interest was awakened in it by the reports of De Wecker. An infusion, of the strength of one to twenty, applied to the eye of a rabbit produced violent inflammation of the organ, with œdema and false membrane, ulceration of the cornea, swelling of the parotid and submaxillary glands, and finally internal suppuration of the eyes and maxillary glands, and gangrene of the eyelids. It is said that the drug is much abused in Brazil, and that "one often sees violent inflammation of the lids which extends to the face, neck, and upper part of the thorax, the submaxillary glands often taking on an intense inflammation which ends in suppuration" (*Med. News*, xlii. 412). In experiments upon animals

Carnil and Berlioz determined that when injected under the skin or into the blood it produces in the former situation abscess or gangrene, and in the latter virulent tonical phenomena, with an enormous generation of bacilli in the blood and lymph (*Archives gén.*, Nov. 1883, p. 623). As to its mode of action, Sattler comes to the conclusion that "an apparently widely distributed and apparently harmless bacillus, when its spores come in contact with an infusion of jequirity, acquires a new physiological property—viz. of vegetating on the living conjunctiva, and producing a ferment there which produces the inflammation known as jequirity ophthalmia" (*Edenb. Med. Jour.*, xxix. 378).

The use of abrus is limited at present to those obstinate cases of *granular ophthalmia*, *trachoma*, and *pannus* which are notoriously rebellious to treatment, and which some surgeons have not scrupled to attempt to cure by the application of gonorrhœal pus. Its action is altogether substitutive, the removal of an existing inflammation by the action of a stronger but temporary one. De Wecker described the effects of its application thus: The infusion is applied several times a day until its action begins to be felt. Within a few hours after the first use of the lotion the conjunctiva becomes strongly irritated, and on the following day severely inflamed; the eyes cannot be opened, the lids are œdematous, and a watery liquid escapes from between them. This period of irritation lasts for about three days, and is attended with fever, pain, and sleeplessness. On the third day suppuration begins, and for five days continues copiously, and then gradually declines until about the fifteenth day, when the patient finds himself free from both inflammation and granulation, while the cloudiness of the cornea subsides (*Centrabl. f. Therap.*, i. 200). In this description no allusion is made to the striking peculiarity mentioned by most other reporters, the formation of a false membrane upon the conjunctiva; which, indeed, was originally described by De Wecker and by various other observers as a yellowish-white membrane adhering firmly to the upper, but less so to the lower, lids (Grœning, *Med. Record*, xxiii. 288; Brown, *Med. News*, xlii. 412). De Wecker also asserted that the cornea is not at all endangered by the artificial inflammation (*loc. sup. cit.*), a statement also made by Peck (*Med. Record*, xxiv. 30); but Sattler makes the very opposite declaration, saying that not only may the application cause existing ulcers to spread, but that it may also create new ones (*Centrabl. f. Therap.*, i. 335); and Standish admits that the result is not unusual (*Boston Med. & Surg. Jour.*, June, 1883, p. 609).

It is perhaps natural that under the influence of current medical doctrines some ophthalmologists have insisted that the curative action of abrus is much more than that of a substitutive inflammation such as the various stimulants produce which are used to cure granular lids, and that "jequirity ophthalmia arises from pathogenic micro-organisms," which Sattler professes to have differentiated, declaring that the removal of these bodies from the solution renders it inert, while they, on the other hand, preserve the power of generating the characteristic inflammation. Haranger also claims to have "found in an infusion of jequirity, as in the pus of gonorrhœa, micrococci, corpuscles, and granules" (*Bull. de therap.*, civ. 42). These conclusions appear to have been fully sustained by the experiments of Carnil and Berlioz, who declare that "the bacteriæ of jequirity are its only active principle" (*Archives gén.*, Nov. 1883, p. 618).

The mode of using this remedy is described by De Wecker as follows: "Powder 32 jequirity beans, and macerate them for 24 hours in 500 Gm. (a pint) of cold water; then add an equal quantity of hot water, and filter when cool. The patient should bathe the eyes with this infusion several times a day until inflammation sets in." Others advise the liquid to be applied with a camel's-hair pencil. Sattler directs that the envelope of from 10 or 12 seeds (Gm. 1) should be removed with hot water before the infusion is made; the seeds should then be powdered and 200 Cem. (℥vi) of hot water added. This infusion should, after standing for 24 hours, be filtered. Its strength is reckoned as $\frac{1}{2}$ per cent. At the Wills' Eye Hospital, Philadelphia, an infusion is used containing 9 grains to the ounce. Its decomposition is prevented by the addition of boric acid in the proportion of 4 grains of the acid to each ounce of the infusion.

ABSINTHIUM, U. S.—ABSINTHIUM.

Herba s. Summitates absinthii, P. G.; Wormwood, E.; *Absinthe commune*, *Grande absinthe*, *Armoise amère*, Fr.; *Wermuth*, *Alsei*, G.

The tops and leaves of *Artemisia Absinthium*. Linné; s. *Absinthium vulgare*, Lamarck; Woodville, *Med. Bot.*, 22; Bentley and Trimen, *Med. Plants*, 156.

Nat. Ord.—Compositæ, Senecionideæ.

Description.—This perennial plant is indigenous to hilly and mountainous regions of Northern Africa, of the greater portion of Europe, and of the northern part of Asia; it is frequently cultivated for medicinal purposes both in Europe and in this country, where it has become naturalized in some localities, and grows wild in waste places and along roadsides. The root produces several stems, which are 3 to 4 feet high (1 to 1.2 M.), woody at the base, nearly round, somewhat furrowed, and branching above. The radical leaves attain a length of 6 to 8 inches (15 to 20 Cm.); the stem-leaves are 1 to 3 inches (25 to 75 Mm.) long, petiolate, the upper ones sessile; their outline is roundish-triangular; they are twice or thrice pinnatifid, the segments lanceolate, the terminal one spatulate. The bracts are merely three-cleft or simple and lanceolate. The very numerous nodding heads of yellow flowers are in paniculate racemes, hemispherical in shape, with the involucre imbricate; the receptacle small and hairy, the marginal florets pistillate, and not ligulate, the numerous disk-florets perfect and five-toothed, and the ovary obovoid and crowned with a disk, but destitute of pappus. The entire plant, with the exception of the stouter portions of the stem, has a hoary appearance from the numerous appressed white silky hairs, leaving merely the upper surface of the leaves of a dark-green color.

Wormwood should be gathered while flowering, during July or August, the coarse stems being rejected. On careful drying the fresh herb loses from 75 to 80 per cent. of its weight. The wild-grown herb has a strong aromatic not very agreeable odor, and a persistent and intensely bitter taste; in cultivation the bitter taste is somewhat decreased.

Constituents.—The odor of wormwood is due to a limpid volatile oil, of which from .4 to 1.5 per cent. is obtained from the dry herb. According to Zeller, wormwood grown in a warm climate yields less volatile oil, and cultivation appears to decrease it. Its color varies between dark-green and yellowish-brown, but by careful rectification it may be obtained colorless. On exposure to light and air it acquires a dark-brown color and a somewhat viscid consistence. Its specific gravity varies between .90 and .973; it dissolves in 1 part of 85 per cent., and in all proportions of absolute, alcohol; has a rotating power to the right in the polariscope, and possesses the pungent aromatic odor and taste of the herb. It consists mainly of *absinthol*, the composition of which is $C_{10}H_{16}O$, which boils at $200^{\circ} C.$ ($392^{\circ} F.$), and splits with zinc chloride into water and cymene, $C_{10}H_{14}$; it contains also 2 per cent. of terpenes boiling at 150° and above $120^{\circ} C.$, and a few per cent. of blue oils boiling at $300^{\circ} C.$ and upward (C. R. A. Wright, 1874). The volatile oil is the chief constituent of the liquor, which is largely consumed in Western Europe under the name of *absinthe*, and which is prepared either by distilling wormwood, melissa, anise, and other aromatics with whiskey, or by dissolving in the latter the corresponding volatile oils.

The intensely bitter taste resides in *absinthin*, which may be obtained from the hot infusion of the herb by precipitating it with tannin, washing the precipitate, and decomposing it by oxide of lead; the dry residue is exhausted with alcohol, the solution treated with animal charcoal, evaporated, and dissolved in ether. On evaporating the ether, it is left behind as a colorless mass yielding a white powder. It is fusible; slightly soluble in hot water, freely in alcohol and ether. Its solution in potassa is brown-red; the ammoniacal solution, treated with hydrochloric acid in excess, is rose-red. Composition: $C_{40}H_{58}O_9$, Kromayer ($C_{40}H_{56}O_{12}$, Luck). It was first obtained in 1828 by Caventou, in a still impure condition; Mein prepared it in white prisms (1834). Wormwood contains also some tannin (green with iron salts), resin, starch, albumen, potassium nitrate and other salts, succinic (Braconnot's absinthic acid, 1815), malic, and acetic acids.

Other Medicinal Species of Artemisia.—A. *POSTICA*, Linné: Roman wormwood, *E.*; Petite absinthe, *Fr.*; Römischer Beifuss, *G.* Indigenous to Southern Europe and Central Asia. Hoary tomentose, leaves decoumpound pinnatifid, segments narrow linear; smaller than the preceding; odor strong, more pleasant; taste pungent, aromatic, and bitter; less esteemed than wormwood.

A. *ABROTANUM*, Linné: Southernwood, Old Man, *E.*; Aunone des jardins, *Fr.*; Eberraute, *G.* Western Asia and Southern Europe; cultivated in U. S. Minutely hairy, segments of the pinnatifid leaves capillaceous; odor lemon-like; taste aromatic and bitter.

A. *VULGARIS*, Linné: Mugwort, *E.*; Couronne de Saint-Jean, Armoise commune, *Fr.*; Beifuss, *G.* Northern Africa, Europe, and Siberia; cultivated and spontaneous in U. S. Stem often purplish; leaves subsessile, green above, white tomentose beneath, pinnatifid, segments linear lanceolate, often incised; odor aromatic, agreeable; taste aromatic, bitterish, and somewhat acid. The root, *Radix artemisiae*, is also medicinally employed in Europe. It is about 8 inches (20 Cm.) long, nearly an inch (25 Mm.) thick, woody and beset with numerous thin and tough radicles, which are the parts used: they are 2 to 4 inches (5 to 10 Cm.) long, and about $\frac{1}{2}$ of an inch (2 Mm.) thick, are light brown, internally whitish, and have an angular wood and a thick

bark, with a thin bast-layer, and, outside thereof, with 5 or 6 groups of resin-cells. The root has a slight not very pleasant odor, a sweetish and slightly acrid taste, and contains, according to Hummel and Jänicke (1826), Bretz and Eliason (1826), and Hergt (1830), a little butyraceous volatile oil, acrid resin, tannin, etc.

A. DRACUNCULUS, *Liné*; Tarragon, *E.*; Estragon, *Fr.*; Dragenbeifuss, Kaisersalat, *G.* Siberia, Tartary, Southern Europe; cultivated. Plant green and glabrous; radical leaves trifid; stem-leaves narrow lanceolate, entire; odor anise-like; taste aromatic, bitterish. The volatile oil is identical in composition with oil of anise.

A. LUDOVICIANA, *Nuttall*; Western Mugwort. It grows from Michigan to Oregon and southward, is 3 to 5 feet (1–1.5 M.) high, white woolly, with lanceolate, deeply cut, serrate, or entire leaves and numerous small flower-heads. It has a bitter taste, and a slight odor like that of wormwood. The fruit of this species, and of *A. dracunculoides*, *Pursh*, is used as food by the Indians. The last-named plant extends from Western Illinois to Oregon and southward to Arizona; recently it has also appeared in Arkansas. It has linear entire smooth leaves, of which the lower ones are occasionally three-cleft, and very numerous small mostly pedicelled heads in compound leafy panicles. The odor is wormwood-like, not very strong, and the taste somewhat bitter.

A. FILIFOLIA, *Torrey*, growing west of the Rocky Mountains, and known there as *Southern-wood*, has filiform, revolute, sometimes three-cleft, whitish tomentose leaves, and small about four-flowered heads in leafy panicles, and is more aromatic than the preceding.

A. TRIDENTATA, *Nuttall*, is the *sagebrush* of Western North America, growing from Sonora to Nevada and Oregon and eastward to the Rocky Mountains. It is a shrub 5 or 6 feet ($1\frac{1}{2}$ to 2 M.) high, with crowded caescent, cuneate, and truncate, mostly bluntly three-toothed leaves and obovoid or oblong flower-heads, which are about $\frac{1}{8}$ inch (4 Mm.) long, are about five-flowered, and spicately clustered in narrow compound panicles. The plant contains a pungent volatile oil, and is used by the Indians in the form of infusion for headaches, colds, and for worms.

A. ARBUSCULA, *Nutt.*, and *A. TRIFIDA*, *Nutt.*, are the dwarf sagebrushes of the same localities, and have similar properties.

A. ABYSSINICA, *Olivier*, is known in Abyssinia as *tshuking* and *zerechit*. The inflorescence, which is employed, forms corymbose racemes with small globular heads, having a woolly involucre, whitish florets, an aromatic odor, somewhat resembling chamomile and tansy, and an aromatic bitterish taste. Dragendorff (1878) found in it 1.7 per cent. volatile oil, 2.8 tannin, and a trace of bitter principle.

Pharmaceutical Preparations.—EXTRACTUM ABSINTHII of the German Pharmacopœia is prepared with diluted alcohol; that of the French Codex with boiling distilled water.

TINCTURA ABSINTHII. *P. G.* 1 part of wormwood is digested with 5 parts of alcohol, sp. gr. 892, and expressed.

Physiological Action.—*On Animals*: Given to dogs and rabbits, the essential oil and the extract of absinth produce a species of intoxication, with spasms and insensibility, and, in large doses, epileptiform convulsions. During this state the pupil is dilated and the interior of the eye intensely congested, as are also the membranes of the brain. *On Man*: Absinth in medicinal doses acts as a stimulant tonic, but excessive doses occasion disturbance of the cerebral functions, and convulsions, which, according to Lancereaux, are clonic and not tonic, hysteroidal and not epileptiform; but their form varies with the dose administered. The habitual use of alcohol flavored with absinth gives rise to a peculiar chronic intoxication, in which degradation of the mental and physical powers and a tendency to convulsive epileptiform affections are conspicuous. The sensibility of the skin, and especially over the lower part of the abdomen, is said to be morbidly increased. Chronic intoxication by alcohol containing absinth is said to be characterized by alternations of excitement and depression, and by more frequent and frightful hallucinations than chronic alcoholism. The male victims of the habit soon lose their genital vigor, and the females cease to menstruate prematurely. Nearly all die of phthisis (Gautier, *Bull. de théér.*, ciii. 95). Absinthin produces similar phenomena. It is alleged that the convulsive attacks it causes differ from those of epilepsy in not including stertor, coma, or lividity of the face.

Medical Uses.—Wormwood may be advantageously employed in *atonic* and especially *flatulent dyspepsia*, and in various conditions of the system in which local disorders are maintained by general debility of the functions, and particularly by that of the digestive apparatus. In this manner partly, and partly also as a direct anthelmintic, it sometimes is used successfully to remove *intestinal worms*. Externally, a decoction of wormwood may be applied as a dressing to unhealthy and indolent *ulcers*. The *dose* of wormwood in substance is from 20 to 40 grains (Gm. 1.30–2.60). An *infusion* made with an ounce (Gm. 32) of wormwood in a pint of water (Gm. 500) may be given in doses of 1 or 2 fluidounces (Gm. 32–64).

A. vulgaris was at one time held in high repute as a remedy for *epilepsy*, and especially

for those cases of it which occur in persons of feeble constitution and of a highly nervous temperament—more especially in young females with disordered menstruation. It was prescribed in hot infusion, so as to provoke diaphoresis, not only for epilepsy, but also for the cure of *amenorrhœa*.

Prof. Maisch has included the following statements in a "Note on Some American Species of *Artemisia*" (*Amer. Jour. of Phar.*, lii. 69): The infusion of *A. ludoviciana* was recommended as a hair tonic and febrifuge. The same plant was used by the Pahlutes to assist childbirth and to stop hæmorrhage from the nose. *A. dracunculoides* is said to produce irritation when bruised, and the tea of it to be diaphoretic. *A. filifolia*, according to Dr. Palmer, is used in decoction by the Indians against swellings and bruises, and a very penetrating volatile oil obtained by distillation is useful in liniments. According to the same authority, a strong tea made from the sage-plant of the Rocky Mountains, which includes several species of *Artemisia*, is given for headache, colds, and worms, and a pungent volatile oil may be obtained from it.

ABSTRACTA.—ABSTRACTS.

Abstrais, Saccharures, Fr.; Abstrakte, G.

These are a new class of preparations which have been proposed by Professor Remington, and are intended to replace certain commercial so-called powdered extracts made by processes which have not been made public. The abstracts are alcoholic extracts diluted with sugar of milk, so that the weight of one part of the finished product represents two parts of the drug. This definite relation of weight is of advantage in adjusting the dose, which is one-half that of the drug itself. But since they are in no case directed to be made from standardized drugs, the variation of the medicinally active principles must be in proportion to the variation existing naturally in the crude drugs; even in the case of jalap only the lowest limit of alcoholic resin (12 per cent.) has been fixed for the drug. A valuable paper on this class of preparations was contributed by C. S. Hallberg to the *Proceedings* of the American Pharmaceutical Association, 1881, p. 424.

Similar preparations were recommended by Béral (1830) under the name of *saccharures*, and have been employed to a limited extent in France. They are prepared by intimately mixing 60 Gm. of tincture with 500 Gm. of granulated white sugar, and drying the mixture by exposure to the air or at a moderate heat; the tinctures being made in the proportion of 1 : 5, these saccharures represent 1 per cent. of their weight of the drug. Réveil subsequently proposed their preparation from a definite quantity of the alcoholic extract instead of from the drug. Danneccy recommended saccharures made in the same manner with aqueous extracts, as convenient for the extemporaneous preparation of *tisanes*. (See INFUSIONS.)

In some parts of Europe it has long been customary, for convenience in dispensing, to mix the narcotic extracts with milk-sugar, to exsiccate the mixture, and reduce it to powder. This practice was legalized by the Prussian Pharmacopœia in 1846, and has been retained in the Austrian Pharmacopœia, which directs such *extracta narcotica siccata* to represent one-half their weight of the extracts. Aside from the manipulation, these preparations differ from the abstracts in being exactly one-half the strength of the official extracts, instead of double the strength of the drugs.

Preparation.—The pharmacopœial formulas for the different abstracts are alike, with the exception of a few mostly unimportant differences, which are pointed out below.

The menstruum directed is in all cases, except for aconite and nux vomica, a stronger alcohol than is required for the corresponding fluid extracts, and the latter cannot therefore be employed for preparing identical abstracts. The general formula is as follows:

Drug in powder No. 60 (conium-fruit and jalap in powder, No. 40) 200 parts (4 oz. av.); Sugar of Milk recently dried and in fine powder, alcohol (for ignatia and nux vomica alcohol and water), each a sufficient quantity; to make 100 parts (2 oz. av.). Moisten the powder with 80 parts (700 grains or 15 fluidrachms) of Alcohol (for modifications for aconite, conium, jalap, ignatia, and nux vomica, see table), and pack firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, until the powder is exhausted. Reserve the first 170 parts (1488 grains, or about 3½ fluidounces) of the

percolate; evaporate the remainder to 30 parts (263 grains, or about 4 fluidrachms) at a temperature not exceeding 50° C. (122° F.), and mix with the reserved portion. Place the mixture in an evaporating-dish, and, having added 50 parts (1 oz. av.) of sugar of milk, cover it with a piece of thin muslin gauze, and set aside in a warm place, where the temperature will not rise above 50° C. (122° F.), until the mixture is dry. Lastly, having added enough sugar of milk to make the mixture weigh 100 parts (2 oz. av.), reduce it to a fine, uniform powder. Preserve the powder in a well-stoppered bottle.—*U. S.*

The following table exhibits the modifications of each process:

Drug, 200 parts (4 oz. av.).	Powder.	Menstruum directed.	Menstruum for moistening powder.			Percolate.						Add milk-sugar.		Final product.

* Containing 2 parts (or 17½ grains) of tartaric acid.——† Containing 6 parts (52½ grains = 48 minims) of hydrochloric acid.

Properties.—Abstracts prepared according to the Pharmacopœia form light-colored powders, having the shade indicated in the above table and retaining the odor of the drug in a marked degree. On exposure to the air they attract some moisture and are apt to cake somewhat, those of hyoscyamus and valerian more than the others; abstracts should therefore be kept in well-corked vials and in a dry place.

ABSTRACTUM ACONITI RADICIS, *U. S.*—ABSTRACT OF ACONITE-ROOT.

Abstrait d'aconit, Fr.; Akonitabstrakt, G.

Preparation.—Aconite-Root in No. 60 powder 200 parts (4 oz. av.); Tartaric Acid 2 parts (17½ grs.); Sugar of Milk recently dried and in fine powder, and Alcohol, each a sufficient quantity. Dissolve the tartaric acid in 80 parts (700 grains, or 15 fluidrachms) of alcohol; moisten the powder with this solution, and pack firmly in a cylindrical glass percolator. Then proceed according to the general directions given on page 5, using alcohol for percolation. The finished abstract should weigh 100 parts (2 oz. av.).—*U. S.*

Although tartaric acid is used in the preparation of aconitine in an unaltered condition, in accordance with the suggestion of C. R. A. Wright (see ACONITIA), it is doubtful whether it serves a really useful purpose in this case (see also EXTRACTUM ACONITI). 30½ fluidrachms of the present official fluid extract of aconite-root, if evaporated with a sufficient quantity of milk-sugar, will yield 2 oz. av. of abstract identical with the above.

Dose.—One-half to 1 grain (Gm. 0.03–0.06).

ABSTRACTUM BELLADONNÆ, *U. S.*—ABSTRACT OF BELLADONNA.

Abstrait de belladone, Fr.; Belladonnaabstrakt, G.

Preparation.—Belladonna-Root in No. 60 powder 200 parts (4 oz. av.); Sugar of Milk recently dried and in fine powder, Alcohol, each a sufficient quantity. Proceed according to the general directions given on page 5, using alcohol for moistening and percolation. The finished abstract should weigh 100 parts (2 oz. av.).—*U. S.*

Dose.—Half a grain, as a commencing dose (Gm. 0.03).

ABSTRACTUM CONII, U. S.—ABSTRACT OF CONIUM.*Abstrait de ciguë, Fr.; Schierlingabstrakt, G.*

Preparation.—Conium-fruit in No. 40 powder 200 parts (4 oz. av.); diluted Hydrochloric Acid 6 parts (52½ grains, or 48 minims); Sugar of Milk recently dried and in fine powder, Alcohol, each a sufficient quantity. Mix the hydrochloric acid with 80 parts (700 grains, or 15 fluidrachms) of alcohol; moisten the powder with this mixture, and pack firmly in a cylindrical *glass* percolator. Then proceed according to the general directions on page 5, using alcohol for percolation. The finished abstract should weigh 100 parts (2 oz. av.).—*U. S.*

The addition of hydrochloric acid is made to prevent the volatilization of the alkaloid conine during the concentration of the tincture.

Dose.—The dose of conium itself is quite variable, and hence the dose of its abstract must be uncertain. At first not more than 1 or 2 grains (Gm. 0.06–0.12) should be given at a time.

ABSTRACTUM DIGITALIS, U. S.—ABSTRACT OF DIGITALIS.*Abstrait de digitale, Fr.; Digitalisabstrakt, G.*

Preparation.—Digitalis *recently dried* and in No. 60 powder 200 parts (4 oz. av.); Sugar of Milk recently dried and in fine powder, Alcohol, each a sufficient quantity. Proceed according to the general directions given on page 5, using alcohol for moistening and percolating. The finished abstract should weigh 100 parts (2 oz. av.).—*U. S.*

Dose.—From half a grain to 1 grain (Gm. 0.03–0.06).

ABSTRACTUM HYOSCYAMI, U. S.—ABSTRACT OF HYOSCYAMUS.*Abstrait de jusquiame, Fr.; Hyoscyamusabstrakt, G.*

Preparation.—Hyoscyamus *recently dried* and in No. 60 powder 200 parts (4 oz. av.); Sugar of Milk recently dried and in fine powder, Alcohol, each a sufficient quantity. Proceed according to the general directions on page 5, using alcohol for moistening and percolating. The finished abstract should weigh 100 parts (2 oz. av.).—*U. S.*

Dose.—From 3 to 6 grains (Gm. 0.20–0.40).

ABSTRACTUM IGNATIÆ, U. S.—ABSTRACT OF IGNATIA.*Abstrait de fève de Saint-Ignace, Fr.; Ignazbohnen-Abstrakt, G.*

Preparation.—Ignatia in No. 60 powder 200 parts (4 oz. av.); Sugar of Milk recently dried and in fine powder, Alcohol, Water, each a sufficient quantity. Mix 8 parts of alcohol with 1 part of water (or in the proportion of 9½ fluidounces of alcohol to 1 fluidounce of water); moisten the ignatia with 100 parts (2 oz. av., or 18 fluidrachms) of the mixture, and then proceed according to the general directions on page 5, using the same mixture for percolation. The finished abstract should weigh 100 parts (2 oz. av.).—*U. S.*

Ignatia is difficult to powder; the object is best accomplished on a small scale by somewhat crushing the seeds, and then heating them with a little water until they become soft enough to be bruised, while still warm, into a pulpy mass, with which a little alcohol is incorporated. It may then be dried and powdered for displacement.

Dose.—Half a grain (Gm. 0.03), and gradually increased.

ABSTRACTUM JALAPÆ, U. S.—ABSTRACT OF JALAP.*Abstrait de jalap, Fr.; Jalapenabstrakt, G.*

Preparation.—Jalap in No. 40 powder 200 parts (4 oz. av.); Sugar of Milk recently dried and in fine powder, Alcohol, each a sufficient quantity. Moisten the jalap with 100 parts (2 oz. av., or 18½ fluidrachms) of alcohol, and proceed according to the general directions on page 5. The finished abstract should weigh 100 parts (2 oz. av.).—*U. S.*

This abstract is of about the same medicinal activity as the extract prepared by exhausting jalap successively with alcohol and water, and is free from the inert matter contained in the latter. The alcoholic extract amounts to from 14 to 22 per cent. of the weight of jalap, of which a portion is soluble in water; this aqueous extract of the alco-

holic extract possessing mild diuretic and laxative properties, the officinal resin of jalap should not be used for the preparation of the abstract. The dry alcoholic extract of jalap triturated with milk-sugar yields an apparently uniform powder, the ingredients of which will separate to some extent on keeping; prepared according to the Pharmacopœia process, the abstract retains its uniform composition apparently for an indefinite period.

DOSE.—From 8 to 12 grains (Gm. 0.50–0.80).

ABSTRACTUM NUCIS VOMICÆ, U. S.—ABSTRACT OF NUX VOMICA.

Abstrait de noix vomique, Fr.; Brechnussabstrakt, G.

Preparation.—Nux Vomica in No. 40 powder 200 parts (4 oz. av.); Sugar of Milk recently dried and in fine powder, Alcohol, Water, each a sufficient quantity. Mix 8 parts of alcohol with 1 part of water (or in the proportion of 9½ fluidounces of alcohol to 1 fluidounce of water); moisten the nux vomica with 100 parts (2 oz. av., or 18 fluidrachms) of the mixture, and proceed according to the general directions on page 5, using the same mixture for percolation. The finished abstract should weigh 100 parts (2 oz. av.).—U. S.

Nux vomica may be powdered for displacement in the same manner as ignatia-seeds, or the unbroken nux vomica may be exposed to steam until thoroughly softened, when, while still warm, it is crushed, dried, and powdered.

DOSE.—Half a grain (Gm. 0.03), and gradually increased.

ABSTRACTUM PODOPHYLLI, U. S.—ABSTRACT OF PODOPHYLLUM.

Abstrait de podophyllum, Fr.; Podophyllum-Abstrakt, G.

Preparation.—Podophyllum in No. 60 powder 200 parts (4 oz. av.); Sugar of Milk recently dried and in fine powder, Alcohol, each a sufficient quantity. Proceed according to the general directions on page 5, using alcohol for moistening and percolation. The finished abstract should weigh 100 parts (2 oz. av.).—U. S.

DOSE.—5 to 10 grains (Gm. 0.30–0.60).

ABSTRACTUM SENEGÆ, U. S.—ABSTRACT OF SENEGA.

Abstrait de sénéga, Fr.; Senega-Abstrakt, G.

Preparation.—Senega in No. 60 powder 200 parts (4 oz. av.); Sugar of Milk recently dried and in fine powder, Alcohol, each a sufficient quantity. Proceed according to the general directions on page 5, using alcohol for moistening and percolation. The finished abstract should weigh 100 parts (2 oz. av.).—U. S.

DOSE.—5 to 10 grains (Gm. 0.30–0.60).

ABSTRACTUM VALERIANÆ, U. S.—ABSTRACT OF VALERIAN.

Abstrait de valériane, Fr.; Baldrianabstrakt, G.

Preparation.—Valerian in No. 60 powder 200 parts (4 oz. av.); Sugar of Milk recently dried and in fine powder, Alcohol, each a sufficient quantity. Proceed according to the general directions on page 5, using alcohol for moistening and percolation. The finished abstract should weigh 100 parts (2 oz. av.).—U. S.

DOSE.—5 to 15 grains (Gm. 0.30–1).

ACACIA, U. S.; ACACIÆ GUMMI, Br.—GUM ACACIA.

Gummi arabicum, Gummi mimosæ, P. G.—Gum arabic, E.; Gomme arabique, Fr.; Arabisches Gummi, G.

A gummy exudation from Acacia Verek, *Guillemin et Perottet*, and other species of Acacia. Bentley and Trimen, *Med. Plants*, 94.

Nat. Ord.—Leguminosæ, Mimosæ.

Origin.—The gum-yielding species of Acacia are shrubs or trees with mostly abruptly bipinnate leaves, and with the stipules often transformed into thorns. The flowers are generally yellow, have numerous stamens, and are aggregated in dense elongated spikes or in globular heads.

A. Verek, *Guil. et Per.*, s. A. (Mimosa, *Lâmé*) Senegal, *Willdenow*, occurs from Kordofan,

where it is called *Hashab*, west to the river Senegal; it is a small tree attaining the height of 20 feet (about 6 M.), and yields the Kordofan and Senegal gums.

Acacia vera and *A. arabica*, *Willd.*, which Ehrenberg considered as mere varieties, are now regarded as such, and identical with *A. nilotica*, *Desfontaines*, and *Mimosa arabica*, *Rorburgh*. This middling-sized tree is indigenous and also cultivated from Egypt south to Abyssinia and west to Senegambia; also in Arabia and India. Near the Nile it is known by the name of *Sont*.

A. tortilis, *Forsk.*, a small or medium-sized tree, called *Seyal* or *Seyaleh*, grows in Arabia and Upper Egypt.

A. Ehrenbergii, *Hayne*, a shrub 10 to 12 feet (3 or 4 M.) high, called *Segah*, is found in Arabia and Upper Egypt.

Collection and Commerce.—Gum arabic is probably formed by the metamorphosis of the cell-walls of the parenchyma, or, according to Carré, of the vascular bundles in the cambium layer; some investigators, however, consider it as the product of the transformation of starch, and that this process occurs either regularly, or is increased in consequence of a diseased condition of the plant. The gum exudes spontaneously, but the discharge is often hastened by incisions. It is yielded most plentifully during the hot summer months, the trees producing it in largest quantity having a sickly appearance. The thick liquid hardens upon the bark, and finally falls to the ground, but is collected by detaching it from the tree with the aid of a wooden axe.

The best gum is collected westward of the White Nile in Kordofan, and enters commerce by being shipped down the Nile to Alexandria; it is the *Kordofan gum*, called *Hashabi* in Egypt. A gum nearly or quite as handsome in appearance, though considered inferior in quality, is collected near the Blue Nile and shipped from Sennaar, either down the Nile or by way of the port of Suakin (Savakin) on the Red Sea; it is the *Sennaar* or *Sennari gum*, which, of late years, has become quite plentiful in our commerce. The kind known in commerce as *Suakin* or *Savakin gum* is collected farther east, not far from the west coast of the Red Sea, and shipped from the port named. The gum collected in Southern Abyssinia and adjoining countries is mostly exported from Berbera, either by way of the East Indies or through some neighboring ports of Arabia to the Mediterranean. Some gum is collected in India from several species of *Acacia*, and also from *Feronia elephantum*, *Correa*, but the great bulk of the commercial *East Indian gum* is of African origin. Arabia also yields a little gum, but the *Gedda* or *Jidda gum* and the *gum Tor* or *Toric* come originally from the Somali coast of Eastern Africa.

Gum arabic, before it finally enters commerce, is usually assorted in the Mediterranean ports, the clearest and whitest quality being known as *Turkey gum*. It is imported in casks, boxes, bags, and also in skins. The importation of gum arabic into the United States has risen to over 3,000,000 pounds annually.

Description.—Gum arabic occurs in roundish tears of various sizes, but usually more or less broken, and then constitutes angular fragments, of a glass-like, somewhat iridescent fracture, opaque in consequence of the numerous fissures contained in it, but transparent in thin pieces. The finest quality is colorless or white in mass, the pieces exhibiting more or less of a yellowish or brownish tint being the inferior varieties.

It has a very faint odor and a mucilaginous insipid taste. It is completely insoluble in strong alcohol, but dissolves in 2 parts of water, forming a thick transparent mucilage of an acid reaction; this solution is not precipitated by lead acetate, but subacetate of lead and soluble silicates yield white precipitates, and borax and ferric salts gelatinize the solution. Its specific gravity varies between 1.355 and 1.491; when completely dried at 100° C. (212° F.) it is increased to 1.525, with an absolute loss of 13.14 per cent. (Flückiger).

Savakin gum, which is quite brittle, is often not entirely soluble in water, but yields with it a pasty mass of rather strong acid reaction, depositing, when diluted with water, transparent globules, which Reimann (1881) found to consist of metagummic acid; this may be rendered soluble by the addition of a little potassa or by lime-water.

For pharmaceutical purposes only the whitest gum should be used, but in the arts the colored gums are frequently quite as serviceable, and their solutions are decolorized by filtering through aluminum hydrate, or by treatment with sulphurous acid, followed by barium carbonate.

Composition.—Gum arabic or arabin is the calcium compound of *arabic* or *gummic acid*, but contains also magnesium and potassium. This acid, which has been found by Scheibler (1873) in the sugar-beet, and is identical with Frémy's *metapeptic acid*, may be obtained pure by precipitating with alcohol the mucilage, previously acidulated with

hydrochloric acid, washing the precipitate well with alcohol and repeating the operation several times. While still moist, gummy acid is soluble in water, and from this solution it is not precipitated by alcohol unless hydrochloric acid be added. After drying (metagummic acid of Frémy) it merely swells up, but does not dissolve either in cold or boiling water, in which it is rendered soluble again on the addition of alkalies. It is amorphous, and after drying at 100° C. (212° F.) its composition is $C_{12}H_{22}O_{11}$; treated with lime-water and alcohol, the compound $C_{12}H_{20}(CaO)_{11} : 5C_{12}H_{22}O_{11}$ is obtained (Neubauer, 1854). This contains 2.56 per cent. $CaO = 4.58$ $CaCO_3$. Löwenthal and Hausmann (1853) obtained 3.17 to 3.30 per cent. of ashes from gum arabic. Solution of gum rotates polarized light usually to the left, but some kinds have a right rotation. By continued boiling with dilute sulphuric acid, sugar is produced; nitric acid oxidizes it to mucic, saccharic, tartaric, and oxalic acids. Some gums yield little or no mucic acid, and these, on being treated with dilute sulphuric acid, produce *arabinose*, $C_{12}H_{22}O_{11}$, which crystallizes from hot alcohol in groups of minute radiating prisms, is not fermentable, but reduces Fehling's solution like grape-sugar. It was discovered by Scheibler in 1868, and obtained also from the gum of the juice of the sugar-beet. Kiliani (1880) regarded the sugar as identical with lactose. But Claësson (1881) proved it to be distinct from the latter; however, from gums which yield much mucic acid a sugar was obtained corresponding in the main with lactose. Reichardt's *pararabin* (1875) is a constituent of the sugar-beet, soluble in warm dilute acids, swelling with water, and by long-continued boiling with alkalies converted into arabic acid.

The inferior qualities of gum contain a little grape-sugar, which may be removed by alcohol; thus purified, gum does not reduce alkaline solutions of cupric oxide. 3 Gm. Kordofan (and Senegal) gum, precipitated from its aqueous solution by an excess (15 grams) of solution of subacetate of lead, yield a scarcely opalescent filtrate, which remains almost clear with ammonia. The filtrate yielded under similar circumstances from Senaar gum is slowly obtained, is milky, and yields with ammonia a gelatinous precipitate (Schlosser, 1869).

Other Varieties of Gum.—SAVAKIN or SUAKIN GUM, which is described above, is also known as *talea* or *talha gum*, and is the exudation of *Acacia stenocarpa*, Hochstetter, and *A. fistula*, Schweinfurth.

GUM SENEGAL derives its name from the river Senegal. It is the product of *Acacia Verek*, A. Adansonii, *Guillemin et Perottet*, and other species of *Acacia* growing in Senegambia and adjoining countries of Western Africa. It occurs often in elongated and larger tears than the Egyptian gum, which mostly vary in color between yellow and brownish-red, have few fissures, but occasionally air-cavities in the centre, and otherwise have the appearance and chemical properties of gum arabic. A variety called *gum Galam*, *gomme du bas du fleuve* in France, is lighter in color, and has not the bitterish taste often found in the ordinary kind. Senegal gum enters commerce through France, where it is officinal; it is extensively used in the arts. From 5,000,000 to 6,000,000 pounds are gathered annually, the principal collection commencing in March (Féraud, 1873).

GUM MOCADOR, named after the port in North-western Africa whence most of it is exported from Morocco, also known as *Morocco* and *Barbary gum*, is probably obtained from *Ac. nilotica*, Desfontaines. It is in irregular tears of a yellowish-brown to red-brown color, superficially fissured, but breaking with a glass-like fracture.

CAPE GUM, imported from the Cape of Good Hope, exudes from *Acacia horrida*, Willdenow, occurs in small tears and fragments, and is of a pale-yellow to amber color.

AUSTRALIAN GUM, WATTLE GUM, the produce of *Acacia decurrens*, Willdenow, A. pyrantha, Benthon, and other species, is found in tears, which are frequently quite large, vary in color from yellowish to reddish-brown, have a slightly astringent taste, and break with a glass-like fracture.

MEZQUITE GUM is obtained from *Algarobia* (*Prosopis*, Gray) *glandulosa*, Torrey & Gray, s. *Prosopis juliflora*, De Candolle, a tree 20 to 40 feet (6–12 M.) high, indigenous to Texas, New Mexico, and California, and southward through Mexico to Chili and Buenos Ayres; the yield by natural exudation is increased by making incisions; it is collected during the months of July, August, and September. It occurs in tears varying in size and in color from colorless to amber-brown, and resembles gum arabic in the fissures, specific gravity, solubility, its behavior to nitric acid, and the amount of ash yielded on incineration, 2.1 to 3 per cent.; but its aqueous solution is not precipitated by subacetate of lead, ferric salts, or borax; acetate of lead, with ammonia subsequently added, yields a gelatinous precipitate. The reactions, however, differ to some extent in different samples, and it is not unlikely that several *Mimoseae* may furnish this gum.

CHAGUAL GUM is collected in Chili from *Pourretia* (Puya, Molina) *lanuginosa*, Ruiz et Pavon, nat. ord. Bromeliaceae, and yields a thick acidulous mucilage, which is precipitated by lead acetate, but not by borax or silicates. About 20 or 25 per cent. of the gum is insoluble in water.

HOG GUM, DOCTOR GUM, comes from South America, in translucent or transparent reddish irregular tears, which are but partly soluble in water. It is usually referred to *Rhus Metopium*, Linné, by others to *Moronebea coccinea*, Aublet, both of which yield gummy exudations. It is

not identical with HOGG GUM or KUTEERA GUM, which, according to Royle, is obtained from *Cochlospermum Gossypium*, *De Candolle*, nat. ord. Bixaceae, but appears also to be collected from *Acacia leucophloea*, *Willdenow*, and probably from other trees. It is exported from India, and closely resembles the inferior kinds of tragacanth; its solution in water is neutral; the portion insoluble in water yields with alkalis a thick mucilage of a pinkish color, which according to Mitchell (1880) is not precipitated by acids.

Adulterations and Substitutions.—The inferior kinds of gum described above are frequently substituted for gum arabic in tears. In powder it is liable to the same substitution, and also to adulteration with flour and dextrin. The former is easily detected by adding to the cold mucilage, prepared with hot water, a solution of iodine, when a blue color will be produced; the latter by Trommer's test, which will separate cuprous oxide at ordinary temperature in an hour or two, or immediately on heating.

Pharmaceutical Uses.—Powdered gum arabic is extensively used in the preparation of emulsions of oleoresins, fixed and volatile oils, also for forming troches and pills; for the latter purpose a solution of gum in glycerin is preferable, particularly if the pills are to be kept for some time. Gum arabic is preferably made into a moderately fine powder (*sanded gum*), which retains its ready solubility in water; by drying it so that it may be finely powdered, it loses nearly 10 per cent. in weight, does not dissolve rapidly, and reduces alkaline copper solutions (Hager, 1873).

PASTA GUMMOSA s. **PASTA ALTHÆÆ**, Marshmallow paste, *E.*; *Pâte de gomme*; *P. de guimauve*, *Fr.*; *Gummipaste*, *G.* Dissolve 1000 Gm. of white gum arabic in 1000 Gm. of water, strain, add 1000 Gm. of sugar, and with continuous stirring, evaporate in a water-bath to the consistence of thick honey; then add gradually 100 Gm. of orange-flower water and the white of 12 eggs, previously well beaten; continue to beat the mixture until of proper consistence; let it cool upon a marble slab or in boxes, and keep it in a mixture of 3 parts of powdered starch and 1 of sugar.—*F. Cod.*

Off. Prep.—*Mistura amygdalæ*, *U. S.*; *Mist. cretæ*, *U. S.*, *Br.*; *Mist. glycyrrhizæ composita*, *U. S.*; *Mist. guaiaci*, *Br.*; *Mucilago acaciæ*, *U. S.*, *Br.*; *Pulvis amygdalæ compositus*, *P. tragacanthæ compositus*, *Br.*; *Trochisci*, *Br.*, *U. S.*; *Syrupus acaciæ*, *U. S.*

Other Products of Acacia (see also **CATECHU**).—The *sabicu*-wood of Cuba, from *A. formosa*, *Kunth*, the *blackwood* of Australia, from *A. melanoxylon*, *R. Brown*, the fragrant *myall*-wood of Australia, from *A. homalophylla*, *Cunningham*, and others, are valuable for cabinet and other work.

ACACIA FARNESIANA, *Willdenow*, is indigenous to the tropical and subtropical parts of America, and is cultivated in Southern Europe for the fragrant flowers, which yield a delicious perfume. In Germany the flowers of the *sloe*, *Prunus spinosa*, *Linné*, are also known as *flores acaciæ*.

Physiological Action and Medical Uses.—Various observations on the use of acacia as food, and experiments upon animals that were kept exclusively upon a diet of this substance, appear to render it probable that it cannot contribute much to real nutrition—that is, by providing materials for forming tissue. It is certain that an exclusive diet of gum cannot sustain life. Yet it may possibly retard waste, and thereby prolong life. Such appears to be in part its operation when used by the sick in the form of gum-water. But unquestionably its more demonstrable merit consists in its serving as a protective to inflamed surfaces, such as the mucous membrane during *pharyngitis*, *laryngitis*, etc., when it is usually given in the form of troches or lozenges. In *febrile* affections generally, in *inflammations* of the gastro-intestinal mucous membrane, in *gastritis*, *typhoid fever*, *dysentery*, etc., it is in ordinary use. In all such cases it is a palliative of irritation. By coating the mucous membrane, it moderates the irritation which the contents of the intestine tend to maintain, and thereby checks *diarrhœa* and tends to constipate. Its solution (*mucilago acaciæ*) may be rendered more agreeable and useful by the addition of sugar and various flavoring syrups; or the syrup, which is officinal, may be used alone. Powdered acacia may be applied to arrest bleeding from leech-bites and other sources of slight *hemorrhage*. Its thick mucilage is sometimes used as a protective for superficial *burns*, *excoriations*, and *ulcers*.

ACETONUM.—ACETONE.

Spiritus (s. *Ether*) *pyroaceticus*.—*Pyroacetic spirit or ether*, *E.*; *Acétone*, *Éther* (*Esprit*) *pyroacétique*, *Fr.*; *Aceton*, *Essiggeist*, *Mesitalkohol*, *G.*

Formula C_3H_6O . Molecular weight 58.

Formation and Preparation.—Acetone is formed on the dry distillation of wood,

of acetates, citric acid, and, in the presence of lime, from sugar and other carbohydrates. It is obtained pure by the dry distillation of barium acetate (Liebig), but is usually prepared from calcium acetate or from a mixture of 4 parts of crystallized acetate of lead and 1 of burnt lime; the distillate is neutralized with dry sodium carbonate, treated with calcium chloride, and purified by fractional distillation over lime.

Properties.—It is a thin, colorless liquid, which when ignited burns with a luminous, non-sooty flame. It has a peculiar ethereal somewhat mint-like odor, and a refreshing, but very pungent and sweetish taste. Its density at 15° C. (59° F.) is .8008, and at 18° C. (64.4° F.) .792; it boils between 55.5° and 56.3° C. (132° and 133.3° F.). It is soluble in all proportions in water, alcohol, ether, volatile oils, and most compound ethers, and dissolves gun-cotton, camphor, many resins, including copal, and fats. Most of the salts soluble in alcohol are insoluble in acetone, which separates even from a concentrated aqueous solution of calcium chloride.

Composition.—The empirical formula has been given above. Constitutionally it has been regarded as aldehyd, with 1H replaced by methyl = $C_2H_3(CH_3)O$; also as *dimethyl-ketone* $CO.CH_3.CH_3$.

Impurities.—The principal impurities met with in acetone are alcohol and water, which impart a higher specific gravity; the former may be recognized by the addition of iodine, followed by potassa solution, when iodoform will be separated. Water, if present, will liquefy a fragment of calcium chloride, but the same salt powdered, according to Hlasiwetz (1850), will form with acetone a solid compound which is decomposed by water. Empyreumatic products present in acetone will cause an opalescence on dilution with water.

Allied Compound.—ACETAL, $C_6H_{14}O_2$ or $CH_3CH(C_2H_5O)_2$; mol. weight 118. It is formed on the oxidation of alcohol by manganese dioxide and sulphuric acid, or by platinum black or by chlorine, and is obtained by fractional distillation and by treatment with calcium chloride and potassa. It is a thin, colorless liquid, of an agreeable alcohol-like odor, a refreshing taste, and the specific gravity .831 at 20° C. (68° F.). It boils at 104° C. (219.2° F.), dissolves in alcohol and ether in all proportions, but is rather sparingly soluble in water. In contact with air and by oxidizing agents it is readily converted into aldehyd, and finally into acetic acid.

Medical Action and Uses.—This preparation was originally employed in chronic *pulmonary affections* to allay cough and diminish expectoration; but it has long been disused for these purposes. It is asserted to act, not as an anæsthetic, but as a soporific only; but the better opinion is that, while its anæsthetic action is comparatively feeble, its intoxicating operation is decided. It has been recommended as an *anthelmintic*, and in *rheumatism* and *gout*. It may be prescribed in doses of 15 or 20 drops (Gm. 1.0–1.30), dissolved in spirit of nitrous ether. It may also be used by inhalation from a watery solution, either atomized or diffused by heat.

ACETAL, according to Von Mering, acts first on the brain, causing gradual loss of consciousness, and then upon the spinal marrow, arresting respiration before the heart. When fatal it kills by asphyxia. Miller reports that its internal administration is not easy, since its taste is acrid and burning, and, moreover, that it is six times as weak as chloral hydrate, acting as a hypnotic only in doses of from 2 to 3 drachms (Gm. 8–12). On the day after taking it patients complained of depression, heaviness of the limbs, and nausea (*Zeitschrift f. klin. Med.*, vi. 492).

ACETUM, Br., P. G.—VINEGAR.

Acetum crudum, Acetum vini.—Vinaigre, Fr.; Essig, G.

Vinegar is a dilute acetic acid, obtained by the acetic fermentation of alcoholic liquids; the materials from which it is prepared influence its color, and to a considerable extent also its odor and taste.

Production.—Wine, cider, beer, and similar liquids not containing too large an amount of alcohol, when exposed to the atmosphere, turn sour in consequence of the oxidation of alcohol, to acetic acid; $C_2H_6O + O_2$ yields $C_2H_4O_2 + H_2O$. This acetification is accomplished in partly-filled casks having a small opening at the top, and requires several weeks or months, or even about two years, to be complete, according to the temperature, which is most suitably kept between 20° and 35° C. (68° and 95° F.). During this process a cryptogamic growth is observed, consisting, according to Pasteur, of *Mycoderma aceti*. The acid liquid thus obtained requires clarification, which is effected either by allowing it time to settle or by transferring it to other casks containing wood shavings. In this manner, *wine, cider, malt, and beer vinegars* are made.

Most generally, however, vinegar is made by the so-called *German* or *quick vinegar process*, for which the simple apparatus suggested by Wagenmann is employed. This consists of several straight-sided casks 6 to 9 feet high, having, a few inches above the bottom, a false bottom or perforated diaphragm, upon which is packed a layer, 2 to 3 feet in thickness, of fresh beech-wood shavings which have been previously steeped in vinegar. Several inches below the top another perforated diaphragm is inserted, or, in place of it, the cask is covered with a well-fitting tub having a perforated bottom.* The liquid, containing from 6 to 10 per cent. alcohol, being placed upon the upper diaphragm, its flow is regulated by means of wooden pins inserted into the perforations, and it is thus compelled to trickle through the shavings, and thereby to present a large surface to the oxidizing influence of the atmosphere, with which free communication is established by a number of holes bored through the side of the cask immediately above the lower diaphragm, and by several tubes passing through the upper diaphragm and above the surface of the alcoholic liquid. The partly aceticified liquid is drawn off from below the lower false bottom by means of a tap or pipe, and transferred to another similarly prepared cask, until the whole of the alcohol has been converted into acetic acid. During all this time the change of air in the room and its temperature must be carefully attended to, as otherwise the oxidation may become too rapid and the heat within the casks too high, so that the alcohol would be oxidized into carbonic acid and water. At and below 7.2° C. (45° F.) little or no acetic acid is produced. The process is finished in from 3 to 15 days.

Theory of Acetification.—Ethyllic alcohol C_2H_6O is first oxidized to aldehyd acetylaldehyd, or acetylhydride, with the elimination of water; $C_2H_6O + O = H_2O + C_2H_4O$. By the further acquisition of oxygen, acetic acid $C_2H_4O_2$ is formed. These oxidations are brought about, according to Pasteur, through the agency of the *Mycoderma* above referred to, while others ascribe it mainly to the oxidizing influence of the air; according to Mulder the appearance of *Mycoderma aceti* in vinegar is accompanied by a decrease of the acetic acid.

Properties.—Made by the German process, vinegar generally contains some aldehyd and alcohol, which are usually absent if the production has been effected by the slow oxidation in casks. The sensible properties of vinegar are affected to a much larger extent by the material from which it has been obtained. *Malt vinegar* is largely made in Great Britain from beerwort, or from the fermented solution of malt; it is of a more or less deep-brown color. *Beer vinegar* made from stale beer has the bitter taste of the hops.

Wine vinegar is very extensively made in Southern and Western Europe from the lower grades of wines, the aroma of which is, to some extent, preserved; it contains also tartaric acid and tartrates, and if made from a red wine possesses a red color. *Cider vinegar*, which is much employed in the United States, is made from cider, and contains malic acid. *Common vinegar*, made from diluted whiskey, has the flavor of the latter to some extent, and contains the alkaline and earthy salts of the water used in its manufacture.

The color of vinegar varies from yellowish to brown or red; its specific gravity is about 1.008 to 1.018. It has an agreeable acidulous odor, differing from that of diluted acetic acid by the presence of some acetic or other ethers. By exposure to the air it undergoes putrefaction and becomes muddy. It should contain between 5 and 6 per cent. of acetic acid. A fluidounce of it should require for neutralization not less than 35 grains of bicarbonate of potassium (*U. S.*, 1870), indicating $4\frac{1}{2}$ per cent. 445.4 grains by weight require at least 402 grain-measures of the volumetric solution of soda for neutralization, indicating 5.4 per cent. of acid or 4.6 per cent. of acetic anhydride (*Br.*). 10 Gm. of vinegar neutralize 10 Cem. of volumetric solution of potassa (*P. G.*), indicating 6 per cent. of acetic acid. Evaporated to dryness, a residue amounting to 1 or 2 per cent. is obtained, and on incineration a small amount of ashes, usually between 0.01 and 0.03 per cent., is left behind.

ACETUM DESTILLATUM, Distilled vinegar, *E.*; Vinaigre distillé, Oxéolat simple, *Fr.*; Destillirter Essig, *G.*—*Distilled vinegar* is made by distilling crude vinegar from a glass retort until about three-fourths have passed over. It is colorless, lighter in specific gravity (about 1.004), owing to the removal of extractive and other substances, and should contain not less than 4.5 per cent. of acetic acid. *Acetum purum s. destillatum* of the German Pharmacopœia is equivalent to the diluted acetic acid *U. S. P.*

Impurities and Adulterations.—Poisonous metallic salts, like tin, lead, and copper, which may be present as accidental impurities, are detected by the dark coloration or precipitate occurring with hydrosulphuric acid; moreover, copper would be precipitated upon a bright iron spatula kept in the vinegar for a short time; lead, if present, will yield a white precipitate with sulphuric acid, and a yellow one with potassium iodide.

Acrid substances, such as capsicum, pepper, pellitory, ginger, etc., which may have been added to impart artificial strength, are recognized by the taste of the vinegar after it has been neutralized with an alkali, or after it has been evaporated in a water-bath to a syrupy consistence.

The most common adulterations are acids, and particularly sulphuric acid. In testing for these it must be remembered that crude (but not distilled) vinegar is likely to contain sulphates, chlorides, and occasionally even nitrates, derived from the water which has been used in its manufacture. *Sulphuric acid* is detected by the white precipitate yielded on boiling with chloride of calcium, which is not precipitated by the small amount of sulphates present. On evaporating the vinegar and mixing with the extract, while still warm, a little powdered potassium chlorate, an ignition will be observed in the presence of free sulphuric acid, or if its quantity be minute the odor of chlorine will be produced (J. C. Wharton, 1882). A more delicate test is that of Chevallier, which was in 1872 again suggested by James T. King: an ounce of vinegar is evaporated to half a drachm, an ounce of alcohol is added, which removes all traces of sulphates; the liquid is now filtered, mixed with an ounce of water, and may be either directly tested with a solution of chloride of barium in diluted alcohol, or the alcohol may be previously evaporated at a moderate temperature. W. C. Young (1877) has proposed to add to 30 Ccm. of vinegar some barium chloride in excess, estimate the chlorine in one-third of the liquid, and then evaporate the other two-thirds to dryness, incinerate, and determine the chlorine in the ashes. The difference between the two results, calculated for the same quantity of vinegar, is due to hydrochloric acid, liberated by an equivalent quantity of free sulphuric acid. *Hydrochloric acid* is recognized by the distillate producing a white turbidity or precipitate with nitrate of silver, which is not removed by nitric acid, but is soluble in ammonia. *Oxalic acid*, if present, occasions with chloride of calcium at once a white precipitate, which is dissolved by nitric acid. *Tartaric acid* is best recognized by concentrating the vinegar in a water-bath, evaporating it to one-fourth or one-sixth of its volume, filtering and adding a concentrated solution of acetate of potassium, when acid potassium tartrate will be precipitated. *Nitric acid* may be detected by evaporating the vinegar in a water-bath to one-third its volume, and digesting it with copper filings, when nitrous acid vapors will be given off, which are recognized by the red color. Since a solution of ammonium acetate, on being evaporated in a water-bath, leaves no residue, about an ounce of vinegar (30 Gm.) may be mixed with a slight excess of ammonia and evaporated, when merely an extractive mass should be left; but if crystalline, one or more of the above-mentioned acids are present. According to Chiappe (1882), a very simple test for the presence of mineral acids is methyl-aniline-violet or Paris violet, the color of which is not affected by organic acids, but is changed to ultramarine blue by inorganic acids; a solution of the dye in 1000 parts of water or alcohol is used for testing.

The presence of *aldehyd* in vinegar is indicated by the brown color produced in the first portion of the distillate with an excess of potassa solution. Vinegar which has been prepared or kept in oaken barrels contains a little tannin, and acquires a black color with ferric salts.

Distilled vinegar should not be colored by an excess of potassa; it should not on heating destroy the blue tint occasioned by indigo solution (*nitric acid*), not leave any residue on evaporation, and not occasion any precipitates with chloride of barium or nitrate of silver.

Pharmaceutical Uses.—Crude vinegar is now rarely employed in pharmacy, and in place of distilled vinegar dilute acetic acid is usually used.

ACETUM AROMATICUM, *P. G.*; Aromatic vinegar, *E.*; Vinaigre aromatique, *V. vulnéraire*, *Fr.*; Aromatischer Essig, *G.* Oil of Lemon, Oil of Cloves, each 2 parts; Volatile Oils of Lavender, Peppermint, Rosemary, Juniper, and Cinnamon, each 1 part; Alcohol 300 parts; Acetic Acid 450 parts; Water 1200 parts; dissolve, set aside for several days and filter. It is a clear, colorless liquid, of an aromatic acetous odor, and miscible with water in all proportions without becoming turbid. (See also ACIDUM ACETICUM.)

Off. Prep.—Emplastrum cerati saponis, *Br.*

Physiological Action.—Vinegar is a mild stimulant and astringent, but distilled vinegar more nearly resembles acetic acid in the energy of its action. The universal employment of vinegar as a condiment, to facilitate the digestion of crude vegetable and fatty animal food, proves that it is useful for these purposes. Its favorable action is supposed to depend upon its power of softening and promoting the solution of animal fibre and converting cellulose into sugar. The latter explanation may be well founded, but the former does not apply to the utility of the liquid as a condiment for fatty sub-

stances. It seems not improbable that, as vinegar powerfully excites the secretion of the salivary glands, it exerts a similar influence on the stomach, augmenting the flow of gastric juice, and thereby increasing the digestive power of the organ. It is probable that, in a similar manner, it moderates thirst, a purpose to which it has always been applied by the laity as well as by physicians. Like other stimulants, if used in excess it exhausts the susceptibility of the stomach, impairs digestion and nutrition, and may induce a state of marasmus accompanied by degenerative changes in the lungs, and ending in fatal phthisis. Such effects have resulted from the excessive use of vinegar for the purpose of restraining a tendency to obesity. After death, in some cases of this sort, the stomach itself has been found to present the lesions of chronic gastritis. Experience has shown that, as a condiment, vinegar is most suitable for fat and plethoric persons, and in warm weather. It should be very sparingly used by the thin and anæmic, and by those who are subject to diarrhœa. Its tendency to affect the milk of nursing mothers and occasion diarrhœa in their infants should be constantly kept in mind. Applied to the skin, vinegar by its evaporation causes a sense of coolness, even while it produces some irritation and stimulates the cutaneous blood-vessels and glands.

Medical Uses.—In common with other acids, vinegar possesses the property of assuaging thirst, and hence it has always been used for this purpose in *fevers*. It appears also to diminish the frequency of the pulse and the heat of the skin in these affections. Its power of preserving animal and vegetable substances immersed in it probably led to the notion that it possesses special virtues in the falsely-called putrid fevers, and especially that it prevents contagion. But these notions are groundless. In those affections, however, the use of vinegar as a lotion is useful by the evaporation of the liquid producing a refreshing sense of coolness. Probably, also, its stimulant action upon the skin may promote a salutary diaphoresis. It is an error to suppose, as the ancients did, that vinegar is an antidote to the poisonous effects of *narcotics*; its stimulant action may be advantageous when the poison has been removed from the system and its direct operation has ceased. In this respect, however, it is greatly inferior to ammonia, coffee, and even alcohol. When given after the ingestion of caustic *alkalies* or earths, or of the carbonates of these substances, it unites with them, and, forming innocuous acetates, arrests their corrosive action. Vinegar and dilute acetic acid have been used beneficially in the treatment of *lead colic* after the bowels had been moved by purgatives. The stimulant action of strong vinegar or dilute acetic acid is usefully employed by snuffing the fumes of these liquids, to which camphor and various aromatics have been added. This expedient is useful in relieving *nervous headache*, *faintness*, *drowsiness*, *commencing coryza*, etc., but is less efficient than a similar application of ammonia. Vinegar, distilled or not, is a very useful agent for arresting *hæmorrhage*, especially from the nose, stomach, rectum, and uterus. It should, if possible, be applied directly to the source of the bleeding, as in post-partum hæmorrhage by expressing vinegar from a sponge introduced into the cavity of the uterus. At the same time compresses saturated with vinegar and water should be laid upon the abdomen. Vinegar is popularly employed to prevent *discoloration* of the skin after injuries of the integument, and to retard the redness and swelling and allay the pain of local *inflammations*. This method is particularly useful in superficial *burns* and in preventing *suppuration* of the mamma. A weak solution of vinegar may be used to limit the action of particles of *lime* in the eye. Lotions of vinegar check *colliquative perspiration*, and produce a refreshing coolness when the skin is hot in *fevers*, and allay *headache* and *delirium* when applied to the forehead. Enemas of vinegar are sometimes used to destroy *ascarides* of the rectum.

The *dose* of vinegar is from 1 to 4 fluidrachms (Gm. 4–16) in from 2 to 4 parts of water. An acidulated drink may be made with 2 fluidounces (Gm. 64) of vinegar in a quart (Gm. 1000) of water. By enema vinegar may be given to the extent of from 1 to 4 fluidounces (Gm. 30–130). A lotion may be made with 1 part of vinegar and 3 or 4 of water. The doses of distilled vinegar do not differ materially from the above.

ACETUM CANTHARIDIS, Br.—VINEGAR OF CANTHARIDES.

Vinaigre cantharidé, Fr.; Canthariden-Essig, G.

Preparation.—Take of Cantharides in powder 2 ounces; Glacial Acetic Acid 2 fluidounces; Acetic Acid 18 fluidounces, or a sufficiency. Mix 13 fluidounces of the acetic acid with the glacial acetic acid, and digest the cantharides in this mixture for 2

hours at a temperature of 93.4° C. (200° F.); then transfer the ingredients after they have cooled to a percolator, and when the liquid ceases to pass pour 5 ounces of acetic acid over the residuum in the apparatus. As soon as the percolation is complete, subject the contents of the percolator to pressure, filter the product, mix the liquids, and add sufficient acetic acid to make 1 pint (Imp. meas.).—*Br.*

At the elevated temperature directed in this process the cantharidin, with various extractive matters, is readily dissolved by the acetic acid, and after cooling remains in solution.

Medical Action and Uses.—Vinegar of cantharides is irritating to the skin by means of both its constituents. Like other strong liquid vesicants, it is especially appropriate when the surface to be blistered is uneven and of very limited extent, and when it is an object to produce vesication rapidly. It is more painful than other vesicating preparations of cantharides. It should be applied with a brush in several successive coats, and then covered with some simple ointment. Vesication usually occurs within 2 or 3 hours. It is very suitable for blistering the skin over the superficial portions of nerves in *neuralgia*, as was first recommended by Cotugno, and more recently systematized by Valleix; and also for blistering in *rheumatism* after the manner of Herbert Davies.

ACETUM LOBELIÆ, U. S.—VINEGAR OF LOBELIA.

Vinaigre de Lobélie enflée, Fr.; *Lobelien-Essig*, G.

Preparation.—Take of Lobelia in No. 30 powder 10 parts (1 oz. av.); Diluted Acetic Acid sufficient. Moisten the powder with 5 parts ($\frac{1}{2}$ oz. av.) of the acid, pack it firmly in a conical glass percolator, and gradually pour upon it diluted acetic acid until 100 parts (10 oz. av., or about 9 $\frac{1}{2}$ fluidounces) of percolate are obtained.—*U. S.* This vinegar is about one-fourth weaker than that of the Pharmacopœia of 1870.

It is a reddish-brown liquid, in which the alkaloid lobeline is supposed to be preserved from alteration by the free acetic acid.

Medical Action and Uses.—The advantages of this preparation appear to be its stability and strength. It is especially indicated in congested states of the *bronchial* mucous membrane, with imperfect secretion and *spasmodic constriction* of the air-tubes. It may be appropriately associated with preparations of antimony, squill, seneka, or ipecacuanha. The dose for an adult is from 30 minims to a fluidrachm (Gm. 2–4) when a merely expectorant operation is desired; but as a nauseant and antispasmodic, from 1 to 2 fluidrachms (Gm. 4–8) should be given at intervals of an hour until its characteristic effects are produced.

ACETUM OPII, U. S.—VINEGAR OF OPIUM.

Black drop, E.; *Vinaigre d'Opium*, Fr.; *Opium-Essig*, G.

Preparation.—Take of powdered Opium 10 parts (1 oz. av.); Nutmeg in No. 30 powder 3 parts (131 grains); Sugar 20 parts (2 oz. av.); Diluted Acetic Acid sufficient to make 100 parts (10 oz. av., or about 8 $\frac{1}{2}$ fluidounces). Macerate the opium and nutmeg in 50 parts (5 oz. av.) of the acid for 24 hours. Put the mixture into a conical glass percolator, and return the liquid until the percolate passes clear. Then pour on diluted acetic acid until 80 parts (8 oz. av., or about 7 $\frac{1}{2}$ fluidounces) of liquid have been obtained. In this dissolve the sugar, without heat, and strain.—*U. S.*

This is, by measure, the strongest of the liquid preparations of opium, but is about one-third weaker than that of the preceding Pharmacopœia, 1 grain of opium being represented by 10 grains (or by about 9 minims) of the vinegar. It is of a deep reddish-brown color.

Medical Action and Uses.—Vinegar of opium is nearly free from the sickening smell and taste which belong to laudanum, and is much less apt to nauseate. This last quality is probably due in part to the nutmeg it contains, and in part to the almost complete absence from it of narcotine, the most irritating to the stomach and depressing to the nervous system among the constituents of opium. This advantage it shares with the deodorized tincture. The dose is from 5 to 10 drops or minims (Gm. 0.30–0.60).

ACETUM SANGUINARIÆ, U. S.—VINEGAR OF SANGUINARIA.

Vinaigre de Sanguinaire, Fr.; *Blutwurzels-Essig*, G.

Preparation.—Take of Bloodroot in No. 30 powder 10 parts (1 oz. av.); Diluted Acetic Acid sufficient. Moisten the powder with 5 parts ($\frac{1}{2}$ oz. av.) of the acid, pack it

firmly into a conical glass percolator, and gradually pour upon it diluted acetic acid until 100 parts (10 oz. av., or about 9¼ fluidounces) of filtered liquid are obtained.—*U. S.*

Recently prepared, this vinegar is of a deep-red color, which becomes lighter on standing, owing to the deposition of coloring matter, which appears to be independent of that due to the sanguinarine salt (Procter, 1864).

Medical Action and Uses.—The very limited use of this preparation prevents any definite knowledge of its peculiar virtues. Whatever utility it may have displayed as a gargle in *scarlatinous sorethroat* was probably due to its menstruum. It would be folly to employ it as an emetic when other more certain emetics are at hand; and there is nothing to show that as an expectorant, which it is reputed to be, its beneficial action outweighs its harsh operation and its depressing action on the heart and nervous system. Its dose as an emetic is stated to be 3 or 4 fluidrachms (Gm. 12–16), and as an alterative and expectorant, from 15 to 30 drops or minims (Gm. 1–2).

ACETUM SCILLÆ, *U. S., Br., P. G.*—VINEGAR OF SQUILL.

Vinaigre scillitique, Fr.; *Meerzwiebel-Essig*, G.

Preparation.—Take of Squill in No. 30 powder 10 parts (1 oz. av.); Diluted Acetic Acid sufficient. Mix the powder with 30 parts (3 oz. av.) of the acid, and when the mixture has ceased to swell pack it carefully into a conical glass percolator, and gradually pour upon it diluted acetic acid until 100 parts (10 oz. av., or about 9¼ fluidounces) of filtered liquid are obtained.—*U. S.*

Powdered squill forms a solid mass with a small amount of aqueous liquids, and absorbs a much larger amount, increasing thereby considerably in bulk. For 10 parts of the powder 40 parts of dilute acetic acid may be used without disadvantage previous to introducing it into the percolator. The moist coarse powder should be carefully packed, a moderate amount of pressure being used, so that the liquid will penetrate uniformly and pass through in drops. The British, French, and German Pharmacopœias direct this preparation to be made by maceration, that of the latter being practically identical with, that of the former somewhat stronger than, that of the present *U. S. P.* The formula of the British Pharmacopœia is as follows: Macerate 2½ ounces of bruised squill in an imperial pint of diluted acetic acid for 7 days, strain with expression, add to the strained liquid 1½ fluidounces of proof spirit, and filter. The German Pharmacopœia macerates 5 parts of squill in 5 parts of alcohol, 9 parts of acetic acid, and 36 parts of water for 3 days. The French Codex directs 1 part of squill to be macerated in 12 parts of white vinegar for 8 days.

Off. Prep.—Oxymel scillæ, *Br.*; Syrupus scillæ, *U. S., Br.*

Medical Action and Uses.—Vinegar of squill was anciently employed, and for very diverse purposes, among which it is only necessary to mention the cure of spongy gums, various forms of sorethroat, hoarseness, etc., in all of which it is certain that the vinegar, and not the squill, in the compound was the efficacious ingredient. The diuretic action of squill is probably enhanced by its solution in vinegar, which is the best form for its administration in *dropsy*. Its efficiency is much increased by associating it with acetate of potassium and digitalis, as in the following formula: ℞. Tinct. scillæ fʒss; tinct. digitalis fʒij; spt. juniperi comp., vin. hispan., aa fʒij; aquæ fʒviij; potassii acetat. ʒj.—*M. S.* A tablespoonful, diluted, three times a day. Vinegar of squill should not be used in renal dropsy, but only in dropsy of cardiac origin. Its average dose is about 15 minims (Gm. 1), and it is best administered in an aromatic draught.

ACHILLEA.—YARROW.

Herba s. Summitates achillæ s. millefollii.—*Milfoil*, E.; *Millefeuille*, *Herbe aux charpentiers*, Fr.; *Schafgarbe*, *Schafrippe*, G.

Achillea Millefolium, *Linné*. Woodville, *Med. Bot.* 15; Bentley and Trimen, *Med. Plants*, 153.

Nat. Ord.—Compositæ, Senecionidææ.

Description.—A perennial herb, 2 to 3 feet (60–90 Cm.) high, growing in fields and pastures throughout the greater part of the northern temperate zone of America and Europe. The hairy furrowed stem is nearly simple, branching only near the top. The radical leaves are petiolate, 8 to 12 inches (20–30 Cm.) long; the stem-leaves nearly sessile, 2 to 4 inches (5–10 Cm.) long, all more or less soft-hairy, dark-green, lanceolate in outline, and twice or thrice deeply pinnatifid; the segments are linear-spatulate, three- to five-

cleft, crowded, finely mucronate, and upon the lower side with small oil-glands. The flowers grow in level-topped corymbs; heads numerous, with the involucre oblong; scales imbricate, keeled; receptacle flat, chaffy; ray-florets pistillate, 4 or 5, short ligulate, white or rose-colored; disk-florets several, perfect, tubular, with the margin whitish and the tube greenish; akenes flattened, oblong, without pappus. It has a feeble aromatic somewhat chamomile-like odor, and a bitterish, rather saline taste. It should be collected in July, while flowering, the coarse stems being rejected. The loss in drying is about 85 per cent.

Constituents.—Yarrow yields by distillation with water about $\frac{1}{10}$ per cent. of a blue or dark-green volatile oil, that of the flowers having a spec. grav. of 0.92, that of the leaves .85 to .92, the latter being butyraceous. The bitter principle *achillin* was obtained by Zanon (1846) as a reddish-brown extract-like mass, and was regarded by Von Planta (1870) as being identical with the alkaloid achilleine of iva (see below). Zanon's *achilleic acid* is acetic acid (Hlasiwetz, 1857). Yarrow also contains a small quantity of resin, tannin, and gum, and various salts, consisting of malates, nitrates, phosphates, and chlorides of potassium and calcium; on incineration, from 13 to 17 per cent. of ash is obtained.

Pharmaceutical Preparations.—In Europe an **EXTRACTUM MILLEFOLII** is employed, which is prepared by digesting the drug with diluted alcohol and evaporating. The yield is from 20 to 25 per cent.

Other Species of Achillea.—The following, which are indigenous to Europe, are to some extent employed:

ACH. PTARMICA, *Linné*; Sneeze wort, *E.*; Herbe à éternuer, *Fr.*; Bertramgarbe, *G.* It has been naturalized in some of the New England States. It has lance-linear, finely, but sharply serrate leaves, and elongated white ray florets. The root is sternutatory.

ACH. AGERATUM, *Linné*, has tufted, oblong, serrate, and clammy leaves, and very short ray florets; its odor is strong, but not agreeable; taste bitter.

ACH. NOBILIS, *Linné*, is softly pubescent, has oval or oblong bi- or tri-pinnatifid leaves, with linear-oblong toothed lobes; the 5 ray-florets are reflexed; odor and taste stronger than in the common yarrow.

ACH. MOSCHATA, *Linné*; Iva, *E.*; Génépi blanc, *Fr.*; is largely used in Switzerland; has white flowers and smooth pinnatifid leaves with linear entire lobes; it is strongly aromatic and bitter. Von Planta-Reichenau (1870) obtained from it a bluish-green volatile oil, *ivadol*, of a refreshing odor and bitterish mint-like taste; *ivacin*, $C_{24}H_{42}O_3$, soft, yellow, insoluble in water, soluble in alcohol and bitter; *achilleine*, $C_{30}H_{38}N_2O_{15}$, is readily soluble in water, with difficulty in absolute alcohol, insoluble in ether, and when boiled with dilute acids yields sugar, ammonia, an odorous body, and *achillatine*, $C_{11}H_{17}NO_4$, which is dark-brown, insoluble in water, and not bitter; *moschatine*, $C_{21}H_{27}NO_7$, is insoluble in cold water, and has an aromatic bitter taste.

ACH. ATRATA, *Linné*, and **ACH. NANA**, *Linné*, are used like the other species.

Medical Action and Uses.—Milfoil appears to be a general stimulant and tonic, with peculiar relations to the pelvic organs. Like other stimulant tonics, it has been found capable of curing certain cases of intermittent fever, and is apt to promote the appetite and digestion in atonic gastric disorders. Its special local action is illustrated by the virtues ascribed to it in *piles* and *amenorrhœa*, for the cure of which it was celebrated even in ancient times. The form of the first of these diseases, in which it appears to be most efficient, is that in which, along with relaxation of the sphincter ani, there is a discharge of mucus, more or less bloody, during defecation. A similar condition of atony in the reproductive organs of the female is attended sometimes with *menorrhœgia*, and sometimes with imperfect and painful menstruation. A tonic and stimulant regimen is essential to its successful treatment, and as a portion thereof milfoil may sometimes be employed with advantage. By this mode of action, doubtless, milfoil has proved beneficial in *leucorrhœa* and flatulent *colic*; and it may assist in curing relaxed and otherwise inert conditions of the *throat*, when its infusion is used as a gargle, or in cases of *sore nipples*, when it is applied as a lotion. An infusion may be made with half an ounce (Gm. 16) of milfoil in half a pint of water, reduced by heat to 6 ounces. It may be given in tablespoonful doses every hour. The expressed juice has been prescribed in doses of 1 or 2 fluidounces (Gm. 32–64) three times a day. The volatile oil may be given in doses of 20 drops (Gm. 1.30).

Achillein, in doses of from 8 to 20 grains (Gm. 0.50–1.30), is reported to have occasioned a sense of epigastric oppression and some irregularity of pulse, but to have increased the appetite.

Sneeze wort, as its name implies, is very irritating to the nostrils when applied in powder, and the root, when chewed, produces salivation and an acrid impression on the fauces. These qualities have led to its use in commencing *coryza*, *conjunctivitis*, *pharyngitis*, and

laryngitis. *Musk milfoil* is stated to be stimulant and antispasmodic, and, like *A. atrata*, is used as a stimulant at the commencement of febrile attacks.

ACIDUM ACETICUM, U. S., Br., P. G.—ACETIC ACID.

Acide acétique, Fr.; *Essigsäure*, G.

Formula $\text{HC}_2\text{H}_3\text{O}_2 = \text{CH}_3\text{COOH}$. Molecular weight 60.

Production.—To obtain acetic acid from vinegar, Stahl proposed, about the year 1700, to expose it to cold and separate the stronger acid from the ice, or to neutralize it with an alkali, evaporate, and distil with sulphuric acid. Crystallized acetic acid was observed by the Count de Lauraguais (1759) in the so-called *copper spirit*, the distillate of copper acetate; and Lowitz found that a diluted acetic acid, if repeatedly rectified over powdered charcoal, would yield a product crystallizing at a low temperature, and named it glacial acetic acid. Acetic acid and glacial acetic acid are obtained by the decomposition of an acetate by a stronger acid; for this purpose sodium (or potassium) acetate and sulphuric acid are most generally employed now. The proportions (equal equivalents) adopted already by Stahl, were recently (1873) proven to be correct by Mohr, Buchner, and others also for the preparation of the glacial acid; in this case, however, the mechanical difficulties of the operation are such as to make it preferable to use a larger quantity, nearly 2 equivalents of sulphuric acid. The British Pharmacopœia, 1864, directed fully 2 equivalents; in the last edition, 1867, the process has been omitted. By far the largest quantity of the acetic acid of commerce is now obtained from wood vinegar. Glauber (1648) was already acquainted with vinegar as one of the products of the destructive distillation of wood and other vegetable substances; but the identity of the volatile acid contained therein with that of vinegar from alcoholic liquids was proven by Fourcroy and Vauquelin (1800), and Thénard showed (1802) the same to be contained among the products of the dry distillation of animal substances.

I. Acidum aceticum pyrolignosum, Acidum pyrolignosum.—*Pyroligneous acid*, E.; *Acide acétique du bois*, *acide pyroacétique*, *acide pyroligneux*, Fr.; *Holzessigsäure*, G.

Preparation.—The destructive distillation of wood is effected in sheet-iron cylinders, either upright or horizontal, which may be charged with billets of wood from the top, and from which the charcoal may be removed through a lateral opening. The cylinder is rapidly heated, the resulting volatile products being passed through wide condensing-tubes, cooled by being surrounded with water, into a wooden or iron receiver, from which the condensed products may be drawn off by means of a tap, while the uncondensable gaseous products, consisting of *acetylene* C_2H_2 , *ethylene* C_2H_4 , *propene* C_3H_6 , *marsh gas* CH_4 , and other hydrocarbons, as well as carbonic oxide, are carried off through a pipe into the furnace, there to be burned up in place of other fuel. The condensed portion consists of an aqueous stratum and of an oily or tarry layer containing empyreumatic oils and resins, cresylic and phenylic compounds, various hydrocarbons, etc., and furnishing the material used for the preparation of creasote.

The watery liquid, amounting to about 30 per cent. of the weight of the wood, is the *crude wood vinegar* or *pyroligneous vinegar*, a solution of a large number of products of decomposition, such as small quantities of phenols, guaiacol, and empyreumatic oils and resins, also furfural $\text{C}_5\text{H}_4\text{O}_2$, acetone, methylic and allylic alcohol, methylamine, pyrocatechin, and several acids, the principal one of which is acetic acid, accompanied by formic, propionic, butyric, capronic, crotonic, and other acids. The distillation being carefully conducted, wood yields from 6 to 8, or even 9, per cent. of acetic acid, and wood vinegar, on being evaporated in the water-bath, leaves about 8 per cent. of residue.

On subjecting the crude product to distillation, the first portion (about 10 per cent.) of the distillate contains mainly the alcohols and acetone, and subsequently a colorless or yellowish acid liquid is obtained, amounting to about 75 or 80 per cent. of the crude article. This distillate is *Acetum pyrolignosum rectificatum*, P. G.; *purified pyroligneous* or *wood vinegar*; *Vinaigre de bois*, Fr.; *Holzessig*, G.; and contains variable quantities of most of the constituents of crude wood vinegar, which on exposure to light and the atmosphere cause the distillate to assume a brown color, rendering filtration or redistillation necessary; to avoid this, it should be kept in full and well-corked bottles and in a dark place. The peculiar smoky odor of wood vinegar is due to the presence of empyreumatic products.

Wood vinegar, both crude and rectified, is required by the German Pharmacopœia to contain at least 6 per cent. of acetic acid, so that 10 Gm. of it require for neutralization not less than 10 Ccm. of volumetric solution of potassa. With diluted ferric chloride it usually acquires a dark-green color, due to pyrocatechin. Wood vinegar, particularly that obtained from beech-wood, contains *hydrocærulignone* $C_{16}H_{18}O_6$, a colorless diatomic phenol, which under the influence of oxidizing agents yields *cærulignone* $C_{16}H_{16}O_6$. Liebermann (1872) obtained it from the brown precipitate produced in crude wood vinegar by potassium bichromate, and regards it as identical with Reichenbach's *cedrict*; it forms purplish-blue minute needles, is insoluble in most solvents, but dissolves in strong sulphuric acid with a blue, and in phenol with a red, color, the latter solution yielding with alcohol or ether dark steel-blue needles of cærulignone, and this, by reduction with tin and hydrochloric acid or other agents, is again converted into hydrocærulignone.

A much cleaner pyroligneous acid than by the process described above is obtained by subjecting strips of wood for about 4 hours to the heat of steam under a pressure of from 70 to 100 pounds (150° to 162° C. = 300° to 330° F.), whereby the texture of the wood is but little altered, and the subsequent purification of the acid is simplified. On rectifying the crude product a heavy oil is separated, in which Heill (1877) found furfural, pyromucic acid, a yellow body yielding, with caustic soda, pyroxanthin and other products.

By fractional distillation the volatile impurities of pyroligneous acetic acid cannot be removed, nor can they be readily destroyed by chlorine or other oxidizing agents. To attain this end milk of lime is added in excess, partly for the purpose of forming calcium acetate, partly with the view of removing various tarry products, as insoluble calcium compounds. The solution of calcium acetate freed from the precipitate is evaporated to dryness; the crude salt thus obtained, which contains from 74 to 75 per cent. of hydrogen acetate, is carefully heated upon an iron plate in thin layers until it chars, then redissolved in water, the solution decomposed by sulphuric acid, or preferably by hydrochloric acid, and then distilled. Owing to the difficulty of regulating the heat so as to avoid the destruction of the calcium acetate, the solution of this salt is usually decomposed by sulphate of sodium, the resulting gypsum removed by settling and filtration, and the filtrate evaporated to dryness. The sodium acetate is more manageable in regard to the regulation of the temperature (about 260° C. = 500° F.) necessary to destroy the empyreumatic compounds without affecting the acetate. The latter is purified by dissolving it in a little water, and decanting from the sediment; sulphuric acid is added, the liquid separated from the crystals of sodium sulphate and distilled, when an acetic acid will be obtained more or less pure in accordance with the care exercised in the process of purification.

II. Acidum aceticum glaciale, U. S., Br.; *Acidum aceticum s. Acidum aceticum concentratum s. Acetum glaciale*, P. G.; *Glacial acetic acid*, E.; *Acide acétique concentrée*, esprit de vinaigre, vinaigre glacial, Fr.; *Essigsäure*, Eisessig, G.

Preparation.—Carefully heat $13\frac{1}{2}$ parts of pure crystallized acetate of sodium until the water of crystallization has been completely expelled and the salt has been fused; the residue, weighing nearly 8½ parts, is coarsely powdered, introduced into a glass retort, intimately mixed with 9½ to 10 parts of concentrated sulphuric acid, and then distilled. It is advisable to warm the retort, by placing it in a sand-bath, before the acid is added. The condensation of the acetic acid vapors may be effected either by a Liebig's condenser, or in a receiver connected directly with the retort, or by means of an adapter.

The reaction is as follows: $NaC_2H_3O_2 + H_2SO_4 = NaHSO_4 + HC_2H_3O_2$. Acid sodium sulphate and acetic acid are formed, the latter distilling over, free from empyreuma if the heat has not been suddenly raised too high, and also free from sulphurous and other acids if the sodium acetate has not been contaminated with organic or other impurities. Although, theoretically, the hydrogen acetate or so-called monohydrated acid should be obtained, the product always contains some water, but crystallizes readily near the freezing-point of water. By partial crystallization, pouring off the liquid portion, and repeating this operation, an acid nearly free from water will be obtained. Hydrogen acetate is prepared, according to Hirsch (1873), by intimately mixing 12 parts of exsiccated sodium acetate with 20 parts of fused acid potassium sulphate, and with a carefully regulated heat distilling 7 parts.

Properties.—Glacial acetic acid forms colorless, flat, rhombic crystals, which melt on the application of heat to a colorless liquid, and this retains the fluid condition frequently on being cooled to 10° C. (74° F.), unless brought in contact with a crystal. At the mean temperature of the air it forms a colorless liquid with a pungent acetous odor. When heated to boiling, the vapor may be ignited and burns with a blue flame. Hydrogen acetate fuses at 22.5° C. (72.5° F., Mollerat); has at 16° C. (60.8° F.) a specific

gravity of 1.0553, and boils at 119° C. (246.2° F., Sébille-Auger), or, according to Oudemans, between 117° and 118.2° C.

Rüdorff (1870) gives the congealing point of hydrogen acetate at 16.7° C. (62° F.), and if 100 parts of this acid are mixed with water, the congealing-point will be as follows:

With water,	0.5	1.0	1.5	2.0	3	4	5	6	7	8	9	10 parts.
Congeeing part,	15.65°	14.8°	14.0°	13.25°	11.95°	10.5°	9.4°	8.2°	7.1°	6.25°	5.3°	4.3° C.

The *U. S.* and *Br.* Pharmacopœias require glacial acetic acid to contain 99 per cent. of $C_2H_3O_2 = 84$ per cent. $(C_2H_3O)_2O$; but the melting-point is given at about 15° C. (59° F.) *U. S.*, and 9° C. (48.2° F.) *Br.*, and the specific gravity at 1.056–1.058 *U. S.*, 1.064 *P. G.*, 1.065–1.066 *Br.* An acid of the strength indicated dissolves an equal weight of fresh oil of lemon, but less of the resinified oil. The oil is also far less soluble in weaker acetic acid, requiring about 10 parts of the latter if of 96 per cent. A more reliable test for the absence of water is carbon bisulphide; equal parts of it and glacial acetic acid form, according to Flückiger, a clear solution at and above 20° C. (68° F.), but an opalescent or turbid liquid below that temperature. On neutralizing the acid, 3 Gm. of it require not less than 49.5 Ccm. of the volumetric solution of soda (*U. S.*), or 60 grains of the former 990 grain-measures of the latter (*Br.*); 1 Gm. of the acid requires 16 Ccm. of volumetric solution of potassa (96 per cent. acetic acid, *P. G.*).

Glacial acetic acid absorbs moisture from the atmosphere, whereby its melting-point is lowered and its density increased to a certain degree (see below). For the detection of impurities and adulterations this acid is to be diluted with distilled water previous to testing it as stated below.

Pharmaceutical Uses.—ACIDUM ACETICUM AROMATICUM; Aromatic acetic acid, *E.*; Acide acétique aromatisé, Vinaigre anglais, *Fr.*; Gewürzhafte Essigsäure, *G.* Oil of cloves 9 parts, oil of lavender 6 parts, oil of lemon 6 parts, oil of bergamot 3 parts, oil of thyme 3 parts, oil of cinnamon 1 part, glacial acetic acid 25 parts; dissolve by agitation.—*P. G.*, 1872. The preparation of the French Codex contains 10 per cent. of camphor and $\frac{1}{2}$ per cent. of volatile oils. Aromatic acetic acid is sometimes designated *aromatic vinegar* (see page 14).

Off. Prep.—Acetum cantharidis, Mistura creasoti, *Br.*

Derivative of Acetic Acid.—ACIDUM CHLOROACETICUM, Chloracetic acid, $C_2H_2ClO_2$; mol. weight 129. When glacial acetic acid is left in contact with dry chlorine gas, monochloracetic acid is produced; but on exposing the mixture to direct sunlight *dichloracetic acid* is formed, or trichloracetic acid if the chlorine be in excess. Besides hydrochloric acid, oxalic acid, carbonic oxide, chloroform, chlorocarbon, and other products may be obtained. According to H. Müller (1864), dichloracetic acid is conveniently prepared by passing dry chlorine gas into a retort, which is connected with a reversed condenser, and in which a mixture of acetic acid, specific gravity 1.065, with 10 per cent. of iodine, is heated to boiling. After several days the liquid is distilled; the distillate obtained below 130° C. (356° F.) consists of acetic acid and iodine; at about 135° C. (362° F.), monochloracetic acid, and above 188° C. (370° F.) dichloracetic acid distils. The latter requires further purification by fractional distillation. It is a colorless liquid of a suffocating odor, having at 15° C. (56° F.) the density of 1.5216, congealing in rhombohedral plates, and boiling at 190.5° (375° F.). It acts as a powerful escharotic, and forms salts, which are mostly readily soluble in water. The mono- and trichloracetic acids possess likewise caustic properties.

III. **Acidum aceticum**, *U. S.*, *Br.*; *Acidum aceticum dilutum s. Acetum concentratum*, *P. G.*; *Acetic acid*, *E.*; *Acide acétique*, *Fr.*; *Verdünnte Essigsäure*, *G.*

Preparation.—10 parts of crystallized acetate of sodium are mixed in a suitable retort with the cool mixture of 4 parts of sulphuric acid and 2 parts of water, and heated until at 112° C. (333.6° F.) a dry, spongy mass remains behind (Mohr, 1873). The distillate is then diluted with distilled water until it has the proper specific gravity. If the addition of water is omitted, a larger amount of sulphuric acid will be necessary; the quantity directed here scarcely exceeds the absolutely necessary 1 equivalent, and the reaction proceeds as follows: $2(NaC_2H_3O_2 \cdot 3H_2O) + H_2SO_4 = 2HC_2H_3O_2 + 6H_2O + Na_2SO_4$. The residue in the retort is neutral sodium sulphate.

Properties.—Acetic acid has the specific gravity 1.048 *U. S.*, 1.044 *Br.*, 1.040 *P. G.* These figures indicate a percentage of hydrogen acetate amounting to 36 *U. S.*, 32 *Br.*, and 29 *G.* For acetic acid of a somewhat greater strength, the determination of its specific gravity does not afford a reliable criterion, since the acid of maximum strength on being mixed with water increases in its relative weight until the percentage is reduced

to about 79, when the maximum density will be reached, which at 0° C. (32° F.) is 1.0397 for acid of 80 to 82 per cent., at 15° C. (59° F.) 1.0748 for acid of 77 to 80 per cent., and at 40° C. (104° F.) 1.0501 for acid of 75 to 77 per cent. hydrogen acetate. An acid of 43 per cent. has, at 15° C., the same specific gravity as one of maximum strength, and between 72 and 85 per cent. the density of acetic acid shows very little variation. The following table, by A. C. Oudemans (1866), gives the percentage of hydrogen acetate and the specific gravity of acetic acid of different strengths at 15° C. (59° F.):

Per ct.	Spec. grav.	Per ct.	Spec. grav.	Per ct.	Spec. grav.	Per ct.	Spec. grav.	Per ct.	Spec. grav.
100	1.0553	80	1.0748	60	1.0685	40	1.0523	20	1.0284
99	1.0580	79	1.0748	59	1.0679	39	1.0513	19	1.0270

81	1.0747	61	1.0691	41	1.0533	21	1.0298	1	1.0007

The strength of the official acid is ascertained by weighing out 100 grains of it, diluting with half an ounce of water, applying a moderate heat, and gradually adding 60 grains of bicarbonate of potassium; after effervescence has ceased, and the carbonic acid has been entirely expelled, the liquid should have a neutral reaction to test-paper, or 6.0 Gm. of the acid are neutralized with volumetric solution of soda, of which exactly 36 Cem. (*U. S.*), 32 Cem. (*Br.*), 30 Cem. (*P. G.*) should be required. The test of the British Pharmacopœia, neutralization of 182 grains of acetic acid by 1000 grain-measures of volumetric solution of soda, indicates 33 per cent. of $C_2H_3O_2$; and that of the German Pharmacopœia, neutralization of 10 Gm. of the acid by 50 Cem. of volumetric solution of potassa, proves a strength of 30 per cent. of the same acid. The use of bicarbonate of potassium for neutralization has the advantage of ready calculation, since three-fifths of its weight in grains necessary for 100 grains of the acid indicates directly the strength; the resulting potassium acetate has a faint alkaline reaction, but the error occasioned thereby, being quite insignificant, does not detract from the practical value of the test, more particularly if alkanet-paper be used in place of litmus-paper for determining the neutrality. Absolute accuracy may also be had by treating 200 grains of the acid with an excess of dry, pure carbonate of calcium, washing out the resulting calcium acetate, drying and weighing the undissolved carbonate; the loss in grains, multiplied by three-fifths, gives directly the percentage strength of $C_2H_3O_2$. If dry carbonate of barium be employed instead of the calcium carbonate, the loss in grains is to be divided by 1.6417 to ascertain the percentage of monohydrated acid.

Tests.—The tests for the purity of vinegar are, with some modifications, also applicable to acetic acid. The transparency of the acid is not disturbed on diluting it with distilled water or alcohol, and on evaporating it in a water-bath no residue should be left (saline impurities). Calcium salts will produce a white precipitate with ammonium oxalate. Iron is best detected by the blue color or precipitate occasioned with potassium ferrocyanide; zinc, by the white precipitate; and other metals, like copper, lead, or tin, by the brown or black color or precipitate formed on the addition of hydrosulphuric acid after previous dilution with water. Empyreumatic products, if present in considerable proportion, may be detected by the odor after the acid has been largely diluted with water or neutralized with an alkali; smaller quantities are indicated by adding a minute quantity of solution of potassium permanganate, the color of which will readily disappear; pure acetic acid, containing less than 50 per cent. of hydrogen acetate, is not

affected by this test (Hager, Merck, 1873). Sulphuric and hydrochloric acids are detected in the diluted acid by the white precipitates occurring with barium chloride and silver nitrate respectively. If sulphurous acid be present, the hydrogen evolved by hydrochloric acid and zinc in the presence of the acetic acid will be contaminated with sulphuretted hydrogen, which will darken the color of white bibulous paper wetted with solution of subacetate of lead and suspended in the test-tube or flask; the same acid will also discharge the color of potassium permanganate, and, like the empyreumatic products, cause a dark color and precipitate with silver nitrate. In the presence of nitric acid the liquid will assume an orange-red color on dissolving a little brucine in it, and a dark-brown color on adding first strong sulphuric acid, and afterward a crystal of ferrous sulphate.

The salts of acetic acid are, with very few exceptions, readily soluble in water, and their solutions acquire a dark brown-red color with ferric salts, which disappears on the addition of hydrochloric acid. On adding sulphuric acid to an acetate the pungent odor of acetic acid is recognized.

IV. Acidum Aceticum Dilutum, *U. S.*, *Br.*; *Acetum purum s. destillatum*.—*Diluted acetic acid*, *E.*; *Acide acétique diluée*, *Fr.*; *Reiner Essig*, *G.*

Preparation.—Mix Acetic Acid 17 parts (9 fluidounces) and Distilled Water 83 parts (46 fluidounces), *U. S.*; Acetic Acid 1 pint, and Distilled Water 7 pints, *Br.*

Properties.—Diluted acetic acid has a specific gravity of 1.0083 (1.006 *Br.*), and 100 parts of it neutralize 10 parts ($\frac{1}{10}$ parts, *Br.*) of potassium bicarbonate, or 5.3 parts (3.8 parts, *Br.*) of exsiccated sodium carbonate, indicating a strength of acetic acetate corresponding to 6 per cent. (4.27 per cent., *Br.*) of hydrogen acetate; therefore 10 Gm. of the acid require for neutralization 10 Ccm. (7.12 Ccm., *Br.*) of volumetric solution of soda; or, as the British Pharmacopœia directs, 440 grains of its diluted acetic acid require for neutralization 313 grain-measures of the soda solution, corresponding to 3.63 per cent. anhydride. The purity of diluted acetic acid is ascertained by the same tests mentioned for the stronger acid.

Physiological Action.—When given to animals in large doses acetic acid appears to destroy life by arresting the action of the heart. On examination the stomach is found injected and its mucous membrane softened. Applied to the human skin, it acts as a mild irritant, causing redness and swelling, followed by paleness, of the part, and, if its application is prolonged, it is followed by vesication and desquamation of the cuticle. It first whitens mucous membranes, then turns them brown, causing meanwhile a severe burning pain. Taken internally, it occasions gastric pain, vomiting, and purging, and in rare fatal cases softening of the coats of the stomach and perforation, the pulse meanwhile growing slow and feeble and the skin cool. In a diluted condition it produces no local effects, but when absorbed combines with the alkaline bases in the blood, and is eliminated with the urine and sweat, lowering the pulse in tension and frequency and depressing the temperature. Its continued use may give rise to the changes which are ascribed to its power of impairing the integrity of the blood-corpuscles. It is reported that on being injected into fistulous ulcers it has occasioned death, with symptoms of collapse. It is absorbed by the skin. Foot-baths containing a large proportion of acetic acid have also given rise to symptoms of cardiac and vascular atony, with a marked fall of temperature. When the strong acid was injected into the veins of animals it caused coagulation of their contents, and the same effect has been observed when it was largely administered by the stomach. In these experiments the blood acquired a very dark color.

Medical Uses.—Acetic acid is seldom if ever employed internally, except in the diluted form, which may be used for the same purposes as vinegar, and in the same dose. Strong and glacial acetic acids are applied chiefly as caustics for the removal of *warts* and *corns*, and occasionally for *blistering* the skin. The former is a valuable application in the treatment of *farus*, and, if diluted, allays itching in *lichen*, *prurigo*, and *psoriasis*. It was alleged to possess peculiar advantages as a caustic in *cancer* when injected into the substance of the tumor. But the results of this method are satisfactory only in cases in which, from the situation of the tumor or the objections of the patient, an operation is inadvisable. A solution employed by Gies (1877) varied in strength from

1 part in 3 to 1 part in 9 of glacial acetic acid in water. *Nasal polypus* is reported to be readily curable by injections of pure acetic acid into its substance. The growth shrivels and decays, and its fetor may be corrected by a weak carbolic acid solution (Caro, *Med. Record*, xvi. 526).

Chloroacetic acid has been compared with nitric acid in its action. It penetrates deeply, but does not excite much inflammation of the adjacent parts, and leaves behind a moderate eschar, which soon separates and exposes healthy granulations. The scar is rather smooth, and does not contract a great deal. It is said to cause less pain than nitrate of silver, chloride of zinc, or caustic potassa. It has been used for removing *warts*, *condylomata*, *lupus*, and other neoplasms. It may be applied by means of a glass rod or an asbestos brush.

ACIDUM ARSENIOSUM, U. S., Br.—ARSENIOS ACID.

Acidum arsenicosum (P. G.), *Arsenicum album*.—*Arsenic*, *White arsenic*, *Arsenious anhydride*, E.; *Acide arsénique*, *Arsenic blanc*, *Fleurs d'arsenic*, Fr.; *Arsenige Säure*, *Weisser Arsenik*, G.

Formula As_2O_3 . Molecular weight 197.8.

Preparation.—Arsenious acid appears to have been known since about the beginning of the Christian era, but was first distinguished from other arsenical compounds by Geber in the eighth century. It has been found in many mineral waters in minute proportion, and is obtained in large quantities as a by-product in roasting cobalt, nickel, tin, and even some silver ores, and particularly arsenical iron pyrites; the vapors are conducted through long tubes or chambers, where they are condensed in the form of a white powder, formerly called *flowers of arsenic*. This is not pure, but contains some metallic arsenic, sulphide of arsenic, dirt, etc., from which it is purified by resublimation. For this purpose the crude powder is introduced into cast-iron kettles, surmounted by several communicating iron cylinders, from the top of which a large pipe leads into a series of chambers, where the vapors, which are not condensed in the cylinders, are recovered again as a white powder. The heat, which is applied directly to the kettle, is sufficient to keep the condensing product in the heads or in the first chamber in a soft condition, so that on cooling it congeals into masses. That consumed in this country is mostly imported from Europe; the average annual importation is about 2,500,000 pounds.

Properties.—Arsenious acid occurs in heavy, inodorous masses, which are at first glass-like, transparent, and of a conchoidal fracture, but become superficially white, opaque, and of a waxy lustre, the change penetrating gradually to the interior, so that ultimately the entire mass is converted into a porcelain-like mass, the formation of which is dependent upon a molecular change, the amorphous glass-like arsenious acid becoming indistinctly crystalline. The specific gravity of the vitreous acid is 3.7385, and of the opaque variety 3.699 (Guibourt). Durand and Mitchell determined (1832) the density of the former to be about 3.3. When heated in a sealed tube arsenious acid may be melted to a thick liquid, and again be obtained as a glass-like mass, or, when very slowly cooled, in crystals of different form. Rapidly heated in an open test-tube, it begins to soften superficially at about 218° C. (424° F.), but is at the same time rapidly volatilized. Slowly heated in a glass tube to about 200° C. (392° F.), minute transparent crystals are obtained, which under a magnifying-glass are recognized as regular octahedra. It is dimorphous, crystallizing also in thin pearly prisms, which are sometimes obtained in the process of roasting arsenical ores. When thrown upon burning charcoal, it is reduced to the metallic state and vaporized, arsenious acid being again produced and an alliaceous odor emitted. It does not readily mix with water, and has a scarcely perceptible, faintly sweetish taste, due to its slow and sparing solubility in water; but this solution has a slight but distinct metallic taste and a feeble acid reaction, and unless acidulated with a mineral acid is not completely precipitated by hydrogen sulphide, but remains yellow and transparent, or in reflected light slightly turbid from dissolved As_2S_3 . The crystalline acid is less soluble than the amorphous, but one is under various circumstances converted into the other. By prolonged contact with cold water about $\frac{1}{4}$ per cent., and by boiling water about 7 per cent., of the acid is dissolved, but after boiling for several hours about 11 per cent. is taken up, the greatest portion crystallizing on cooling, leaving about $2\frac{1}{2}$ per cent. in the solution; and on prolonged standing this amount is reduced to somewhat less than 2 per cent. The acid does not volatilize with the vapors of boiling water. Bussy found (1847) that 100 parts of water of 13° C. (55.4° F.) will dissolve 4 parts of amorphous and 1.2 parts of crystalline arsenious acid, the former solution gradually depositing crystals until

reduced in strength to the latter. Treated with warm or cold ammonia-water, the amorphous acid is converted into the crystalline variety without combining with the ammonia (Guibourt). Solutions of both the amorphous and crystalline variety pass readily through the septum of the dialysator. By the aid of heat glycerin dissolves arsenious acid slowly but freely, and deposits again a portion of it on dilution with water. Arsenious acid is insoluble in ether, quite sparingly soluble in alcohol, but combines with fixed oils when heated, forming a plaster-like mass; several acids increase its solubility in water, particularly hydrochloric and tartaric acids.

Powdered arsenious acid is often adulterated; hence it should not be employed for medicinal purposes unless its purity has been previously established. When rubbing the hard masses of vitreous or porcelain-like acid to powder, sufficient alcohol should be sprinkled over it to prevent the dust from rising, and the mouth and nostrils should be protected by a moist sponge. When larger quantities are powdered, it is even advisable to protect the eyes and the bare hands.

Tests.—Arsenious acid is completely volatilized without fusion at a temperature of 2045°C . (4000°F .), and yields a white sublimate free from gray or orange-colored portions (absence of metallic arsenic and sulphides). By prolonged boiling with diluted hydrochloric acid, it dissolves completely without leaving any residue, and 100 grains of it, thus dissolved, yield with hydrosulphuric acid a deposit of tersulphide of arsenic weighing, after washing and drying, 124 grains. 4 grains of it, dissolved in boiling water with 8 grains of bicarbonate of sodium, discharge the color of 808 grain-measures of the volumetric solution of iodine.—*Br.* Both the tests mentioned prove arsenious acid to be almost absolutely free from impurities; but the U. S. Pharmacopœia of 1880 admits this compound if containing not less than 97 per cent. of the pure anhydride; in which case .247 Gm. of it, dissolved in boiling water with .5 Gm. of sodium bicarbonate, will decolorize not less than 48.5 Cem. of the volumetric solution of iodine; if pure, 49.95 Cem. of the latter would be required. The reaction occurring in this test is shown by the equation: $\text{As}_2\text{O}_3 + 5\text{H}_2\text{O} + 2\text{I}_2 = 2\text{H}_3\text{AsO}_4 + 4\text{HI}$; 1 molecular weight of arsenious acid is oxidized by 4 atomic weights of iodine, with the formation of 2 molecules of arsenic and 4 of hydriodic acid. The admixture of arsenic acid is detected by agitating an excess of the powder with cold alcohol, filtering, evaporating, and neutralizing with ammonia, when silver nitrate will produce a red-brown precipitate.

Pharmaceutical Uses.—*PULVIS ARSENICALIS COSMI.*—Côme's arsenical powder, *E.*; Poudre caustique du frère Côme, *Fr.*; Cosmiches Pulver, *G.* An intimate mixture of vermilion 5 parts, arsenious acid 1 part, and burned sponge 2 parts.—*F. Cod.* The French Codex recognizes also a weak arsenical powder, containing one-twenty-fifth its weight of arsenious acid, and known as *poudre escharotique d'Antoine Dubois*.

Off. Prep.—Liquor arsenicalis (potass. arsenitis). Liq. acidi arseniosi (arsenici hydrochloricus), Sod. arsenias, *U. S.*, *Br.*

Detection of Arsenic and Arsenious Acid.—A neutral or, more promptly, an acidulated solution of arsenic yields with sulphuretted hydrogen a bright-yellow precipitate of *sulphide of arsenic*, which is entirely insoluble in dilute acids, but dissolves readily in alkalis, their carbonates and sulphides; if such a solution in sulphydrate of ammonium is acted upon by nitrate of silver in excess, sulphide of silver is precipitated, and the solution contains the arsenic in its original state of oxidation, either as arsenious or arsenic acid, and on the careful neutralization of the ammonia by means of nitric acid, the former is precipitated as yellow arsenite of silver, and the latter as red-brown arseniate of silver, both precipitates being readily soluble in nitric acid and in ammonia. Neutral solutions of arsenious and arsenic acids yield with sulphate of copper precipitates, that of the former being yellowish-green (*Scheele's green*), and of the latter bluish-green, in color; both precipitates are freely soluble in nitric acid and in ammonia. It follows, from the behavior just described, that in testing by a soluble silver or copper salt for arsenious or arsenic acid, the solutions of the latter must be very carefully neutralized, or, if acid, are best tested with ammoniacal solutions of copper and silver; but the complete precipitation of arsenic is most conveniently effected from an acidulated solution by means of sulphuretted hydrogen gas; if strongly acid, the liquid should be diluted with water, and it is in all cases advisable, after adding an excess of the gas, to set the mixture aside for some time, if little arsenic is present, even for 24 hours. If not mixed with other metals, the precipitate thus obtained is pretty characteristic, since only two other metals yield under the same circumstances precipitates of sulphides having a similar color—namely, *cadmium* and *tin* in *stannic* compounds. *Cadmium sulphide* has a bright lemon-yellow

color, but is readily distinguished from the corresponding arsenic compound by being completely insoluble in potassa, ammonia, and sulphhydrate of ammonium; on the other hand, cadmium sulphide

FIG. 1.

Reduction-tube of Berzelius.

FIG. 2.

Reduction-tube with sublimate of arsenious acid.

dissolves completely in strong hydrochloric acid, forming cadmium chloride, and giving off sulphuretted hydrogen, while sulphide of arsenic is insoluble in the acid mentioned. *Stannic sulphide* has a dusky-yellow color, and dissolves in potassa, ammonia, and sulphhydrate of ammonium, but differs from sulphide of arsenic not only in the shade of color, but also in its complete solubility in strong hydrochloric acid. The three sulphides may likewise be distinguished from each other by their behavior with *cyanide flux*, which is an intimate mixture of 1 part of cyanide of potassium with 3 parts of anhydrous sodium carbonate; when heated with this flux in the bulb of a Berzelius reduction-tube, sulphide of arsenic yields, in the cooler part of the tube, a sublimate of metallic arsenic having an iron-gray color, and in the upper portion of the ring occa-

FIG. 3.

Sublimate of arsenious acid, magnified.

sionally a brown color, produced by the intimate mixture of metallic arsenic with some arsenious acid; during the sublimation a garlic-like odor is observed; the sublimate volatilizes on the application of heat, and condenses again in a cooler part of the tube, and, if atmospheric air has been admitted, is partly or entirely converted into minute brilliant octahedral crystals of arsenious acid. Sulphide of cadmium, under the same circumstances, yields a red-brown sublimate, consisting of oxide of cadmium, which is not volatilized by heat; and sulphide of tin produces no sublimate; but in the fused mass will be found metallic grains of tin.

The above tests characterize arsenic if in the form of solution and if present in more than a very minute quantity. Tests of still greater delicacy will be described below. Arsenious acid, which is usually met with in cases of accidental or criminal poisoning, yields, if heated in a narrow tube, the crystalline sublimate described above; and if mixed with charcoal or cyanide flux, the sublimate will, as in the above case, consist of metallic arsenic, and this, on being sublimed in the presence of air, will yield the same crystals.

In the presence of much organic matter the detection of arsenic is a more complicated process, involving the separation of most of the organic matter; which Fresenius and Babo (1844) have accomplished by heating the mass in a water-bath with hydrochloric acid, and adding to it chlorate of potassium in small quantities until a thin liquid is produced; if the heat be not raised beyond the temperature of boiling water no chloride of arsenic will be volatilized, but the mixture becomes more liquid in proportion as the solid organic substances are destroyed. The liquid is then filtered, the clear filtrate saturated with sulphuretted hydrogen, and the precipitate, which contains organic matter, treated with strong nitric acid, and subsequently fused with pure nitrate of sodium, whereby the organic compounds are completely destroyed, and the antimony and arsenic are converted into soluble arseniate and insoluble antimoniate of sodium. On mixing this residue intimately with about twelve times its weight of an exsiccated mixture prepared of sodium carbonate 3 parts and potassium cyanide 1 part, the powder may be heated to redness in a reducing-tube in a current of dry carbonic acid gas, when a mirror of metallic arsenic will be obtained, while the presence of antimony, tin, and other metals will not interfere with the result. This method is less delicate than others mentioned below; however, the mass

obtained after the destruction of the organic matter and fusion with sodium nitrate may be dissolved in water, and this solution, after acidulation with hydrochloric acid, may then be treated again with sulphuretted hydrogen, or in Marsh's apparatus—in the latter case, after evaporation with an excess of sulphuric acid to expel the nitric acid.

The destruction of the organic matter, as described above, may in some cases be omitted, the material being simply boiled with water and the filtrate acidulated with hydrochloric acid, previous to passing sulphuretted hydrogen through it. A solution suitable for the purpose may likewise be obtained by the process of dialysis, whereby mucous, amylaceous, and albuminous substances are left behind, while the dialyzed liquid contains the arsenious acid, besides organic and inorganic salts. A method for converting arsenious acid and sulphides of arsenic into the volatile chloride, which may be readily separated from the organic matter by distillation, was proposed by F. C. Schneider (1851); it consists in mixing the material with large crystals of sodium chloride equal in weight to the dry matter, adding concentrated sulphuric acid and heating slowly to boiling. To avoid the generation of sulphurous acid, an excess of sodium chloride must be present during the entire operation. A modification of this process, whereby the sulphides are more readily decomposed and arsenic acid is reduced to arsenious acid, and then readily converted into chloride, consists, according to Hager, in the addition of ferrous chloride to the contents of the retort. Dr. Penny (1852) suggested the thorough drying of the material, mixing it with strong hydrochloric acid, and then heating in a retort placed in a sand-bath. Dr. A. S. Taylor observed that portions of dried liver or stomach gave up every trace of arsenic by one distillation. The distillate may be tested for arsenic by the reagents mentioned above, or in Marsh's apparatus.

Marsh's test depends upon the formation of arseniuretted hydrogen (hydride of arsenic) by the action of nascent hydrogen upon the oxygen compounds of arsenic. A simple form of Marsh's apparatus is

shown in Fig. 4. Hydrogen is generated in a suitable flask, and dried by conducting it through a tube, *a*, filled with fragments of calcium chloride. After the air has been completely expelled, and the apparatus filled with hydrogen, some of the liquid to be tested is introduced through the funnel-tube, and the escaping gas ignited at *b*. Upon holding a piece of porcelain in the flame, a brown-black spot of metallic arsenic will be deposited, which

Marsh's test for arsenic.

will quickly dissolve on the addition of a little chlorinated lime or chlorinated soda (Bischoff, 1840). Antimony compounds will yield a similar spot, which, however, is not affected by the hypochlorites. When a dry beaker, *c*, is held over the jet, arsenious acid is deposited upon the inside, and may be recognized by its crystalline form; and, after dissolving it in a little hot water, a yellow precipitate will be obtained on the addition of some solution of ammonio-nitrate of silver. Antimony similarly treated gives no precipitate. The delivery-tube, which must be of hard glass, may be heated to redness by the flame of a gas-lamp, *d*, when the hydride of arsenic will be decomposed, metallic arsenic being deposited. Antimony gives a similar reaction, and the two metals may be distinguished by heating the deposit in contact with air, when the arsenic will be converted into crystallized arsenious acid; or sulphuretted hydrogen may be passed through the tube and the deposit gently heated, when the arsenic will be converted into yellow sulphide and the antimony into orange sulphide. On now passing dry hydrochloric acid through the tube the sulphide of antimony will disappear and the sulphide of arsenic remain unaffected.

On passing the hydrogen gas from the delivery-tube, through acetate of lead to remove any H_2S , into a solution of nitrate of silver, a black precipitate will be produced both by antimony and arsenic. If the former, the deposit will consist of a compound of antimony and silver; if the latter, metallic silver only is precipitated, while the solution contains the arsenic as arsenious acid mixed with the excess of silver salt, and on cautiously neutralizing with ammonia a yellow precipitate of arsenite of silver is obtained.

Bettendorff's Test (1869).—On adding some arsenical solution to a solution of stannous

chloride in strong hydrochloric acid, a gradual, or, on heating, a somewhat rapid, reduction to metallic arsenic takes place, the deposit having a brown or black color according to quantity. Dilution with water and the presence of nitric acid or nitrates interfere with the reaction.

Reinsch's Test (1843).—If an arsenical solution is strongly acidulated with hydrochloric acid, and heated to boiling in the presence of a thin slip of bright copper—or, according to A. S. Taylor, preferably of finest copper gauze—the copper will become tarnished by the deposition upon it of metallic arsenic, the film having a bluish or iron-gray color according to quantity; the presence of nitric acid interferes with the reaction. The copper is washed with water, dried, and heated in a narrow test- or reduction-tube, when arsenious acid will be sublimed in the form of octahedral crystals.

Fleitmann's test, like the process of Marsh with its numerous modifications, depends upon the generation of arseniuretted hydrogen from zinc; instead of an acid, however, a strong solution of caustic potassa or soda is employed, which has the advantage of preventing the formation of antimoniuiretted hydrogen. If the gas is generated in a test-tube, the orifice of which is covered with a piece of filtering-paper moistened with a solution of nitrate of silver, the appearance of a black spot will indicate the presence of arsenic. In applying this test care must be taken to prevent the paper from coming into contact with the alkaline liquid, which would produce a similar color. A plug of cotton loosely inserted in the upper part of the tube will prevent any spirting of the liquid. A strip of paper moistened with solution of lead acetate, if colored brown or black by the gas, would prove the presence of sulphuretted hydrogen.

This process has been modified in various ways. Himmelmann (1868) proposed to generate the gas with a mixture of granulated zinc and powdered iron, which is warmed in a concentrated solution of ammonium chloride rendered alkaline by ammonia. The gas is passed through a solution of zinc and ammonium chlorides into the silver solution. Johnson proposed aluminium in connection with potassa solution for the generation of hydrogen. In this as in the preceding case the metals employed are to be previously tested for the presence of arsenic.

Much simpler is the modification by E. W. Davy (1876), who employs an amalgam prepared by warming 8 or 10 parts of mercury, and dropping upon it gradually in small pieces 1 part of metallic sodium. The amalgam should be used only in a neutral or alkaline liquid; the gas is generated by the action of the sodium upon water, and the presence of arsenic in it is recognized with nitrate of silver, as stated above.

Precautions.—It is scarcely necessary to remark that when testing for arsenic all the reagents must be absolutely free from that metal. The purity of sulphuric and hydrochloric acids is most conveniently ascertained by Bettendorff's or Reinsch's process, and the purity of zinc by that of Fleitmann. The use of copper for the purpose referred to is not, as a rule, interfered with by its containing arsenic, but the presence of the latter may be readily detected, according to Odling (1863), by heating it in a retort with six times its weight of ferric chloride and an excess of hydrochloric acid, when chloride of arsenic will distil over and give the usual reactions of arsenic compounds.

In forensic analysis it is usually required that the arsenic be separated in the metallic state, and that the quantity of the poison be estimated. The former is accomplished by the methods described above; the latter, by weighing the metal deposited in the heated delivery-tube of Marsh's apparatus, either upon the glass or upon platinum introduced for the purpose, or by estimating it in the form of pyroarsenate of magnesium.

Physiological Action.—Arsenic is hostile to all forms of vegetable life, whether it acts upon the foliage of plants through the air or through their juices by absorption from the soil. It tends to shrivel the leaves and other soft structures if the supply of water is small, or to rot them if the soil and air are moist. It speedily destroys the life of insects and fishes, occasioning convulsive movements in the latter. In birds, however introduced into the system, it produces symptoms of gastro-intestinal irritation, as well as nervous depression, exhibited by debility, spasm, or paralysis. In quadrupeds the same evidences of gastro-intestinal irritation and nervous prostration or irritability predominate. But to produce such effects the quantity of the poison introduced at once into the system must be large. After slow poisoning the digestive organs do not usually present the ordinary evidences of inflammation, although they may exhibit an unusual amount of mucous secretion, containing more or less fibrin. The mineral may be detected in the milk of nursing women using it, and in all the organs, but chiefly in the liver and spleen, of animals poisoned by its use. A very curious effect observed by Gies in animals is that continued, small, non-irritant doses of it produce a very marked augmentation in the

growth of the bones, which become thicker and denser. At the same time, however, the liver undergoes fatty degeneration, and the heart likewise, but in a less degree. Indeed, according to some experimenters (Saikowsky; Livon), the same lesion exists, more or less, in all the organs. If, however, the dose exceeds a certain minimum quantity, chronic poisoning ensues, with symptoms like those described below as occurring in man—viz.: emaciation, loss of hair, gastric catarrh, diarrhœa, impaired sensibility, and paralysis of the legs.

The application of arsenical preparations to the surface of the body is often followed by symptoms of poisoning, particularly if the integument is not whole, as where they are employed in the topical treatment of skin diseases. But such effects are sometimes observed even when the skin is sound, as when an arsenical solution has been used to destroy vermin upon the head and other hairy parts, or when for any purpose it has been allowed to remain too long applied.

In these cases also gastro-intestinal symptoms predominate, together with thirst, difficult deglutition, pain in the head, and sometimes micturition. Still more severe symptoms are promptly induced by the prolonged contact of arsenic with the vagina and with the surface of wounds and ulcers, including ulcers from cancer treated by arsenical caustics. Poisoning also results from the inhalation of arsenical vapors given off during the combustion of this mineral, from the fine dust produced during its manufacture, and by that of compounds into which it enters. Of these the most prolific in mischief are arsenite of copper, or Scheele's green, and Schweinfurth green, which are extensively used as pigments for paper-hangings, artificial flowers, and even dress goods. Other colors used in the arts besides green contain arsenic; it has been found in blue, red, and yellow papers. The symptoms produced in this manner include irritation of the eyes, sore mouth, dyspepsia, neuralgia, spasm, paralysis, cutaneous eruptions, and progressive emaciation.

It is certain that when arsenic is taken habitually, commencing with very small doses, a certain tolerance of its action is induced, so that quantities may at last be consumed which at first would have been actively or fatally poisonous. This remarkable fact has been largely illustrated by the arsenic-eaters of Styria, who employ the drug for the purpose of maintaining a ruddy complexion and enabling them to climb without panting the steep mountain-paths of their country. Their acquired tolerance of it is such that some of them have been known to take 5 or 6 grains of arsenious acid without the slightest inconvenience. Similar tolerance has been observed in isolated cases elsewhere, and in certain experiments of Flandin animals that began with the daily dose of $\frac{1}{6}$ of a grain were able at the end of 9 months to take upward of 15 grains of arsenious acid in powder mixed with their food in the course of 24 hours, without injury to their appetite or health. To the same purpose is the statement of Hebra that in the treatment of psoriasis he sometimes raised the daily quantity to nearly a grain of arsenious acid (gr. 0.99), and continued the dose for many months. "In this way," he adds, "it has several times occurred that the patient has taken the enormous quantity of more than 160 grains of arsenious acid before he got rid of the disease. . . . In no instance did I see any ill effects produced" (*Dis. of the Skin*, Syden. Soc. ed., ii. 29). If we seek a reason for at least the former of these effects, it may be found, theoretically, in the power which arsenic has of diminishing oxidation, and therefore the need of oxygen in the system, and also of causing a paralysis of the vaso-motor nerves. But evidently this explanation will not apply to those cases—the most numerous indeed—in which, so far from producing the fatty degeneration spoken of above, the habitual use of arsenic does not impair, but improves, the health. Possibly the explanation may be found in the rapid oxidation which the active life of the Styrian mountaineers secures, and which is checked and reduced to a due degree by the opposite and, as it were, antidotal action of arsenic.

When arsenic is taken in small doses, as from 3 to 5 drops of solution of arsenite of potassium, and after meals, it may be used for some time without occasioning any local symptoms; but if the dose be too large it is apt to cause loss of appetite, nausea, abdominal pain, and vomiting or purging. A metallic taste may also be perceived in the mouth, the eyes grow red, and œdema of the eyelids takes place, which, if the medicine is continued, may extend to the whole body. The urine may also become albuminous or even bloody. A longer continuance of the medicine is apt to occasion affections of the skin, particularly itching, urticaria, pityriasis, psoriasis, desquamation of the cuticle, and shedding of the nails. Sometimes the hair falls out. If the medicine is continued in the same or in greater doses, signs of irritation arise in the œsophagus and stomach, with vomiting and

diarrhœa; the nervous system becomes disturbed; tremor, convulsion, muscular rigidity, and paralysis have followed acute and also chronic arsenical poisoning; the paralyses are nearly always peripheral; the pulse is irregular; there is a complete loss of appetite, with a silvery coating of the tongue, salivation, thirst, tenesmus, and colic; the respiration grows oppressed, the flesh wastes, and the limbs are the seat of severe pains. These phenomena are most frequently observed in workmen employed in the sublimation of arsenical ores; and among them it is not unusual to see numbness and contraction of the extensor muscles of the lower limbs, with torpor of the mind, and a general cachectic, emaciated appearance, with pustules and ulcers of the skin. According to the experiments of Cutler and Bradford (1878), solution of arsenite of potassium given in health causes a progressive decrease in the number of the red and white blood-corpuscles, that of the latter being the most marked. In simple anæmia, on the contrary, there seems to be an increase at first of both the red and white corpuscles. After a certain point there is a steady diminution of both. In a case of leucocythemia there was also a decrease of both, that of the white corpuscles being very marked. In a case of "idiopathic anæmia" Dr. Edes found that under very moderate doses of arsenic the number of red corpuscles increased nearly fourfold in the course of one month (*Boston M. & S. Jour.*, Oct. 1880, p. 392), and in four cases of "pseudo-leukæmia" Warfynge, without specifying the precise increase in the hamatin of the blood, noted the improved general condition and the subsidence of the glandular swellings while arsenic was administered (*Med. News*, etc., June, 1881, p. 342).

The symptoms of acute arsenical poisoning are the following: constriction and heat of the fauces, burning pain in the stomach and bowels, violent retching and vomiting, with spasms of the throat; insatiable thirst, a dry tongue, bloody stools and strangury, muscular spasms, oppressed breathing, irregular pulse, paleness and coldness of the skin, and general collapse. When death does not result the cure is generally slow and sometimes imperfect; digestion remains impaired, the muscles are stiff and feeble, and sometimes they are more or less paralyzed, especially those of the lower limbs. After death from acute arsenical poisoning the gastro-intestinal mucous membrane is usually found inflamed, softened, and sometimes, when the poison has been taken as a powder, covered with a false membrane; but in other cases, those in which nervous prostration has predominated, the gastric lesions may be quite inconsiderable. The violence of the symptoms and the subsequent lesions are apt to be greatly modified by the presence of food in the stomach when the poison is swallowed, and hence the fatal dose varies between remote extremes. The spinal and nervous symptoms are to be explained, according to Popow (*Virchow's Archiv*, xciii. 351), by a myelitis involving both the gray and the white elements of the cord.

The curative operation of arsenic cannot be explained by the effects of directly poisonous doses. The explanation must be sought in the nature of those changes in the blood, nervous system, and general nutrition occurring in chronic poisoning, and especially in the dropsical effusions and the alterations in the skin and its products which are so commonly observed. They point directly to changes in the blood by which the proportion of its solid elements is diminished, and the facility of elimination of its morbid constituents is increased. That this elimination takes place through the kidneys is not improbable, since the mineral itself is chiefly discharged through those channels, and the proportion of the urea in the urine is augmented. But such phenomena are still to a certain extent morbid, and they are not usually developed by the therapeutical operation of the medicine. Indeed, the occurrence of dropsy in the form of œdema of the eyelids is generally held to be a signal for suspending the use of the medicine or for diminishing its dose. Within these limits arsenic appears to act as a tonic, improving the digestion and nutrition, restricting the excretion of tissue in the forms of carbonic acid and urea, and lowering the temperature. It would seem, then, that, according to its dose, it may act as a conservative tonic or as an eliminative agent; and this interpretation would appear to reconcile its apparently opposite effects. Thus, comparatively small doses suffice to cure neuralgia and certain cases of intermittent fever, while comparatively larger doses are required by chronic malarial affections and diseases of the skin.

In this sketch of the probable operation of arsenic a subordinate place is given to its direct action upon the nervous system. But there is much reason for thinking that as, physiologically, the supply of blood in the tissues, and the molecular action of the latter, must be under the control of the nervous system, so many of the effects of arsenic may be plausibly ascribed to a primary and direct action upon that system. It is well known that numerous cases of acute skin disease (herpes, urticaria, lichen) arise under the direct

influence of mental causes, and are some of them closely related in their distribution to that of the nerves. Again, the symmetrical eruption of the patches in scaly affections appears to demonstrate a nervous influence in the derangement, for such symmetry from a mere alteration of the blood is less conceivable. Moreover, the phenomena of chronic arsenical poisoning are, as already stated, presented by the nervous system. Finally, the action of arsenic in curing intermittent fever, like the similar action of quinia, is rendered more intelligible by referring it to the nervous system than in any other manner. Very probably the actions of the medicine upon the blood and upon the nervous system are simultaneous and co-operate with one another.

Numerous experiments upon animals have within the last few years been performed to illustrate the action of arsenic upon certain portions of the nervous system, and especially upon the cardiac ganglia and respiratory centres. But it is difficult to discern any relations between them and the action of arsenic on man in either poisonous, physiological, or therapeutical doses. If they prove anything, it is that this agent impairs the circulatory and respiratory vigor; whereas the very opposite effects are among the most striking as well as the most useful operations of arsenic as a medicine. Nevertheless, since the excessive action of a medicine produces effects the very opposite of those occasioned by its primary medicinal doses, it becomes of interest to know that both in acute and chronic poisoning by arsenic the metal accumulates in the brain and medulla oblongata more than in the liver and muscles. It is especially so since it has been shown by Binz and Schulz (*Arch. f. Exp. Path.*, xi. 219) that in fatal cases of arsenical poisoning death cannot be explained by the gastric lesions, but is apparently due to depression of the functions of the great nervous centres; which, indeed, may amount to complete paralysis.

Medical Uses.—The use of arsenic as a remedy for *intermittent fever* has prevailed in China from time immemorial. As a substitute for the cinchona alkaloids in its treatment it has been extensively resorted to, and the general result of experience is that it is not comparable to the latter medicines in efficacy. The greater number of cases in which it shows a decidedly curative operation are of the chronic form above referred to—cases in which quinia had failed to effect a cure, and in which the malarial cachexia was distinctly marked. In these the cure by arsenic generally coincides with evidences of the constitutional operation of the remedy. In various *skin diseases* arsenic is an invaluable remedy, but is especially so in *lepra*, *psoriasis*, and *chronic eczema*. In a large proportion of cases of these affections it effects a perfect cure; but in none of them can it be regarded in the light of a specific. Some dermatologists advise that the medicine should be given in very small doses at first, and gradually in larger doses, until its constitutional effects are developed; others insist upon commencing at once with a full but moderate dose (5 minims of the solution), and persisting in its use until the injection of the eyes or the swelling of the eyelids appears, when the dose should be gradually reduced until these phenomena subside. In either case the medicine should be continued for some time after the eruption has disappeared. The last point is of essential importance. *Chronic eczema* is less amenable than the dry scaly eruptions to the use of this medicine, but nevertheless will often yield to it alone. By several dermatologists arsenic is pronounced a specific for *pemphigus*, and, although this estimate of its value is too absolute, there is no doubt of the superiority of the medicine to any other in that disease. It must, however, be given perseveringly and for some time after the disappearance of the eruption, and does not dispense with the necessity of using preparations of cinchona and iron and appropriate diet and regimen. Syphilitic eruptions of the skin are not curable by arsenic. Of that most intractable of skin diseases, *prurigo*, arsenic is credited with a cure by Geber. But the patient was young, and other treatment was employed (*Boston Jour.*, Oct. 1880, p. 396). *Lichen ruber*, also a disease which is rarely cured, is stated by Koebner to have been removed by hypodermic injections of from 3 to 6 minims daily of Fowler's solution, diluted with twice as much water. The treatment lasted for 2 months (*Med. News*, etc., May, 1881, p. 292). *Warts*, especially those which appear rapidly in large crops, may generally be cured by arsenic given internally. Enlarged lymphatic glands (*lymphoma*), whether superficial or occupying the great cavities, are singularly amenable to this medicine when the dose is carried to the extent of producing its full constitutional effects and then gradually reduced. When the tumors are accessible their injection with the arsenical solution (Fowler's) has been successfully practised. The operation is apt to produce some febrile reaction, but leads to the absorption of the hyperplasia. It may be mentioned for information, but not as an example to be imitated, that Fowler's solution has been injected into the *enlarged spleen* by means of the hypodermic syringe, and with

alleged success, although in other cases the effects were injurious or even fatal (*Bull. de thér.*, c. 380).

It is reported that several cases of *obesity* have been restored to a normal condition by the continued use of Fowler's solution in the dose of 5 drops three times a day.

This medicine has enjoyed a certain reputation in the treatment of *nodosity of the joints*, both as an internal medicine and under the form of arsenite of sodium in baths. Several distinguished names vouch for its efficacy, but we have made use of it persistently in several cases of the disease without the slightest advantage. In *chorea* it has enjoyed a very high repute, so much so as to have been looked upon by certain physicians as a specific; but, on the other hand, some of the best authorities do not even refer to it among the remedies for the disease. The former judgment is undoubtedly the correct one; but to ensure the efficiency of the medicine it must usually be given so as to induce its constitutional effects as rapidly as possible. Our own impression of its value is very decided in those numerous cases in which chorea occurs, as it so often does in delicate children, from overstrain of the mind or from any other exhausting excitement. Its hypodermic administration, which has been advocated, is not to be commended.

The advantages of arsenic in *neuralgia*, especially of the fifth pair and of the intercostal nerves, the forms which most usually depend upon constitutional or acquired debility, have been recognized ever since they were first pointed out by Fowler. It is true that the cases most readily cured by it are those of miasmatic origin; but whether the disease depends upon miasma as a direct effect, or upon its indirect influence on the constitution of the blood, is not clearly determined. Instances are indeed cited of its effecting the cure of traumatic neuralgia, but they are very rare and open to criticism. Besides the miasmatic forms, there are but few cases of neuralgia which are not benefited, even if not cured, by arsenic. The mode of its action may be inferred also from the well-known fact that facial and intercostal neuralgias are precisely those in which iron is a very efficient remedy. It would appear that large doses of the medicine are sometimes essential to the cure, such as 20 or 30 minims of Fowler's solution at first, and subsequently smaller quantities (Francis). In certain cases sulphate of quinia and the arsenical medicine, each in half of the full dose, have been associated with results that could not be secured by either alone. Another form of the disease, *gastralgia*, very frequently arises under similar states of the system, and is often curable by arsenic; this is the more remarkable, considering how frequently this neuralgia is associated with gastric ulcer, and renders it probable that both affections are cured by the action of arsenic in improving nutrition. This power is conspicuously manifested by it in many cases of pulmonary *phthisis*. Under its influence the bronchial irritation and secretion decline, the hectic abates, the breathing grows calmer, the appetite improves, flesh is gained, and life is prolonged, if not permanently secured. It is not in every case that these effects are witnessed, nor is it possible to determine in what cases they may be looked for. But it would seem that arsenic is most efficient when the bronchitic element is strongest and the degenerative process is least active. This judgment is rendered probable by the manifest benefits derived from the medicine in many cases of chronic *bronchitis* affecting the lower lobes of both lungs. In nearly all of the diseases mentioned in this article more or less impairment of the blood exists, and many of them are more or less curable by iron. Indeed, in all of them the association of iron and arsenic is more efficient than either medicine alone. In no disease is this operation more distinct than in *chlorotic anemia*, an affection in which the nervous as well as the blood element requires a specific treatment. Sulphuret of arsenic was anciently used for asthmatic affections. Many years ago Koepf employed Fowler's solution in *spasmodic asthma*, in which he was imitated by Trousseau, who also prescribed cigarettes made of tissue-paper impregnated with the same solution. Subsequently Thorowgood (1874) stated that this solution is alike useful in dry and in humid asthma, and that if the affection is connected with old chronic skin disease it may be prescribed with every prospect of benefiting the patient. No doubt the medicine is occasionally efficient in pure nervous asthma, but it is more successful in ordinary disease combined with chronic bronchitis and emphysema. To the tonic and reconstituent power of arsenic must be attributed its utility in many cases of *uterine disorder* due to an enfeebled constitution or to more local causes; for it is in *amenorrhœa*, *menorrhœgia*, *dysmenorrhœa*, and *leucorrhœa* that it has been found efficient; and these affections, although very different symptomatically, may have their root in the same organic debility. The utility of the medicine in many cases of *diabetes* may fairly be attributed to a like operation. They are cases in which iron and also strychnia have been found useful—cases in which general debility is attended with a comparatively small

secretion of urine, how high soever its specific gravity may be. Yet there are others which have been materially improved by this medicine, although the diuresis was profuse. In three-drop doses it is represented by Von Pap as greatly diminishing the sugar in the urine in diabetes, sometimes removing it, and in certain cases causing it to disappear for some time after the arsenic had ceased to be given. (Compare Quinquaud, *Bull. de théér.*, ciii. 241.)

In a case of long-continued *albuminuria*, apparently depending upon debility and indigestion, and in which the presence of albumen in the urine was not constant, Dr. Brinton found that small doses of Fowler's solution were more efficient than any other medicine. In the *chronic diarrhœa* of children it is reported to have cured cases that resisted other remedies.

The treatment of *cancer* by arsenic has been both internal and external. At one time the administration of iodide of arsenic was held by competent authorities to be capable of diminishing the size of cancerous tumors, but the treatment has now lost whatever credit it once possessed. As a caustic, arsenic was used for the destruction of cancerous tumors even by the ancients, and throughout the course of medical history examples may be found of faith in its propriety and efficacy. But in recent times the practice has chiefly fallen into the hands of quacks. Superficial cancers, and tumors under various names which tend to occasion ulceration, including *lupus*, continue to be occasionally treated by means of arsenical caustics. Most of them are, however, excessively painful, and if applied over a large surface involve the risk of producing poisonous effects. Es-march, in the treatment of desperate cases too far advanced for the use of the knife, employed arsenic both internally and externally, the former because the medicine is supposed to promote the disintegration of albuminous compounds; and for the latter purpose he applied a powder composed of 1 part each of arsenious acid and sulphate of morphia, 8 parts of calomel, and 48 parts of powdered gum arabic. The powder was thickly strewn over the ulcer or wound every day; its action was powerfully escharotic, but painless, and it neutralized the fetor of the sore. Kaposi, after Hebra, employs a paste composed as follows: Arsenious acid gr. x, Facitious cinnabar ʒss, Rose-water ointment ʒss. "The healthy skin is not in the least affected by it, not even excoriated, whilst each individual lupus nodule is invariably and thoroughly destroyed." Labouléne removed *epitheliol* tumors without severe pain by means of 2 parts of arsenious acid, 6 parts of sulphide of mercury, and 12 parts of burnt sponge, mixed and reduced by water to a paste. He claimed that this preparation attacks the abnormal growth, and not the natural tissues (*Bull. de thérap.*, cv. 143). Koebner cured a case of multiple *sarcoma* of the skin by injecting each of the small tumors with Fowler's solution (*Archives gén.*, Avril, 1883, p. 496). Unna recommends for the treatment both of venereal and common *warts* the continuous application of mercurial ointment containing 5 per cent. of arsenic. The growths disappear by reabsorption, as in cases of spontaneous cure (*Practitioner*, xxix. 468). The peculiar caustic and drying action of arsenic has long been used to destroy the exposed pulp of *carious teeth*. About $\frac{1}{60}$ of a grain (Gm. 0.001), or from that to $\frac{1}{30}$ of a grain (Gm. 0.002), is applied to the nerve-pulp previously benumbed by some anæsthetic or astringent, and securely covered to prevent its displacement. The pain produced is severe in proportion to the inflammation of the part.

The symptoms of *poisoning* produced by arsenic taken into the stomach should be met by thoroughly evacuating that organ by means of ipecacuanha, alum, or the sulphate of zinc or copper, and the administration of tepid water containing white of egg, flour, or lime-water. If these are unsuccessful, the stomach-pump should be speedily resorted to, after which the hydrated sesquioxide of iron or the hydrated sulphuret of iron should be largely administered as a chemical antidote. The saccharated oxide of iron, solution of perchloride of iron, dialyzed iron, and also magnesia, have been recommended with the same object. The tendency of the patient to collapse is to be counteracted by means of hot bottles, bricks, etc. applied to the limbs and back, and by the cautious administration of alcoholic liquors and opiates by enema.

Administration.—The dose of arsenious acid may be stated to be between $\frac{1}{30}$ and $\frac{1}{15}$ of a grain (Gm. 0.002–0.004). Like other preparations of the medicine, it should never be given when the stomach is empty, and like them, also, its dose should be gradually increased until the eyes begin to show signs of its operation or the symptoms of the disease for which it is prescribed are ameliorated.

ACIDUM BENZOICUM, U. S., Br., P. G.—BENZOIC ACID.

Acidum benzoicum sublimatum, Flores benzoës.—*Flowers of benzoin, E.; Acide benzoïque, Fleurs de benjoin, Fr.; Benzoësiure, Benzoëblumen, G.*

Formula $\text{HC}_7\text{H}_5\text{O}_2 = \text{C}_6\text{H}_5\text{COOH}$. Molecular weight 122.

Origin.—Benzoic acid is contained in benzoin, Tolu balsam, Peru balsam, storax, Botany Bay resin, in several other resinous exudations, and in certain plants. It was described by Vigenère (1608) as one of the products of the dry distillation of benzoin, and recognized by Lemery (1675) and Scheele (1775) as an acid. Liebig (1830) found it among the products of the dry distillation of hippuric acid, and Dessaignes (1847) obtained it from the latter by the action of acids and alkalies. Its artificial preparation is described below.

Preparation.—Take of Benzoin in coarse powder 12 troyounces. Spread it evenly over the bottom of an iron dish 8 inches in diameter and 2 inches deep; cover the dish with a piece of filtering-paper, and by means of paste attach it closely to the rim. Then, having prepared a conical receiver or cap of thick well-sized paper, of rather larger diameter than the dish, invert it over the latter so as to fit closely around the rim. Next apply heat by means of a sand-bath or of the iron plate of a stove, until, without much empyreuma, vapors of benzoic acid cease to rise. Lastly, separate the receiver from time to time, and remove the benzoic acid from it and the paper diaphragm as long as the acid continues to be deposited. By renewing the paper diaphragm after it has become so obstructed as to prevent the passage of vapor, an additional quantity of benzoic acid may be obtained.—U. S., 1870.

The above process and apparatus were first proposed by Mohr. The directions are plain, and if followed an excellent product will be obtained, particularly if a few precautions have been adopted. The benzoin, which may be mixed with an equal bulk of sand, should be previously deprived of all adhering moisture by keeping the coarse powder for a few days in a close vessel over burned lime, removing it to the dish only when ready for use; if this moisture be not expelled, it will condense in the cap, and with it a portion of the acid will be absorbed by the paper. Loose filtering-paper should be used for the diaphragm, so that the passage of the vapors will not be impeded. The heat should be regulated; to accomplish which it is preferable to place the dish in a sand-bath, which at the beginning of the operation should be carefully kept at a temperature of about 145°C . (293°F .), and gradually raised to 200°C . (392°F .). The operation will require about 4 hours or more, the length of time depending upon the thickness of the benzoin layer in the iron dish, upon the proper regulation of the heat, and upon the care with which the entire apparatus is handled during the operation. The sublimed acid obtained from the cooled apparatus is ready for use. The yield from good benzoin is usually from 7 to 8 per cent. A considerable portion of the acid remains in the benzoin, which, by the heat employed, has been fused. It may be obtained by breaking the mass again into small pieces, and submitting it to another sublimation, or preferably by the wet process described below.

If during the operation the apparatus should be shaken, a portion of the sublimed acid will be detached from the paper cap, and, falling upon the diaphragm, will be absorbed with the empyreumatic oils, and require to be resublimed. A change of the receiving-cap is therefore not advisable if the apparatus remains entirely undisturbed until the process is finished. To avoid these difficulties, one or two diaphragms of gauze may be inserted in the receiver a few inches above the subliming vessel, so as to retain any acid which may become accidentally detached. To attain the same end, several modifications of the apparatus described above have been proposed. Mohr covers the subliming vessel with a very shallow sheet-iron funnel, terminating in a tube about 1 inch long and about 3 inches in diameter. The receiving vessel consists of a nearly cubical box made of paste-board, and covered upon the inside with glazed paper, a circular hole, fitting closely around the tube, being cut in one side. By this arrangement very little acid can fall back into the iron dish.

Hager replaces the shallow funnel by a flat sheet-iron cover, having near the edge a tubulure, through which the termination of the sublimation may be ascertained by removing the stopper and covering the opening for a short time with glass, upon which some benzoic acid, if it still sublimes, will be deposited. The receiving vessel consists of a paste-board cylinder, terminating conically at one end, so as to fit well around the large circular tubulure in the centre of the cover. The upper end of the cylinder is closed during the

operation with a plate of glass. The insertion of one or two gauze diaphragms near the conical end is advisable.

C. Rump (1868) recommends a sheet-iron kettle 18 inches in diameter and 12 inches deep, which has inserted in it, on two opposite sides, tubes 6 inches in length and diameter, with which large paper boxes serving as receivers may be connected, into the extreme end of which a short tube is fitted to establish communication with the air. Sublimation is effected from a cast-iron or earthen dish, which is placed in the kettle and may be charged through an opening in the cover. The temperature is ascertained by means of a thermometer suspended in the vessel and passing through a tubulure in the cover. Since a portion of the acid is liable to condense on the cover, the latter should be kept hot.

Benzoic acid may also be prepared by boiling 4 parts of powdered benzoin and 1 part of lime with from 40 to 50 parts of water, filtering while hot, and supersaturating the clear liquid, after some concentration, with hydrochloric acid. In this process, which is essentially that of Scheele (1775), the benzoic acid, together with a little resin, is rendered more freely soluble in water through the formation of benzoate of calcium. This salt is decomposed in the filtrate by the hydrochloric acid, with the production of freely soluble chloride of calcium and crystallizing benzoic acid, the latter being contaminated with some resin and coloring matter, from which it may be freed by dissolving it in twenty times its weight of boiling water, adding some animal charcoal, filtering while hot, and crystallizing.

Benzoate of sodium is about fifteen times more soluble in water than the calcium salt, and from it the acid may be prepared with smaller quantities of liquid. Bucholz recommends (1810) the digestion for 3 hours, at a temperature of 40° to 60° C. (104° to 140° F.), of from 4 to 5 parts of powdered benzoin with 1 part of crystallized carbonate of sodium and 8 to 10 parts of water. The mixture may afterward be boiled, filtered, and treated as stated above in Scheele's process. If the digestion is prolonged for a day or two, care being taken not to raise the heat to such a degree that the resin fuses, boiling will not be necessary, and the pulverulent residue may easily be washed with warm water to remove the benzoate. The resin left by this process may be advantageously used in the preparation of fumigating pastilles. The acid obtained is mixed with a larger amount of resin than that obtained by the lime process.

The process suggested by Wagner (1879) has only scientific interest: Benzoin is dissolved in 3 or 4 parts of warm strong acetic acid, and the solution poured into 4 parts of boiling water, when the resin will be precipitated and the acid will crystallize from the clear liquid on cooling. Thus prepared, it has a pleasant storax-like odor.

Most of the benzoic acid of commerce is now made artificially, either from urine or from tar-products, and is employed in the preparation of blue tar-colors. The urine of cattle or horses is mixed with an excess of lime, evaporated to one-sixth or one-twelfth its volume, and supersaturated with hydrochloric acid (Gregory). The impure hippuric acid thus obtained may be purified by recrystallization after treatment with animal charcoal or with chlorinated lime, or with hydrochloric acid and some chlorate of potassium. By boiling the purified hippuric acid, $C_9H_9NO_3$, with hydrochloric acid for half an hour it is split into glyecoll, $C_2H_5NO_2$, and benzoic acid, $HC_6H_5O_2$. The latter has a fétid odor, and is purified by recrystallization from water, and sometimes by sublimation with a little benzoin.

Naphthalin, $C_{10}H_8$, which is most advantageously obtained from coal-tar, when oxidized with nitric acid yields phthalic acid, $C_8H_6O_4$, crystallizing in colorless scales or prisms, and easily soluble in hot water. This is converted into the calcium salt, which, on being mixed with calcium hydrate and heated to 300° or 350° C., is decomposed into calcium carbonate and benzoate, from the latter of which benzoic acid is liberated in the usual manner.

Recently, benzoic acid is largely manufactured from a derivative of toluol, C_7H_8 , from which benzotrichloride, trichloromethyl-benzol, or phenyl-chloroform, $C_7H_5Cl_3 = C_6H_5CCl_3$, is first obtained by passing chlorine into hot toluol. The liquid, on being treated with water under pressure, yields benzoic acid; but a more successful process is the heating of it with a mixture of acetic acid and zinc chloride, when hydrochloric acid and acetic chloride are given off, and benzoic acid remains behind with the zinc chloride.

From 8000 to 9000 pounds of benzoic acid are annually imported into this country.

Properties.—Benzoic acid is in yellowish-white feathery flexible crystalline plates and needles, having an agreeable aromatic odor and a warm acidulous taste. The odor is due to the presence of a small quantity of volatile oil, produced from the benzoin during sublimation. Exposed to the light, benzoic acid sublimed from benzoin becomes darker in color and separates a few oily drops of a brown color. The pure acid is white

and without odor. It fuses at 120.5° C. (249° F.), and boils at 239° C. (462° F.), but volatilizes freely with the vapor of boiling water, and more slowly at a somewhat lower temperature. Its vapors are suffocating and acrid, inciting to coughing. It requires for solution 1 part of boiling alcohol, and at 15° C. $2\frac{1}{2}$ parts of absolute alcohol, $2\frac{1}{2}$ parts of 90 per cent. alcohol, and 3.2 parts of absolute ether (Bourgoin). It is also soluble in fixed and volatile oils, in 10 parts of glycerin, in 15 parts of carbon bisulphide at 30° C., in 6 parts of chloroform, in benzol, and in petroleum benzin. Its solubility in water is increased by several sodium salts. According to Bourgoin, 1000 parts of distilled water dissolve—

At	0°	5°	10°	15°	20°	30°	50°	60°	70°	80°	90°	100° C.
in	1.70	1.85	2.10	2.45	2.90	4.10	7.75	11.55	17.75	27.15	40.75	58.75 parts benzoic acid.

According to R. Otto (1862), the benzoic acids obtained from different sources (benzoin, oil of bitter almond, urine, benzalanin, etc.) differ from each other in the degree of their solubility in water. The experiments of Reichenbach and Beilstein (1865), however, indicate the existence of but one variety of benzoic acid.

Its solution in strong sulphuric acid is colorless, and when gently warmed brownish, and on adding it to water benzoic acid is again precipitated; but the solution in fuming sulphuric acid, on being heated, gradually forms sulphobenzoic acid, $C_6H_5SO_3H$, which is deliquescent. Boiling nitric acid does not affect benzoic acid, but fuming nitric acid produces substitution compounds. Nascent hydrogen causes deoxidation, with the formation of benzaldehyd (oil of bitter almond) and benzalcohol, and the production of crystalline hydrobenzoic acid, $C_6H_{10}O_2$.

The chemical composition of benzoic acid is represented by the formula C_6H_5COOH . Its salts are more or less soluble in water, and many of them also in alcohol; those with the alkalies dissolve very freely in water. Solutions of the salts yield with neutral or basic ferric salts pale brownish-red, and with lead acetate and silver nitrate white, precipitates, which are sparingly soluble in water.

Tests.—Benzoic acid should completely evaporate from platinum-foil. If much charcoal be left behind, the presence of other organic substances would be indicated, of which sugar manifests itself by the odor of caramel, and hippuric acid by the odor of hydrocyanic acid, during the application of heat, while mineral substances will be left behind as a fixed residue. Since some varieties of benzoin contain cinnamic acid, this should always be tested for before benzoic acid is prepared. Its presence in the latter is readily ascertained by an oxidizing agent, such as chlorine, bichromate of potassium and sulphuric acid, or potassium permanganate, when the odor of oil of bitter almond will be perceived.

If prepared from benzotrichloride, benzoic acid is apt to contain chloro-compounds, which are detected by the blue-green color produced at the tip of a non-luminous flame when a little of the acid attached to cupric oxide is held in the flame.

Pure benzoic acid does not decolorize a solution of potassium permanganate, but the odorous compounds present in the sublimed acid rapidly deoxidize it, both in acid and alkaline solution. This test has recently (1881, 1882) been perfected by C. Schacht and others, and is applied by mixing .1 Gm. (1.5 grains) of the acid and 5 drops of permanganate solution (1 in 200) with 5 Ccm. of distilled water or with 3 Ccm. each of potassa solution, sp. gr. 1.18, and distilled water, and heating the mixture just to boiling, when complete decoloration will be at once effected without the previous production of a green color. Benzoic acid prepared artificially or by the wet process will either not reduce the permanganate, or affect it more slowly than the sublimed acid. For this reason C. Schneider has increased the test-liquid to 16 drops, which, when the mixture has been set aside for 8 hours, will be decolorized only by the sublimed acid, but not by the other kinds even if resublimed with benzoin. In the presence of cinnamic acid reduction will likewise take place, but at the same time the odor of oil of bitter almond will be observed.

Off. Prep.—Ammon. benzoas, Tinct. opii camphorata (composita), U. S., Br.; Tinct. opii ammoniata, Br.

Medical Action and Uses.—Taken internally in doses of 20 grains, and repeated several times a day, benzoic acid irritates the throat, and is said to occasion a diffused sense of warmth over the whole body, and to increase expectoration and perspiration. In the urine it is converted into hippuric acid at the expense of the urea.

It is maintained by authorities of equal weight to be no less advantageous when the urine contains an excess of *uric acid* than when it is *phosphatic*. Certainly, when the urine is excessively acid, this medicine, in doses of 10 or more grains dissolved in a weak

solution of carbonate or phosphate of sodium, will materially lessen its acidity. On the other hand, phosphatic urine may be rendered acid by means of 20 grains of benzoic acid given twice a day, and at the same time the accompanying local irritation will subside whenever the phosphatic state of the urine is due to derangements of the bladder. When, however, this condition is owing to constitutional causes, the medicine is of no avail. Phosphatic deposits are apt to arise when the urine becomes ammoniacal in the bladder from the action of fermenting mucus, and to form masses in layers upon the lining membrane, or calculous concretions of the ammoniaco-magnesian phosphate. The due administration of benzoic acid maintains the acidity of the urine and prevents the formation of such deposits. It is credited with possessing a cholagogue action, which, however, is more demonstrable in its salts.

According to Senator, who employed benzoic acid in the treatment of *rheumatism*, it is useless in the subacute forms of the disease. In the acute articular form its action was found very favorable, although inferior to that of salicylic acid, although it did not produce any disagreeable effects. On the other hand, it did not reduce the pulse or temperature as much. It was given to the extent of 2 or 3 drachms during the day (*Zeitschrift f. klin. Med.*, i. 262).

Incontinence of urine, without any altered condition of this secretion, and depending probably upon irritability of the lining membrane of the bladder, has been frequently treated by this medicine with success. It has also been used with apparent benefit in *Bright's disease* and *albuminuria*; it seemed to cause the disappearance of albumen from the urine. In *chyluria*, with spontaneously coagulable urine, it has restored the secretion to its normal condition (*Am. Jour. of Med. Sci.*, July, 1882, p. 263).

Benzoic acid has some repute as a remedy for *jaundice*, but the conditions for its successful use are undetermined. It may be assumed, however, that it can only be employed with a hope of advantage when jaundice is due to simple obstruction of the ducts by inspissated bile, whatever may be the remaining conditions of the liver.

In *chronic bronchitis* the fumes of benzoic acid have for a long time been inhaled advantageously, and recently atomized solutions of the compound tincture of benzoin, whose internal administration is of older date in the treatment of the same affection.

Administration.—The dose of benzoic acid is from 10 to 40 grains (Gm. 0.60–2.60). In albuminuria much smaller doses, as 1 or 2 grains, have been found sufficient. To promote its solution in water, 4 parts of phosphate of sodium, or 1½ parts of borate of sodium, may be added. It may also be administered in pills made either with balsam of fir or Castile soap (*Am. Jour. of Phar.*, Aug. 1880, p. 406).

ACIDUM BORICUM, U. S., P. G.—BORIC ACID.

Acidum boracicum.—*Boracic acid*, E.; *Acide borique*, Fr.; *Borsäure*, G.

Formula H_3BO_3 . Molecular weight 62.

Origin and Preparation.—This acid was obtained by Homberg (1702) by heating borax with copperas, and subsequently from sulphuric acid and borax. It was known as *Sal sedativum Hombergi* until Gay-Lussac and Thénard (1804) proved it to be an oxygen compound of boron. It is a constituent of several minerals, and is present, mostly in minute quantities, in various plants, mineral waters, and sea-water, and in somewhat larger proportion in several of the hot springs in Western North America. The crater of the Liparian island of Voleano, situated north of Sicily, contains a deposit of boric acid mixed with sulphur, and the same acid is found in the vapors which issue from fissures in the volcanic rocks of Tuscany in Italy. These fissures, called *soffioni*, are either natural or made artificially by drilling, sometimes to the depth of 150 or 200 feet. Surrounding one or more of the *soffioni* a series of basins or *lagoons* are constructed on the side of the mountain, either by excavation or masonry, and are then filled with water from a mountain-stream; the hot vapors in passing through the water yield to it boric acid and heat the water at the same time. The solution of boric acid thus obtained is passed from one basin to another lower one, and when sufficiently saturated into a reservoir; thence it is conducted into evaporating-pans, and finally into vats, where the acid is deposited. This crude product, of which about 200,000 pounds are annually imported into the United States, is used in the preparation of borax (see SODIUM BORAS), and from this salt boric acid is again prepared for medicinal use.

10 parts of borax are dissolved in 24 parts of boiling water; the solution is filtered while hot, mixed with 6 parts of hydrochloric acid, and the liquid set aside for a day in a cool place. The crystals are collected either in a funnel or upon a strainer, and are

drained and washed with a little cold water, after which they are redissolved in five times their weight of boiling distilled water. After a day or two the crystals are collected as before, washed with cold water to remove the last traces of adhering hydrochloric acid, and dried in a moderately warm place. The yield is between $5\frac{1}{2}$ and 6 parts. The reaction which takes place is explained by the equation $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O} + 2\text{HCl} = 4\text{H}_3\text{BO}_3 + 2\text{NaCl} + 5\text{H}_2\text{O}$. Sulphuric acid may be employed in the place of hydrochloric acid, but will adhere more persistently to the boric acid, necessitating two or three recrystallizations.

Properties.—Boric acid crystallizes in white, translucent six-sided scales, which have a slight pearly lustre, are somewhat fatty to the touch, inodorous, and of an acidulous and slightly acid taste. The taste of the solutions is somewhat astringent and sweetish, and in the presence of salicylic acid quite bitter. When heated it melts, disengaging vapors of water, which contain some of the acid; between 80° and 100° C. it is converted into *metaboric acid*, HBO_2 ; between 140° and 160° C. it yields *pyroboric acid*, $\text{H}_2\text{B}_4\text{O}_7$; and at a red heat all the water is expelled, *boric anhydride*, B_2O_3 , being left in the form of a transparent, very hard but brittle glass, and weighing about 56 per cent. or less of the boric acid used. Boric acid volatilizes appreciably with water at and above 60°

FIG. 5.

Crystal of Boric Acid.

C., and with the vapors of boiling alcohol; its solution in the latter burns with a green flame. It is nearly insoluble in ether, soluble in glycerin and volatile oils, and at 17° C. dissolves in 6 parts of alcohol. According to Brandes and Firnhaber (1824), 1 part of boric acid dissolves—

At 18.8°	25°	37.5°	50°	62.5°	75°	87.5°	100° C.
in 25.66	14.88	12.66	10.16	6.12	4.73	3.55	2.97 parts of water.

The solutions impart a red color to blue litmus- and a red-brown color to turmeric-paper; the last-named reaction is also produced in the presence of diluted mineral acids.

Boric acid, mixed with the salts of mineral acids and ignited, decomposes all those containing volatile acids; in aqueous solution it decomposes the carbonates only, forming borates, of which those with an alkaline base are readily soluble in water, while most others are slightly soluble or nearly insoluble. On ignition they melt to a glass-like mass, and when mixed with sulphuric acid and alcohol, on igniting the latter the green flame of free boric acid is observed.

Tests.—In addition to its fusibility, and its complete solubility in water and alcohol, boric acid, dissolved in 30 parts of distilled water acidulated with nitric acid, should yield no precipitate with the nitrates of silver and of barium (absence of hydrochloric and sulphuric acid), and no dark color with sulphydric acid either before or after neutralization with ammonia (metals). If mixed with an excess of sulphuric acid, the addition of a crystal of ferrous chloride should not cause the appearance of a dark-brown color (absence of nitrates).

Pharmaceutical Uses.—GLYCERYL BORATE or BOROGLYCERIDE has been recommended by F. S. Barff (1881) as a valuable antiseptic. It is prepared by heating 92 parts of glycerin with 62 parts of powdered boric acid to about 150° C. (302° F.) as long as aqueous vapors are given off; if the heat be further continued the product will acquire a dark color. Properly prepared, it is colorless or yellowish, solid, transparent, and soluble in alcohol and more freely in water. It is hygroscopic, and, according to T. D. McEllhenie (1882), may be conveniently moulded in camphor-ice tins and preserved by wrapping in waxed paper and tinfoil.

GLACIALIN, which has been recommended as an antiseptic and for the preservation of articles of food, is a mixture of boric acid 6 parts, borax 3 parts, sugar 3 parts, and glycerin 2 parts.

Medical History.—In 1828, Richter stated that Homberg, who discovered the acid in 1702, ascribed to it transiently stimulant, antispasmodic, anodyne, sedative, and narcotic, as well as antiputrescent, virtues. Mitscherlich noted its comparative freedom from irritant properties, and Gahn, in Sweden, called anew attention to its power of hindering putrefaction, which in recent times has been ascribed to its destroying bacteria. Cullen, however, declared that it possessed no medicinal virtues. Since 1874 it has been much used in diseases or conditions supposed to be associated with bacteria, and the most positive assertions and confident predictions have been made of its power to cure diphtheria, erysipelas, cholera, scarlatina, typhus and typhoid, intermittent and puerperal, fevers.

Action.—In 1879, J. Neumann showed that dogs, horses, rabbits, pigs, etc. were unaffected except by very large doses of the acid, and that the symptoms it produced

were due to local irritation chiefly. 3 per cent. solutions could be injected without injury into serous cavities (*Archiv Exper. Pathol.*, xiv. 149). It is an insecticide, and has been used to destroy cockroaches. Mododowski found that a 5 per cent. solution of the acid injected into the pleural cavity after paracentesis proved fatal, and a like result is attributed to injecting a lumbar abscess with a similar solution. The symptoms produced were nausea, vomiting, hiccup, and collapse. In a case reported by Huse (*Med. News*, xl. 704) the chest was washed out by a saturated solution of boracic acid. Besides the symptoms of collapse just mentioned, was observed a general erythematous eruption of the skin. This acid having been continuously applied to an ulcer of the thigh, persistent diarrhœa, and afterward vomiting which ultimately became bloody, occurred; and diuresis was followed by suppression of urine and death. The liver and kidneys were found disorganized in their glandular elements (*Med. News*, xliii. 199).

Uses.—Boracic acid has been used chiefly as an external application. According to Theobald (*Med. Record*, xvii. 140), a solution of 4 grains of the acid in an ounce of water does not irritate the conjunctiva. He used a solution of half that strength in various forms of *conjunctivitis*, accompanied or not with *corneal ulcer*. It is, however, to be noted that these beneficial results followed not only the application of the acid, but the simultaneous suspension of atropia, nitrate of silver, and other irritants that had been in use. Greene (*Boston Med. and Surg. J.*, Aug. 1880, p. 197) reports that an ointment of boracic acid is a very efficient dressing for *wounds* of large extent. Barwell and others have stated that a glycerole of the acid is superior to carbolic acid for its antiseptic and cicatrizing virtues. The antiseptic properties of this boro-glycerid have been demonstrated by ample experiment, and the advantages over iodoform, carbolic and salicylic acids, are claimed for it that it is unirritating, and promotes the rapid healing of wounds and the drying up of suppurating surfaces; *e. g.* vaginitis, purulent ophthalmia, otorrhœa, etc. (*Med. News*, xl. 304, 602). Greene ascribed to boracic acid peculiar virtues in healing *ulcers* that follow severe *burns*, and others of a foul and unhealthy aspect. He preferred for this purpose an ointment of vaseline containing the acid. On theoretical grounds Loewenberg proposed to substitute solutions of boracic acid for the usual emollient or stimulant applications to *boils*. Neumann applied boracic acid in watery solution for *parasitic diseases of the skin*, in alcohol for *pruritus* and *urticaria*, and in an ointment for *eczema*. In *psoriasis* and *herpes tonsurans* solutions of from 10 to 20 parts of the acid to 300 of water have been recommended. According to Kurz, a vaseline ointment containing about 5 parts of the acid to 10 or 15 of the excipient is a very serviceable application to *eczema*, *impetigo*, *prurigo*, and non-syphilitic *psoriasis*. Greene used a lotion and also an ointment of the acid in *erythema*, *erysipelas*, and *tinea*. In cases of chronic inflammation of mucous membranes attended with an unhealthy and especially a fetid discharge, such as *nasal catarrh*, *ozæna*, *cystitis*, etc., injections containing about 8 grains of the acid to an ounce of water have been found to correct the fetor and cure the discharge. It has also been used internally (Rosenthal) in conjunction with its topical application. A similar solution is reported to have greatly palliated the coryza of *hay fever* (Atkinson). A 1 or 2 per cent. solution, used as an injection, has cured *gonorrhœa* (Kurz; Hill). *Fetor of the feet* has been corrected by causing the patient to wear stockings that had been soaked in a saturated solution of boracic acid and then dried (*Practitioner*, xxvii. 401). Greene, and also Harries, found it useful as a topical application in "diphtheritic and aphthous inflammation of the fauces."

Internally, boracic acid is said to correct the fetid and other eructations that are apt to attend fermentative *dyspepsia*. The very improbable statement is made by a medical officer of the Madras service that every case of cholera recovered that was treated by him with 10-grain doses of this agent every 2 hours, associated with borax.

Administration.—The strength of the solutions for topical use has already been indicated. Internally, according to Atkinson (*Practitioner*, xxiv. 254), the dose is from 5 to 15 grains; but Greene (*loc. cit.*) says, "I have repeatedly given at a dose 4 fluid-ounces of a saturated solution which contained about 80 grains of the acid, and in several instances patients have taken much more. I have never known any ill effects from it in any way. My ordinary dose for an adult is from 20 to 30 grains." It may be given in wafers.

ACIDUM CARBOLICUM, U. S.; Br.—CARBOLIC ACID.

Acidum phenicum s. *phenylicum*, Phenol.—Phenic acid, Phenylie alcohol, Phenol, E.; *Acide phénique*, *Acide carbolique*, *Hydrate de phényle*, Fr.; *Carbolsäure*, *Phenylsäure*, *Phenylalkohol*, G.

Formula $\text{HC}_6\text{H}_5\text{O} = \text{C}_6\text{H}_5\text{OH}$. Molecular weight 94.

Origin.—Carbolic acid occurs in castoreum, in the urine of man and of herbivorous animals, and in the products of the dry distillation of various organic substances, such as resins, bones, wood, and more especially coal. It is from the latter source that it is obtained in the arts. It was first obtained by Runge (1834), and in a purer condition by Laurent (1840), who ascertained its composition and chemical behavior.

Preparation.—That portion of coal-tar which is known as *dead oil* is subjected to distillation. The portion distilling between 150° and 200° C. (302° and 392° F.) is collected separately, and is twice rectified between 170° and 190° C. (338° and 374° F.). The product thus obtained is sold as *crude carbolic acid*, *acidum carbolicum crudum s. impurum*, U. S., P. G.; *acide phénique cru*, Fr.; *Rohe Carbonsäure*, G. For the purification of this product it is agitated with warm concentrated solution of potassa or soda, when a crystalline mass of phenol sodium or phenol potassium is obtained, from which the oily liquid is poured off. The solid mass on being heated to about 170° C. (338° F.) parts with a portion of the adhering empyreumatic products, and on being dissolved in water more of the oily impurities separate, and are removed from the aqueous solution, which, on being supersaturated with hydrochloric acid, yields the phenol in the form of an oily liquid. This is repeatedly agitated with solution of table-salt, then digested with chloride of calcium for the purpose of removing the water, and distilled. The portion passing over between 180° and 190° C. (336° and 374° F.) is collected separately and exposed to a low temperature, when it solidifies into a crystalline mass, from which the mother-liquor is drained off and expressed. It may be again distilled or further purified by combining again with alkali and repeating the operations described before.

This is essentially the process of Laurent (1844). Another, proposed by H. Müller (1865), differs from the preceding mainly in the following particulars: The potassium or sodium phenylate is diluted with water as long as naphthalin and other empyreumatic products are separated. The liquid is exposed to the air for some days, by which it acquires a dark-brown color. It is filtered from the precipitated oxidation products, and then mixed with one-eighth or one-sixth of the total amount of sulphuric acid which is necessary for the complete decomposition of the phenylate. Empyreumatic resins are thus separated, and on the addition of a second similar quantity of acid more resinous products and cresylic alcohol are removed, so that a third portion of the acid usually separates almost pure carbolic acid, requiring distillation to obtain it crystallized. It is obvious that if either process be interrupted at different points, carbolic acid varying greatly in degree of purity must be obtained.

Crude carbolic acid may, according to H. Müller, be purified by treating it several times with soda solution sufficient to combine only with a fractional portion of the phenol. The solutions first obtained contain the acid in a purer condition than the last; but, as stated above, they require dilution with water and exposure to the air.

Absolutely pure carbolic acid is obtained by Church (1871) from the nearly pure commercial product by treating it with a quantity of water (about 20 parts) insufficient to dissolve it completely, removing the undissolved portion, and saturating the clear aqueous solution with pure table-salt, when the carbolic acid will separate as an oily layer, requiring distillation over some quicklime to obtain it crystallized. The portion passing up to 185° C. (365° F.) has, at ordinary temperatures, merely a very faint aromatic odor.

Pure carbolic acid is chiefly imported from England; most of the impure acid, and a very fair quality of nearly pure acid, used in this country are manufactured here. 68,000 pounds of carbolic acid were imported in 1878, and 115,691 pounds in 1881.

Properties.—Crude carbolic acid is rarely colorless. It usually has a more or less dark-brown color, caused by the impurities derived from the coal-tar. The better qualities crystallize almost completely below the ordinary temperature, the solidifying point being influenced by the amount of water and of oily impurities present in it. The latter are estimated by agitating the impure acid with two hundred times its bulk of warm water, and allowing the oily matters to separate, when they should measure not over 10 per cent. of the measure of acid employed.—U. S. The aqueous solution should not have an alkaline reaction upon test-paper, thus indicating that it is not an alkaline solution of carbolic acid; and if it yields a clear solution with water, not less than 15 parts of this solvent should be necessary for this purpose. Its odor is more or less empyreumatic. In all other respects its properties agree with those of pure carbolic acid.

Absolutely pure carbolic acid has a faint aromatic odor, is colorless, crystallizes in needles, and does not absorb moisture from the atmosphere (Moss, 1875). Usually, however, it retains a minute quantity of water, by which it becomes deliquescent; with a little more

of water it forms an oily liquid, which crystallizes at a lower temperature, and if traces of the tar-products are present it acquires a reddish color on exposure, and deliquesces to a brown-colored oil. The red color may also be produced in the dark by ammonium nitrite present in the atmosphere. The odor is modified by the presence of a little cresol. Carbolie acid is insoluble in benzin, but freely soluble in alcohol, ether, glycerin, the essential and fatty oils, in glacial acetic acid, caustic alkalies, carbon bisulphide, and chloroform, the solutions in the last two liquids separating all the water present, the amount of which may thus be determined. Morson (1872) observed that the oily liquid, either pure or containing creasote, will dissolve in an equal bulk of glycerin, and not be reprecipitated by water. (See CREASOTUM.) Carbolie acid dissolves at 15° C. (59° F.) in 20 parts, or, according to Hamberg (1871), in 15 parts, of water between 16° and 17° C. (60.8° and 62.6° F.). The solution is perfectly transparent, and is without action upon litmus-paper. Carbolie acid is less soluble in many saline solutions than in water; it yields with a limited amount of concentrated solutions of the fixed alkalies a crystalline mass, which, after being pressed, consists merely of carbolie acid, and is almost free from potassa (Calvert, 1865). Baumann (1877) observed that carbolie acid slowly decomposes a boiling solution of potassium carbonate, forming potassium phenol, which may be obtained in crystals from alcoholic ether. The fusing-point of crystallized carbolie acid is influenced by the amount of water with which it is combined; pure carbolie acid fuses at 44° C. (112.2° F.), and boils at 187° to 187.8° C. (368.6° to 370° F.) (Flückiger), or at 187.8° C. (370° F.) (*Br.*). Hamberg determined the boiling-point to be 180.5° C. (357° F.). The U. S. Pharmacopeia admits carbolie acid having a melting-point of between 36° and 42° C. (96.8° and 107.6° F.) and a boiling-point of 181° to 186° C. (357.8° to 366.8° F.), and regards the higher melting- and lower boiling-points as those of the pure and anhydrous acid. (See below, CRESOL.) Carbolie acid volatilizes slowly at ordinary temperatures, rapidly at the temperature of boiling water, without leaving any residue. It has the specific gravity 1.065, separates nitrocellulose in a gelatinous form from collodion, coagulates albumen, and has a caustic acid taste, but when largely diluted with water tastes sweetish and smoky.

A piece of pine wood dipped into an alkaline solution of the acid, and afterward into hydrochloric acid, assumes in the course of half an hour a deep-blue color. According to Tiemann and Haarmann, this color is a characteristic reaction of coniferin. The solution of carbolie acid has no effect on polarized light. The concentrated alcoholic solution yields with ferric chloride a brown liquid, which on the addition of much water remains transparent and assumes a beautiful and permanently violet-blue color (Flückiger, 1872). When heated in sealed tubes with ammonia it yields but small quantities of phenylamine (aniline, $C_6H_5H_2N$). Fused with excess of potassa, oxybenzoic and salicylic acids are found among the products of decomposition. It is oxidized by permanganate of potassium, yielding carbonic and oxalic acids. Concentrated sulphuric acid converts it into sulphocarbolie (phenolsulphonic) acid, $C_6H_5HSO_4$. Under the influence of nitric acid several substitution-products are formed, the most important of which is picric acid. Substitution-compounds are likewise formed with chlorine, iodine, and bromine. The last-named element, acting either in the form of vapor or as bromine-water upon an aqueous solution of carbolie acid, produces a flocculent white precipitate of tribromophenol, $C_6H_3Br_3O$, which crystallizes from alcohol in silky needles, melting at 98° C. (208.4° F.). This reaction was recommended by Degener (1880) for the quantitative determination of phenol, and is so delicate that a solution of the latter in 57,000 parts of water is still rendered turbid; it must, however, be remembered that alkaloids and various other compounds are likewise precipitated by bromine-water.

Tests.—The purity of carbolie acid is recognized by the properties described above, by the absence of all reaction upon blue and red litmus-paper, and by the non-production of a dark color or precipitate in the aqueous solution by sulphydric acid, proving the absence of metallic compounds.

To estimate the quality of commercial carbolie acid, Schoedler (1872) recommends the heating of 3 Gm. in a water-bath to expel alcohol, if present, then the addition of 3 Gm. of sulphuric acid, and the digestion of the mixture for some time at a temperature of 50° to 60° C. (122° to 144° F.). It is then diluted with water, treated with an excess of carbonate of barium, and filtered from the precipitate, which is well washed. The sulphocarbonate of barium contained in the filtrate is then precipitated by sulphuric acid, the sulphate of barium is collected, washed, ignited, and weighed; 100 parts of barium sulphate correspond to 80.69 parts of anhydrous phenol.

The presence of carbolie acid in watery solution may be detected, according to E. Hoff-

mann (1879), by pouring into a test-tube 1 or 2 Ccm. of pure sulphuric acid, adding but not mixing the same volume of aqueous liquid, and dropping in small particles of potassium nitrate, each of which will produce a deep-violet streak; on agitation the liquid becomes violet, and on the addition of water assumes a red-orange color; $\frac{1}{10}$ per cent. of carbolic acid is thus detected. Salkowski's (1872) process consists in adding to the suspected liquid one-fourth its volume of ammonia, and then a few drops of solution of chlorinated lime (1 part to 20 parts of water). On the application of a moderate heat, a blue or greenish color will be produced, either immediately or in the course of 15 minutes, the color changing to red upon acidulating with sulphuric or hydrochloric acid; 1 part of carbolic acid in 4000 may thus be detected. Bromine may be used in place of the chlorinated solution; the blue compound is insoluble in ether and chloroform, dissolves in alcohol with a green color, and changes with acids to red, but becomes blue again by ammonia. Of still greater delicacy (1 in 200,000) is the test suggested by Plugge (1872); when a liquid containing carbolic acid is boiled with a little solution of mercurous nitrate containing a trace of nitrous acid, a reduction of the mercurous salt occurs, and the liquid assumes, sooner or later, an intense red color.

Pharmaceutical Uses.—*ACIDUM CARBOLICUM LIQUEFACTUM*. *P. G.* Pure carbolic acid, liquefied with 10 per cent. of water, or, as proposed by O. Facilides (1872), with the same quantity of glycerin; 11 grains of this liquid contain 10 grains of carbolic acid.

AQUA ACIDI CARBOLICI; Carbolic acid water, *E.*; Eau pheniqué, *Fr.*; Carbolsäure-Wasser, *G.* Dissolve glycerite of carbolic acid 10 fluidrachms in sufficient distilled water to obtain 1 pint.—*U. S.*, 1870.

LISTER'S CATGUT, for ligatures, is prepared by immersing for 2 days 200 parts of catgut in a fresh mixture of 200 parts of phenol with 4000 parts of water containing 1 part of chromic acid in solution; the string is then dried without untwisting it, and preserved in a solution of 1 part of phenol in 5 parts of olive oil.

Phenol is extensively employed in the manufacture of salicylic acid and of various dyestuffs, like picric acid, phenyl-brown, corallin (scarlet), peonin (red), aurin (yellow), azulin (blue), and others.

Off. Prep.—Glyceritum (glycerinum) acidi carbolici, *U. S.*, *Br.*; Suppositoria acidi carbolici, *U. S.*; Suppositoria acidi carbolici cum sapone, *Br.*; Ung. acidi carbolici, *U. S.*

Allied Compounds.—*ACIDUM CRESYLICUM* s. *CRESOLUM*, Cresol or Cresylic acid, $C_7H_8O = C_6H_4OH$. Among the constituents of coal-tar and of beechwood-tar there are found two compounds having this composition, *ortho*cresol and *para*cresol, which cannot be easily separated. They form colorless prisms, have a phenol-like odor, and dissolve sparingly in water, yielding solutions which are colored blue by ferric chloride. *Ortho*cresol melts at 31° C. (87.8° F.), boils at 185° C. (365° F.), and by prolonged heating with potassa is converted into salicylic acid. *Para*cresol melts at 36° C. (96.8° F.), boils at 198° C. (388.4° F.), and by heating with potassa is converted into *para*oxybenzoic acid. The presence of cresols in carbolic acid decreases the melting-point and increases the boiling-point of the latter.

Physiological Action.—*On Animals*: A detailed account of the operation of carbolic acid upon the lower animals may serve to illustrate its action on man when taken in poisonous doses, but can have only a slight bearing upon its therapeutical employment, which is confined almost exclusively to its use in checking fermentation and as a local stimulant. The experiments of Sternberg and others show conclusively that a belief in the power of carbolic acid emanations to "disinfect" the atmosphere of chambers, etc. is entirely without rational support. A very small portion of the acid in water is speedily fatal to minute organisms which may be present in the liquid. It is equally destructive to ascarides, earthworms, caterpillars, fleas, moths, ants, and other insects. Fish, frogs, and leeches soon die in a solution of 5 per cent. strength. 2 or 3 drops applied under the wing of a sparrow will produce fatal convulsions. A 5 per cent. solution administered to dogs occasions convulsions, and then paralysis of sense and motion. After the animal's death there is found congestion of the brain, lungs, and bowels, but the blood is not notably affected. A solution of 1 part of the acid in 4 parts of alcohol, applied to a dog's ear, produced circumscribed swelling and an eschar; subsequently the tissues were found mummified and translucent, without being disorganized. The experiments of Prudden on the action of carbolic acid upon ciliated cells and white blood-cells (*Am. Jour. of Med. Sci.*, Jan. 1881, p. 82) led him to conclude that dilute solutions of the acid produce a retardation or a temporary cessation of movement in living white blood-cells, while strong solutions cause the immediate arrest of their movements, and their death; but he abstained from concluding that this action explains the alleged value of carbolic acid in promoting the healing of wounds.

On Man: The principal effects produced on man by doses of 6 or 8 grains of carbolic acid in a wineglassful of water are the following: numbness, followed by a sense of coolness in the mouth and lips; if the stomach is empty, nausea and an uneasy sensation in the abdomen, with vertigo, ringing in the ears, and slight deafness; the force and frequency of the cardiac and arterial impulses decline, and sometimes diarrhœa occurs. The urine is generally diminished, and its specific gravity is raised; it also is apt to be colored brown or black, according to the quantity of the acid employed, whether it be taken internally or applied to a raw surface of the skin, but this effect is more usual after its external use or when it is applied to a serous membrane. Injected into the pleural cavity, it has changed the color of the urine to an almost inky blackness. It has been noticed in the urine of a nursing infant while the mother was using the acid. This effect would seem most apt to occur when the urine is albuminous, and especially during Bright's disease. Occasionally in the same cases it varies from day to day, although the dose of the medicine and the condition of the patient appear to be unchanged. The characteristic color is not always visible when the urine is passed, and may not appear for 48 hours. It is therefore important to detect the presence of the acid as early as possible by other means. It results from Baumann and Herter's observations that as soon as the acid appears in the urine the sulphates begin to disappear from that excretion. The diminution of the sulphates may be detected, after removing any albumen that may be present, by boiling the urine, acidulating with acetic acid, and adding chloride of barium in excess. If the sulphates abound a milky cloud will be produced. Or if 20 Cem. of the urine be treated with 10 drops of nitric acid and evaporated to dryness, and the residue dissolved in 10 Cem. of rectified alcohol and filtered, the resulting liquid will have a red color (Tortora). Or, having abstracted the acid from the urine by means of ether, soak a chip of soft wood in the solution, and dip it into a solution containing 50 Cem. each of hydrochloric acid and distilled water, to which add 20 centig. of potassium chlorate. If the chip after immersion in this solution and exposure to the sunlight turns blue, carbolic acid is present (Tommasi).

In the case of a boy four years old, suffering from bloody stools, an enema of 2 pints of water containing 2 teaspoonfuls of dissolved crystals of carbolic acid was prepared, of which about three-fourths were administered. The respiration became superficial and rapid; the pulse rose to 160, but in the course of 2 hours fell to 120. The bowel was meanwhile washed out with water, but the boy showed no signs of consciousness until the end of 2 hours. He was perfectly anesthetized. He then slept 2 hours more, naturally, and the next day was as well as ever (Putnam). A woman suffering from diarrhœa received an enema of about 8 ounces of a 1 per cent. solution of carbolic acid. Tinnitus, giddiness, and faintness immediately ensued, although the injection was passed (*Phila. Med. Times*, x. 249). Two children, five years and eight years old, had given them for the removal of seat-worms an enema made with 70 drops of carbolic acid in a pint of water. They talked incoherently, wandered restlessly about the room, then became unconscious; the pupils were dilated, the skin of the head hot, and elsewhere perspiring. The pulse was full and frequent. Coma followed, gradually merging into somnolence, and then consciousness returned (Vinke, *Med. News*, xliii. 52). In another case no less than 144 grains of carbolic acid in 18 ounces of water were injected into the bowel of a boy of five years. In a few minutes he fell into a collapse, and remained unconscious for 6 hours, but at the end of 15 hours died in convulsions (*Jour. Amer. Med. Assoc.*, i. 145). Applied externally as a surgical dressing, carbolic acid may act poisonously in two different ways. In the first the patient suddenly and rapidly sinks after the application. The second form is more insidious, and may not be developed for several weeks. The patient is nauseated, grows restless and hot, and unless the carbolized dressings are suspended, he becomes affected with giddiness, spasms, prostration, and coma, ending in death. The poison may act through a very slight lesion of the skin, as in a case of herpes zoster (Paul, *Phila. Med. Times*, May, 1880, p. 406). In the case of an infant fourteen months old it acted as a caustic on the sound skin, and speedily proved fatal (Zillner, *ibid.*, p. 325). Several other deaths occurring under analogous circumstances are on record (*Med. Record*, xxii. 672). A very complete account of the symptoms of carbolic-acid poisoning, with a rationale of their production, is contained in a paper by Reichert (*Amer. Jour. of Med. Sci.*, Oct. 1881, p. 441). It is based on an analysis of fifty-six cases, of which thirty-three terminated fatally. In some cases the toxic symptoms are almost instantly developed (Müller, *Virchow's Archiv*, lxxxv. 236).

In poisonous doses carbolic acid produces an intense burning pain in the throat and

stomach, followed by impaired muscular power and insensibility. The face is pale, the lips and hands livid; the pupils are dilated if death is rapid, otherwise they are contracted; the breath smells of the acid; the tongue is swollen, and a discolored foam is upon the lips; the respiration is stertorous, and the lungs are filled with dry or mucous rhonchi: the pulse may be rapid, or, on the other hand, abnormally slow; the urine is suppressed usually, but sometimes is copious; the bowels are generally not disturbed. Convulsions are not usual, but Treube has referred to twelve cases in which they occurred (*Philad. Med. Times*, March, 1881, p. 403), and in the New York City Insane Asylum a case was observed with clonic convulsions, unilateral at first, and then becoming general. Death may occur as quickly as 3 minutes after a large draught of the liquid, but usually in fatal cases life is prolonged for from 1 to 3 hours. The lesions found after death are: a purplish hue of the skin in dependent parts; a white or brown, dry, and shrivelled condition of the mouth, throat, and œsophagus; the gastric mucous membrane is more or less reddened, but also presents whitish patches, and is easily stripped off. The air-passages contain bloody and frothy mucus; the heart sometimes presents traces of fatty degeneration; it may be engorged or empty, but frequently contains firm clots; the brain is congested; the kidneys present no constant lesions, but in one case, at least, the epithelium of the convoluted and straight tubes showed extensive fatty degeneration (Bradford). In many cases carbolic acid has been detected in the urine. Poisonous effects may follow the external use of the acid, as numerous and even fatal cases attest. The toxic phenomena are chiefly those already mentioned as affecting the nervous and circulatory system—insensibility, feeble pulse, livid skin, cold and clammy sweat, dilated pupils, and collapse. In cases that terminate favorably these symptoms are replaced by stupor, debility, a feeble pulse, cold skin, etc. Vomiting, diarrhœa, and either an increase or a diminution of the secretion of urine has been observed. The local action of carbolic acid, when applied to the sound skin, consists in a burning or tingling sensation, followed by a marked diminution of sensibility. The part then undergoes a sort of mummification, as in the case of the experiments on animals before noticed. There are cases in which, after the finger had been immersed in strong carbolic acid, this condition was established, and amputation of the part became necessary. A case is also reported in which a finger affected with onychia was enveloped in cloths saturated with carbolic acid. The finger became mummified apparently, and yet was saved with the loss of the integuments (*Western Med. Reporter; Practitioner*, xxx. 132). The local anæsthesia referred to has been taken advantage of to render certain superficial operations painless.

The treatment of poisoning by carbolic acid consists in evacuating the stomach by copious albuminous drinks, such as milk or white of egg, or by the stomach-pump injecting and then withdrawing such liquids. Oil is also of use by rendering the action of the acid less concentrated and by delaying its absorption. According to Baumann, any soluble sulphate is a direct chemical antidote to carbolic acid; and Sonnenburg states that in a case of poisoning presenting dark urine destitute of sulphates the bad symptoms all disappeared under the use of sodium sulphate. The dose recommended for adults is a tablespoonful every half hour of a solution containing 5 parts of the sulphate of sodium in from 100 to 200 parts of water, and for children a solution of about half this strength (*Practitioner*, xxiv. 299). These statements were confirmed by Cerna's experiments upon animals (*Philad. Med. Times*, ix. 592). Saccharated lime-water has also been recommended. The tendency to collapse should be combated by dry heat and by enemata containing some alcoholic liquid or ether, or by the inhalation of the latter.

Medical Uses.—Carbolic acid has been used as an antipyretic, and especially in *typhoid fever*. It undoubtedly lowers the temperature through its poisonous operation, but no more than any other active medicine does it either reduce the mortality or abridge the duration of the disease. The chief use of carbolic acid in medicine is to prevent or delay *fermentation*, especially of the putrefactive sort. Its power, in this respect, is almost identical with that of the closely analogous product, creasote. It is supposed to act by preventing the production and multiplication of certain minute organisms upon which this process is assumed to depend. Whether these organisms are the causes, the concomitants, or the consequences of the process in question is not fully determined; but that carbolic acid restricts *suppuration* and neutralizes the foul *smells* which accompany fermentation and gangrene, as well as those extricated during all forms of *putrefaction*, including the effluvia of dissecting-rooms, privies, sewers, drains, etc., has become a matter of familiar experience. Its influence in promoting the cicatrization of *wounds* is readily understood without the necessity of invoking its antiseptic qualities, for, like many allied

substances (alcohol, creasote, terebinthines), it operates as a stimulant of the parts to which it is applied, contracting and hardening them, while it protects them from the action of the atmosphere, and thereby limits those secretions which tend to prevent union in wounds, while it favors the natural processes through which alone healing can take place. On the theory that they act antiseptically, carbolic-acid dressings have been very extensively used in this country and in Europe, but most of all in Great Britain under the influence of Prof. Lister. The general result is that accidental or surgical wounds treated by carbolic-acid dressings, with a complete exclusion of the air, are healed with much less fever and suffering and in a shorter time than by any other method. These benefits are very conspicuous in the treatment of wounded or diseased joints and compound fractures, of chronic abscess, and incisions made for the ligation of arteries. The mode of employing the method it would be foreign to the purpose of this work to describe; suffice it to say that as little as possible of the acid should be applied to the affected tissues, but a liberal proportion to the dressings. In this manner the risks of poisoning are diminished. That result was met with five times in the course of 4 years by Küster, and of these cases four were fatal. The same surgeon, examining the experience of others, found seven mild cases of carbolic acid poisoning with one death, and thirteen severe cases with five deaths. Children are peculiarly liable to this danger. Ever since the first introduction of carbolic-acid dressings into surgery it has been assumed that they owed their advantages exclusively to the antiseptic virtues of the acid. But, as was intimated in the second edition of this work, and is repeated above, the exclusion of air is an essential part of all antiseptic dressings. It remained, then, to be determined whether or not the exclusion of air and of all mechanical hindrances to cicatrization formed an indispensable condition for the primary healing of wounds. In the antiseptic method, as originally practised by Mr. Lister, carbolic acid was not applied in spray, but only in lotions, injections, and the like. The observations and experiments of Trondelenburg, Von Bruns, and others led them to the disuse of the spray as unnecessary and disagreeable, but they still employ the acid to neutralize the poisons which, as they conceive, hinder the healing of wounds, occasion erysipelas, pyæmia, etc. Billroth, after sufficient trial, abandoned carbolic acid as a surgical dressing. Perhaps it may be found that the absolute cleanliness of every person and thing concerned in an operation or dressing is, next to a perfect coaptation of the divided tissues, the essential condition of their healing; and that with this precaution carbolic acid, like the sympathetic powder, would cure a wound if applied upon the weapon that inflicted it almost as perfectly as if it were irrigated or sprayed upon the wound itself.

It would seem that carbolized oil is not as apt as carbolic acid diluted with water to occasion symptoms of poisoning. The combined antiseptic and stimulant properties of the latter are serviceable in many cases of *gangrene*, both traumatic and spontaneous, as in *noma pudendi*, *gangrene of the lung*, and in those cases of fetid discharge from the lungs which are sometimes so distressing in *phthisis* and *chronic bronchitis*. In the last-named affections it also tends to lessen the secretion of mucus and pus, and is best employed in the form of an atomized spray. In tubercular phthisis it is often of service by preventing vomiting. It is unnecessary to say that it has no influence upon the tubercular element of the disease; but it does modify very greatly the ulcerative lesions of the lungs and bronchia, just as it does wounds and ulcers upon the skin, and just as the same effect is produced by various other stimulants, including benzoin, creasote, naphtha, oil of turpentine, etc. Years ago the emanations of illuminating gas manufactories were supposed to cure *whooping cough*, and carbolic acid has been applied, in imitation of that treatment, by inhalation. Some have used the atmosphere of a room impregnated with carbolic acid evaporated from extended cloths, others an atomized solution of from 1 to 2 per cent. strength (Thomer; J. L. Smith). The latter was applied three times a day, and seems to have promptly diminished the number of paroxysms and shortened the duration of the attack. In *diphtheria* the inhalation of a 1 or 2 per cent. solution of the acid has been alleged to dissolve the false membrane (Seiffert); and others have applied with a brush a mixture of equal parts of carbolic acid and glycerin, and limited its caustic action with iodoform (Garnett). Carbolized camphor has been used in the same manner with like results (Peraté). These methods may be of use as local palliatives, but diphtheria is not a merely local disease. The treatment of surgical *erysipelas* with hypodermic injections of a 3 per cent. solution of carbolic acid was practised by Hueter in 1878. The punctures were made at intervals upon the edge of the inflammation. Rothe used a liniment containing, besides carbolic acid, oil of turpentine and tincture of iodine, so that the share

of the acid in the result cannot be estimated. Tassi applied a "saturated solution" of the acid; and Radcliffe, 1 part of the acid to 16 of olive oil as a liniment in an aggravated case of erysipelas of a lower extremity, with immediate relief and rapid amendment (*Philad. Med. Times*, April, 1881, p. 455). Dr. Squibb found, from extensive experience in his laboratory, that a $\frac{1}{2}$ to 1 per cent. solution applied by means of thin cloths, frequently renewed, will relieve the pain of *burns* within 10 minutes, prevent the suppuration of superficial burns, and moderate that of deeper ones (*Ephemeris*, i. 307). In a gargle it may be used to cure affections of the *throat* accompanied with a fetid secretion. Its antiseptic virtues are displayed in fermentative or flatulent *dyspepsia*, although they are inferior to those of sulphurous acid and of salicylic acid. Several physicians (Rothe; Shelly) on theoretical grounds have used this acid in the treatment of *typhoid fever*, and with alleged excellent results. It has not yet been thoroughly tested, but the failure hitherto of all active methods of treatment, and the relative success of the expectant plan, indicate that the carbolic acid treatment is not worthy of confidence. It is said to be an efficient remedy for *ascarides* of the rectum, when administered by enema and sufficiently diluted to prevent excessive irritation. 6 ounces of the one-fortieth or one-sixtieth solution have been used for adults, but it is apt to occasion unpleasant symptoms. The medicine has been given by the mouth with alleged success for the expulsion of *lumbri-coid worms*, and is reported to have destroyed *tænia* when administered in the dose of 6 grains in half a pint of water, four times a day (Bill), or of 2 grains in pill every 3 hours until 4 doses were taken (Brown), or of $2\frac{1}{2}$ grains in half an ounce of water three times a day (Maxwell). The method does not seem to have proved acceptable. The cor-rugating and more or less caustic and yet anæsthetic operation of the acid has been employed in the treatment of *polypi*, *venereal vegetations*, *navi*, *boils*, *carbuncles*, *whitlows*, *uterine ulcers*, etc. The injection of swollen and inflamed *hæmorrhoids* with a strong solution of concentrated carbolic acid has been recommended, but practised chiefly by irregular physicians; the method has been denounced as painful, and dangerous from the risk of causing peritonitis, pyæmia, or hepatic embolism. The latter view appears to be the more correct of the two. A 2 to 5 per cent. solution of the acid in olive oil or glycerin was used, of which from 2 to 4 drops were injected at intervals of from 4 to 10 days. The needle was sharp and the injection made slowly, and only one pile attacked at a time; the rectum was stuffed to prevent embolism, and the patient was kept in bed for 8 or 10 hours after each injection (Andrews). In *hydrocele* concentrated carbolic acid has been injected into the cavity (Levis), and the cure is represented to have been painless as well as radical. On the other hand, severe inflammation and non-success have been known to follow it (*Philad. Med. Times*, xi. 90). For *sore nipples* a 5 per cent. solution of the acid, applied by means of a fine brush to the fissures, has proved very efficient. According to Schwimmer, a paste composed of carbolic acid 4 to 10 parts, olive oil 40 parts, finely-powdered prepared chalk 60 parts, applied to the face on a linen mask, causes the pustules of small-pox to dry some days earlier than usual. A lotion of carbolic acid is convenient to lessen the discharge and correct the fetor of *otorrhœa*. There is reason for admitting the efficacy of a solution of 1 part of carbolic acid in 3 or 4 of alcohol in curing recent *acne rosacea*. That most obstinate of cutaneous affections, *prurigo*, is said to have been cured in some instances by carbolic acid (Geber), but as arsenic was given internally at the same time, the conclusion is not certain. The acid is, however, very efficient in allaying the itching of this affection when applied in a 2 per cent. solution, atomized or in lotion (Lailler). A mixture of 1 part of carbolic acid and 2 or 3 of glycerin has been advantageously applied several times a day by means of a mop to the crusts in *ringworm of the scalp* (A. Smith). The cure of alarming symptoms produced by the *sting of a bee* has been attributed to the hypodermic injection of 5 milligrams of this acid in solution (Klamann). A weak solution of the acid forms a suitable lotion for diphtherial and other forms of *sore throat* attended with fetid discharges. Like creasote, it is an efficient palliative for *toothache* due to an exposed nerve-pulp. Idiopathic *sciatica* and some other neuralgic and rheumatic pains are said by Schruppf to have been cured by deep injections of from 1 to 3 per cent. solutions of this acid (*Med. News*, xlii. 386). It is known that similar injections of pure water have been followed by a like result. Kurz used this method for muscular *rheumatism* (*Med. Record*, xxiii. 208), but, we must believe, without necessity, considering the many ways in which this affection may be cured.

The power of the acid to check fermentation has led to its use in the treatment of *saccharine diabetes*, on the supposition that the disease is due to an increase of the ferment, which in the liver converts amyloid substance into sugar. The suggestion does not appear

to have led to any confirmation of its value. It may be mentioned, only to condemn it, that carbolic acid has been administered as an antipyretic by Desplats.

The dose of carbolic acid is 1 or 2 grains or drops (Gm. 0.06–0.13). An atomized inhalation may be used, consisting of 2 or 3 drops of the acid in an ounce of water (Gm. 0.10–0.20 in Gm. 32) to which a little glycerin has been added. For a gargle, about 20 drops of the acid in from 2 to 4 fluidounces (Gm. 60–120) of water and glycerin may be employed. In the following solution the odor of the carbolic acid is masked: carbolic acid, 1 part; oil of lemon, 3 parts; alcohol, 100 parts. A preparation known as carbolized cotton is used as a surgical dressing.

Carbolic acid water (*U. S. P.* 1870) was intended to furnish a perfect solution of carbolic acid of determinate strength. 1 pint of it contained about 2 fluidrachms of the acid, and it was given internally in the dose of from $\frac{1}{2}$ a fluidrachm to 1 fluidrachm (Gm. 2–4). It is a convenient preparation for use in atomization, as a gargle, and as a wash in various cutaneous diseases.

CRESYLIC ACID has been used successfully to mitigate the paroxysms of *whooping cough*, when its vapors were diffused through the chambers occupied by the patients (Merritt, *Med. Record*, xvi. 549).

ACIDUM CARBONICUM.—CARBONIC ACID.

Carbonic anhydride, Carbon dioxide, E.; Acide carbonique, Fr.; Kohlensäure, G.

Formula $\text{CO}_2 = \text{OCO}$. Molecular weight 44.

Formation and Preparation.—Carbonic acid gas, as it exists in certain mineral waters, was regarded by Libavius (1597) as a very volatile spirit. In the following century Van Helmont distinguished it and other irrespirable gases from atmospheric air as “spiritus sylvestris” or “gas sylvestre.” In the beginning of the eighteenth century F. Hoffmann recognized the acid character of carbonic acid in mineral waters, and called it “spiritus mineralis.” Joseph Black (1755) observed that this “fixed air” combines with alkalis and earths and increases their weight. Lavoisier (1775) proved this gas to be composed of carbon and oxygen.

Carbonic acid gas is a regular constituent of the atmosphere, in which it is present to the extent of .04 or .05 per cent. by volume or about .06 per cent. by weight. In certain localities it issues from fissures in considerable quantity; it is a product of respiration of animal life and of alcoholic fermentation, exists in combination in many minerals, and is formed on the complete combustion of carbon or organic compounds in the presence of an excess of oxygen; diamond and graphite require a high heat for their combustion. Many organic compounds are readily oxidized at the ordinary temperature by chromic or permanganic acid, with the production of carbonic acid gas. But the best sources for preparing carbonic acid in a pure state are whiting, marble-dust, or similar native carbonates, which are decomposed by dilute sulphuric acid in an apparatus provided with a stirrer to prevent the sulphate of calcium formed from enveloping the undecomposed carbonate. On a small scale, and for obtaining a uniform current of carbonic acid gas, fragments of marble and diluted hydrochloric acid are used, whereby calcium chloride is formed, together with some water, and remains in solution. $\text{CaCO}_3 + 2\text{HCl}$ yields $\text{CaCl}_2 + \text{H}_2\text{O} + \text{CO}_2$. Should the gas possess a disagreeable odor, it may be deprived of it, according to Stenhouse, by passing it over granular charcoal, or, according to Hager (1868), by conducting it successively through solutions of ferric sulphate, sodium carbonate, permanganate of potassium, and water, by which treatment it is freed from sulphuretted hydrogen and hydrocarbons.

A cheap source of carbonic acid is sodium bicarbonate, which yields about half its weight of the gas, and when decomposed by sulphuric acid gradually added will, in addition, produce 15 parts of crystallized sodium sulphate for every 4 parts of the bicarbonate used.

Properties.—Carbonic acid—or, more properly, carbonic anhydride—is a colorless, unflammable gas, which has a slight pungent odor and pricking acidulous taste, colors moist litmus-paper transiently red, and does not support combustion. It is heavier than atmospheric air, its specific gravity at 0° C. being 1.524 as compared with atmospheric air, and 1 liter of it weighing 1.967 Gm. By pressure it is converted into a very mobile colorless liquid, which is lighter than water, and on the removal of the pressure boils rapidly, and is partly converted into white flakes of solid carbonic anhydride. It dissolves at 15° C. (59° F.) in an equal volume of water, and is more soluble in alcohol, absolute alcohol of 15° C. dissolving 3 volumes of the gas, which is partly

expelled on dilution with water. It unites with most of the basic hydrates, forming salts which, with the exception of the alkaline carbonates, are insoluble in water, but dissolve to a slight extent in carbonic acid water and are decomposed by all mineral and most organic acids. Carbonic acid is bibasic; all the acid carbonates (bicarbonates) are decomposed by heat, carbonic anhydride being evolved.

Pharmaceutical Uses.—In pharmacy carbonic anhydride is almost exclusively employed in the preparation of carbonic acid water.

Aqua acidi carbonici, U. S. 1870; *Aqua acidula simplicior*, F. Cod.; *Aqua carbonica*; *Carbonic acid water*, E.; *Eau gazeuse simple*, Fr.; *Kohlensäure-Wasser*, *Brausewasser*, G.

This water is very extensively prepared in the United States and sold under the names of *soda-water* and *mineral-water*. Several apparatus have been constructed and patented for the convenient preparation of carbonic acid gas and for charging the water with this gas under pressure. They consist of a generator, a strong copper vessel into which the powdered marble, whiting, or sodium bicarbonate is introduced with some water, and which connects with another copper vessel containing the sulphuric acid, which is admitted in small quantities. The gas is first passed through a vessel containing water, to deprive it of impurities, and then to the bottom of the fountain, as the receiving vessel is called, containing the requisite quantity of water. The fountains are made either of cast iron, well protected on the inside by enamel, or of copper lined with block-tin; or stoneware fountains, secured by iron bands, are employed. The water, which is usually charged with from eight to ten times its volume of carbonic acid gas, is drawn off through block-tin pipes, which pass through a chamber containing ice.

Carbonic acid water has an agreeable acidulous and refreshing taste, and effervesces strongly. It produces white precipitates with lime- and baryta-water, and acts upon iron, lead, and copper, which metals are gradually dissolved; tin and silver are less affected; hence the importance of preventing the water from coming in contact with other metals except the last two mentioned. It should not be discolored by sulphuretted hydrogen or ammonia, and yields no precipitate with sulphate of sodium or with ferrocyanide of potassium.

Medical History.—The ancient practice of burning aromatic herbs, and conveying the fumes by means of tubes and appropriate apparatus into the vagina, is, in reality, an example of treatment by carbonic acid, for this gas is the chief product of the combustion of such substances. It is probable that from a remote period the anti-emetic action of natural mineral waters impregnated with carbonic acid was recognized. It is certain that more than two hundred years ago the effervescing draught of Riverius, which owes its virtues chiefly to this gas, was used for the same purpose, and so continues to be employed at the present time. After Priestley had isolated the gas, it was speedily introduced into medicine by the English physicians of the last quarter of the eighteenth century as a remedy for the low forms of fever called "putrid," and its use to check or prevent vomiting became general. It was also extensively employed by inhalation, and, like other new medicines, was proclaimed by zealous and incautious physicians to be a specific for nearly every disease, including pulmonary consumption.

Physiological Action.—*On Animals:* Dogs obliged to breathe a mixture of 1 part of carbonic acid with 9 parts of atmospheric air are thrown into an anæsthetic sleep, which leaves no ill effects behind: when the proportion of the former gas is increased to one-fifth, one-fourth, or one-third, the effects are more marked, muscular resolution is more complete, and when the largest proportion is used the blood in the arteries assumes a dull hue. When the gases are given in equal proportions, and until death ensues, the animal urinates, its pulse grows frequent, the breathing labored, and the surface of a wound livid; after which the respiration fails, the heart beats feebly, and complete muscular relaxation, interrupted by slight spasms, precedes death. The blood is found very dark; the heart contains but little of it, and without clots; the lungs are engorged; the bronchia are filled with bloody froth, and their vesicular structure presents many apoplectic infarctions. Finally, when the proportion of carbonic acid to air is as 3 to 1, the first effect is convulsion, followed by complete anæsthesia even of exposed nervous trunks, and slowness of the pulse; yet, if the inhalation is not continued, the animal revives. If, on the other hand, it is urged to a fatal result, death occurs as in the previous experiment, and the same lesions are found, except that the heart as well as the lungs is gorged with blood (Demarquay). It would appear that the gas has no direct influence upon the blood, and that the dark color acquired by this fluid is due to an arrest of respiration depending upon the action of the gas upon the brain and medulla oblongata. When it is slowly administered, and death is thereby retarded, the temperature of the body falls,

and sugar is found in the urine. The respiration of pure carbonic acid is impossible, since an exchange of gases, which is the essence of the respiratory act, can no more take place in this gas than it can in water, and death by asphyxia is the immediate result.

On Man: Sufficiently diluted with atmospheric air, carbonic acid gas is more or less respirable. In the proportion of one-half or more its inhalation causes a prickling in the nostrils and larynx more agreeable than otherwise, together with a sense of constriction and oppression in the chest, headache, giddiness, and ringing in the ears, followed by unconsciousness, dilatation of the pupils, sometimes congestion of the face, and, if relief be not at hand, fatal congestion of the brain. Even when the proportion of the gas is smaller, it causes more or less giddiness, constriction of the præcordia, and feebleness of the legs; the pulse, which at first is fuller and stronger, becomes feebler, the respiration is slow and shallow, and the mind and senses are more or less confused. In moderate or medicinal portions the primary action of the gas is sensibly stimulant, but secondarily it inclines to repose and sleep. In such experiments on man no evidence has been given of the anæsthetic influence of the gas, and it is probably not developed until a state of dangerous narcotism is induced. Some cases of death are recorded from the emanations of certain fissures, like the Grotto del Cane. In the case of a young man who died in this manner in the Grotto of Pymont the appearance of the corpse was that of a person in natural sleep. There was no congestion of the face, the pupils were dilated and the cornea brilliant; the brain was deeply congested, the lungs distended and not engorged; the jugular veins were also distended, but the heart contained very little blood. These conditions are as opposite as possible to those induced by asphyxia by the fumes of charcoal, and do not perfectly harmonize with those produced in animals, as described above. When the body except the head is immersed in a vessel of this gas, a sense of heat and prickling is experienced over the entire surface, but especially where the integument is delicate, and is accompanied with perspiration and redness. The pulse, according to some, is quickened, according to others is retarded. If the operation is sustained for half an hour, the head throbs and the senses are dulled; the respiration is labored, and borborygmi and colic occur. When a limb is exposed for some time to the action of the gas, the sensibility of the skin is obtunded; and if the exposed surface is a wound, it becomes the seat of smarting pain, followed by impaired sensibility, but the tissues grow redder. Brown-Séquard has shown that in animals the sensibility and reflex excitability of the larynx can be completely obtunded by this gas. Water impregnated with it causes a prickling sensation in the mouth, fauces, and nostrils, a sense of warmth in the stomach, and a transient cerebral excitement. It also appears to quench thirst far better than water alone. The gas liberated in the stomach is mainly discharged by eructation, but it seems to stimulate the gastric secretions and promote digestion. Habitually used, carbonated water becomes laxative. It also increases the urine, and is said to augment the oxalates and carbonates in that secretion.

Medical Uses.—The administration of carbonic acid gas by inhalation was at one time in vogue as a remedy for pulmonary *phthisis*, *chronic bronchitis*, and *laryngeal diseases*. Many leading English physicians vouched for its efficacy, and very possibly it may have palliated the cough and lessened the secretions in these affections; but much more efficient remedies have supplanted it. The same remark may be made respecting *asthma*. One of the most useful internal applications of this gas is to allay *vomiting* caused by irritability of the stomach. It often subdues this symptom promptly when given in the effervescing draught, in plain carbonated water, in champagne wine, or in still and dry white wines mixed with such water. The liquid should always be cold, and, if possible, iced. Several cases of *intestinal obstruction*, the precise nature of which does not appear, have been relieved by allowing carbonic acid water to escape from a siphon bottle through a long tube into the bowel. In one case relief was obtained by injecting successively the two ingredients of a “soda-powder” in solution, and in another by allowing the contents of a “siphon-bottle” of carbonated water to escape into the bowel (*Med. News*, xl. 597).

The most important uses of carbonic acid are those in which it is applied in water as a local stimulant. There can be no doubt that in its combined stimulant and anæsthetic properties reside the virtues which have long been recognized in the yeast poultice and other fermenting cataplasms applied to *ulcers*, simple, cancerous, etc. Injections of carbonated water have been found to afford great relief in many cases of *cancer* of the uterus, rectum, and other parts; and a similar result has been obtained by maintaining a current of the gas in contact with the uterus in ulcerated states of that organ, and also in certain cases of uterine *leucorrhœa*, *dysmenorrhœa*, *amenorrhœa*, etc. The carbonic acid gas douche has also been successfully employed to induce *premature labor*. Whether

it be owing to a stimulant action or to a slightly anæsthetic influence, carbonic acid water certainly aids in causing the stomach to retain what it might otherwise reject, as is shown in the familiar and popular habit of using it as a vehicle for magnesia and various saline medicines, and in febrile and other diseases attended with *nausea* or *vomiting*. It possibly promotes the diaphoretic action of the effervescing draught, and is perhaps more diuretic than simple water. Taken with the food, it forms one of the most efficient remedies for *flatulence*.

The treatment of poisoning by this gas consists in measures adapted to expel it from the lungs, to stimulate the nervous system, and to introduce atmospheric air or oxygen in its place. For the first purpose artificial respiration by mechanical and electrical means is indicated; for the second, active stimulation of the skin mechanically by warmth and by irritants, and the injection of a strong infusion of coffee into the rectum; if any oxygen gas can be procured, it may be forced through a laryngeal tube into the lungs.

ACIDUM CHROMICUM, U. S., P. G.—CHROMIC ACID.

Chromic anhydride, E.; *Acide chromique*, Fr.; *Chromsäure*, G.

Formula CrO_3 . Molecular weight 100.4.

Preparation.—This acid was discovered by Vauquelin (1797). Its preparation by means of sulphuric acid was first suggested by Fritzsche (1839), and is conveniently accomplished, according to Warrington, by pouring 3 measures of concentrated sulphuric acid into 2 measures of a cold saturated solution of bichromate of potassium in water, the reaction occurring as follows: $\text{K}_2\text{Cr}_2\text{O}_7 + 2\text{H}_2\text{SO}_4 = 2\text{CrO}_3 + 2\text{KHSO}_4 + \text{H}_2\text{O}$. More economical is the process of Bolley, modified by Traube (1848), which is as follows: 2 parts of potassium bichromate are dissolved with the aid of heat in 7 parts of sulphuric acid and 5 parts of water; the solution is set aside for a day, decanted from the crystals of acid potassium sulphate, and mixed with 8 parts of sulphuric acid. The French Codex gives the following directions: Dissolve, with the aid of heat, 1 part of bichromate of potassium in 10 parts of water; allow the solution to cool to 25°C . (77°F .), and add in small portions and with continued stirring 20 parts of sulphuric acid, spec. grav. 1.84; set the mixture aside for 24 hours, and then decant the liquid. Collect the crystals in a glass funnel, the neck of which is imperfectly closed with fragments of glass; drain and finally dry the acid by keeping it for two days upon porous tiles in a drying closet at 35°C . (95°F .). Bunsen (1868) employs 1 part of the bichromate and 10 parts each of water and sulphuric acid; the crystals are collected upon a filter of asbestos or pumice-stone in a cylindrical vessel, and are washed, under an air-pump, with nitric acid, which must be free from lower oxides, until free from adhering sulphuric acid. In 1881 the United States imported 124 pounds of chromic acid.

Properties.—Thus obtained, it occurs in needles or quadrangular prisms of a deep crimson-red color, inodorous, deliquescent, and very soluble in water; the concentrated solution is of a red-brown color, which changes to orange-yellow on being diluted; the dilute solution reddens blue litmus-paper and bleaches it on drying. Gradually heated, the crystals assume a blackish-brown color, and at a temperature of 180° to 190°C . (356° to 374°F .) fuse into a reddish-brown liquid, which on cooling becomes a dark-red, opaque, brittle mass. At about 250°C . (482°F .) the acid is decomposed into oxygen and dark-green chromic oxide. If strong alcohol is dropped upon the acid, a vigorous action takes place, accompanied with increase of temperature and ignition of the alcohol. A rapid ignition is likewise observed with benzol; but ether which is free from both alcohol and water dissolves this compound, and on spontaneous evaporation yields it again in minute crystals. Chromic acid dissolved in diluted alcohol is gradually deoxidized at the ordinary temperature, the alcohol being converted into aldehyd and acetic acid. Reduction takes place also in the presence of arsenious, sulphurous, and hydro-sulphuric acids, and of organic compounds and deoxidizing agents generally. When heated with hydrochloric acid, chlorine and green chromic chloride are produced.

Chromic acid contains no water of crystallization; its salts have mostly a yellow or yellowish-red color; those of the alkalis and of magnesium are soluble in water; all others dissolve in nitric acid.

Tests.—Sulphuric acid and potassium salts are usually present in small quantity. The former is detected by adding to its hot aqueous solution some hydrochloric acid, deoxidizing with alcohol until the liquid becomes green, and then adding chloride of barium, when a white precipitate will be produced; the latter, by concentrating the green

solution as much as possible, and adding a concentrated solution of tartaric acid, when crystalline bitartrate of potassium will be separated; or the chromic acid is, by ignition, converted into chromic oxide, and this is treated with water, which will dissolve potassium sulphate and chromate if present. The Pharmacopœia disregards the presence of the salts, and directs testing for sulphuric acid by barium chloride in a 1 per cent. solution of chromic acid strongly acidulated with hydrochloric acid, when merely a white turbidity should be produced.

Allied Acid.—ACIDUM PEROSMICUM s. OSMICUM; Osmic acid, osmium tetroxide, OsO_4 ; mol. weight, 262.5. It is formed on heating metallic osmium in a current of oxygen, and is obtained in the preparation of iridium and allied metals as a by-product, to be purified by fractional distillation. The sublimed oxide is in colorless, glossy needles; after fusion it is a white, translucent, crystalline mass, which is pliable at about 38°C . (100°F .) and near the boiling-point of water melts and volatilizes without decomposition; at ordinary temperatures it sublimes slowly. It has a powerfully pungent and irritating odor, somewhat resembling that of chlorine, and a caustic taste. It dissolves slowly, but in considerable proportion, in water, forming a colorless acid solution, which by sulphurous acid is colored yellow, then red, green, and finally blue; the solutions in alkalis are orange-red, and on heating give off oxygen and osmium tetroxide, leaving an alkali osmite. It liberates iodine from iodides, is reduced from its solution by silver and other metals, and oxidizes organic compounds.

Pharmaceutical Uses.—In prescription chromic acid should never be combined with organic or deoxidizing mineral compounds. In liquid form it should be dissolved in distilled water. The solution of the French Codex is made of equal parts of chromic acid and distilled water, and has a specific gravity of 1.47.

Physiological Action.—Chromic acid is one of the most energetic of caustics. At a moderately high temperature it rapidly dissolves all animal tissues immersed in it, including even hair, bones, and teeth. When at ordinary temperatures it is applied to the skin, it renders that tissue moist, and then brown, and finally black, forming an eschar of 1 or 2 lines in thickness, which separates within 48 hours, leaving a granulating surface which tends to heal rapidly. According to the degree of its concentration it may be deeply or superficially caustic, or merely astringent and drying. When pure it is said not to be severely painful, but it becomes so when it is contaminated with sulphuric acid or arsenic.

Medical Uses.—Among caustics none is superior or even equal to chromic acid for the purpose of removing certain excrescences from the skin and the mucous membranes. *Condylomata*, warty growths, especially such as occupy a considerable surface, *vegetations* of the genital (and especially of the female genital) organs, are promptly destroyed by a solution of 1 part of it to 1 of water, and with far less pain than is inflicted by caustic potassa. Chromic acid is one of the best applications that can be made to the *gums* when they tend to ulceration and retraction in scrofulous patients and after mercurial salivation, as well as to scrofulous and syphilitic ulcers of the *pharynx* and the mouth. Similar affections of the interior of the *larynx*, œdema of this organ, and especially tumors of the vocal cords and adjacent parts, have been cured by skilful cauterization with chromic acid, aided by the laryngoscope. A mild solution may at first be used, but subsequently one containing 1 part of the acid to 8 of water, or even of twice that strength, may be applied by means of a small, fine, and compact piece of sponge. The solution of 10 grains of chromic acid in an ounce of water, recommended by Paget for ulceration of the *tongue*, has been similarly applied, and with striking success, to secondary syphilitic affections of the organ (ulcers, mucous tubercles, condylomata), but fails in the tertiary lesions. Various chronic affections of the skin, as *tinea*, *syphilis*, and *lupus*, are appropriate for its use. It is an efficient remedy for *condylomata*. Its prompt and powerful action renders it one of the best applications for arresting surface *hæmorrhage*, and in a diluted state it is a valuable stimulant for indolent *ulcers*. Syphilitic and even tuberculous ulcers of the *pharynx* have been treated in this manner; and so has granular inflammation of this part, and *conjunctivitis* of a similar character. Uterine *hæmorrhage*, depending upon laxity of the tissues of the organ, has been successfully treated by the insufflation of a few drops of the acid. In the treatment of *uterine leucorrhœa* no other caustic is more efficient than this; but it should be introduced very cautiously by means of a syringe having a lateral opening near the end of its tube, and the superfluous liquid should be withdrawn when the syringe is removed. The previous dilatation of the neck of the uterus facilitates the operation and the cure. If the acid is too strong, it may give rise to permanent stricture of the canal of the cervix. This tendency to contraction of the tissues to which it is applied has sometimes been taken advantage of to relieve *incon-*

tinence of urine in the female due to relaxation of the urethra. When this infirmity is connected with *irritable tumor* of the urethra, the acid will sometimes prevent the necessity of employing cutting instruments. In applying this powerful caustic in a concentrated state—the deliquescent crystals, for instance—great care should be taken to protect the adjacent sound tissues by means of adhesive plaster or a simple ointment, and all superfluous acid should be immediately removed with a pledget of moist lint. The pure acid should be applied by means of a wooden, glass, or porcelain rod or spatula. Diluted solutions may be used with a camel's-hair brush, which immediately afterward should be well washed with water. Chromic acid ought not be dissolved in glycerin, for if the mixture be made rapidly ignition occurs with explosion.

OSMIC ACID was used by Winiwarter in a 1 per cent. solution as an injection into a large *sarcomatous tumor* seated upon the neck. About 3 drops of the solution were injected daily for a fortnight, and at the end of that time the substance of the tumor had broken down and was evacuated. Similar treatment with like results was successful in other cases (*Med. News*, xlii. 495). But the same treatment when employed by Pfeilsticker entirely failed, and by causing adhesion of the tumors to adjacent parts rendered their subsequent removal by an operation more difficult (*Med. Record*, xxiv. 159).

ACIDUM CITRICUM, U. S., Br., P. G.—CITRIC ACID.

Acidum citri s. limonum s. limonorum.—*Acide citrique, Acide du citron*, Fr.; *Citronensäure*, G.

Formula $\text{H}_2\text{O} \cdot \text{H}_3\text{C}_6\text{H}_5\text{O}_7 = \text{C}_6\text{H}_4(\text{OH})(\text{COOH})_3 \cdot \text{H}_2\text{O}$. Molecular weight 210.

Origin.—The acid properties of lemon-juice were observed at an early period, but the distinction of the acid from other vegetable acids was not recognized until Retzius (1776) proved it to differ both from tartaric and acetic acids. Scheele (1784) obtained citric acid in crystals. It was prepared artificially in 1880 by Grimaux and Adam from glycerin, and perhaps also by Andreoni and Kekulé from malic acid. Citric acid occurs in a large number of plants, either in the free state or combined with potassium or calcium, and frequently associated with malic acid. It has been found in the rhizomes of *Asarum europæum* and *Sanguinaria canadensis*, in the tubers of dahlia and Jerusalem artichoke, in the herb of lactuca and tobacco, and in many fruits, such as capsicums, tomatoes, tamarinds, cherries, gooseberries, raspberries, whortleberries, cranberries, blackberries, strawberries, etc. It occurs most abundantly, however, and as free acid, in the fruits of the *Aurantiaceæ*, and is prepared in large quantity from the juice of the lemon and the lime.

Preparation.—Citric acid is manufactured in England on a large scale from lemon- and lime-juice, which are obtained from Italy. The juice is exported, either in its natural condition or considerably concentrated by evaporation, or else in the form of a crystalline powder as citrate of calcium or magnesium. Recently, Messrs. Powers & Weightman have undertaken to prepare it in this country from sour oranges raised in Florida. The juice is clarified by ebullition, or, if obtained from unsound fruits, by allowing it to undergo the vinous fermentation. After decantation and straining an excess of chalk (carbonate of calcium) is added, and finally some milk of lime. The citrate of calcium thus formed being less soluble in hot than in cold water, the mixture is heated to boiling, and while hot the clear liquid is drawn off from the precipitated citrate of calcium, which is washed with boiling water for the purpose of removing all the extractive matter. The calcium citrate is now decomposed by diluted sulphuric acid in such a proportion as to form sulphate of calcium and to leave a little sulphuric acid in excess. 10 parts of citrate of calcium require about 9 parts of sulphuric acid diluted with from 50 to 60 parts of water. The solution of citric acid is drawn off from the precipitated sulphate of calcium, and the latter washed with very cold or with boiling water, in which gypsum is less soluble than in water of a medium temperature. The liquid, with the washings, is evaporated by steam-heat to a syrupy consistence, and then allowed to crystallize in suitable tanks lined with lead. The presence of a little sulphuric acid appears to favor crystallization, which is prevented or considerably retarded by acid citrate of calcium. The crystals are redissolved in a small quantity of water, and the solution is treated with animal charcoal, and then evaporated to crystallize. These directions agree in the main with those given in the British Pharmacopœia. Citric acid may be prepared by this process from the juice of other acidulous fruits; Græger (1873) described the manipulations necessary to obtain it advantageously from whortleberries. The importations of

citric acid amounted in 1867 to nearly 83,000 pounds, and at present average about 33,000 pounds annually.

Properties.—Citric acid crystallizes in colorless rhombic prisms which have an agreeable acid taste. It dissolves in three-fourths of its weight of cold, and in half its weight of boiling, water, in 1.15 parts of 80 per cent. alcohol at 15° C. (Schiff), in 1.3 parts of absolute alcohol, and in 48 parts of pure ether (insoluble in pure ether, *Br.*). It is also soluble in methylic and amylic alcohols and glycerin, and is freely soluble in hot creasote, but insoluble in chloroform and in hydrocarbons, except in the presence of alcohol. When a solution is made by dissolving 34 grains of the crystals in 1 ounce of water, it resembles lemon-juice in strength and in the nature of its acid properties, and, like lemon-juice, it undergoes decomposition, acetic acid being among the products, and becomes mouldy by keeping. The crystals are permanent in dry air, but at a somewhat elevated temperature slowly part with their water of crystallization, and in a damp atmosphere they become moist and gradually deliquesce. They melt at 100° C. (212° F.) in their water of crystallization; the anhydrous acid fuses at 150° C. (302° F.), and at a higher heat is decomposed, evolving empyreumatic vapors of an odor resembling that of burnt sugar, and producing a bulky charcoal, which is finally burned without leaving any residue or not more than .05 per cent. of ash.—*U. S.*

Citric acid is a tribasic acid having the formula $H_3C_6H_5O_7$, or, as met with in the crystallized condition, $H_3C_6H_5O_7 + H_2O$. The water of crystallization, amounting to 8.6 per cent., is expelled at 100° C., and at 155° C. (311° F.) another molecule of water is given off, *aconitic acid*, $H_3C_6H_3O_6$, remaining behind, which is identical with the acids that have been isolated from aconite, yarrow, and other plants. Like citric acid, it forms three series of salts, either 1, 2, or 3 atoms of hydrogen being replaceable by a basylous radical.

The citrates of the alkalies are all soluble in water; the neutral citrates of the heavy metals are mostly insoluble in water, but dissolve in nitric, and many also in citric, acid. Ferric and aluminium citrates are not precipitated by alkalies. That the calcium citrate is soluble in cold and insoluble in hot water has been already mentioned. If lime-water is not completely neutralized by solution of citric acid, no precipitate will occur until the liquid is heated to boiling. 70 grains of citric acid dissolved in distilled water are neutralized by 1000 grain-measures of the volumetric solution of soda (*Br.*), or 3.5 Gm. of the acid by 50 Ccm. of the soda solution (*U. S.*).

Impurities and Adulterations.—The impurities which may be present in citric acid in consequence of carelessness in its manufacture may be sulphuric acid, calcium, iron, lead, and copper. Minute fragments of metallic lead are occasionally observed adhering to some of the crystals. Sulphuric acid is readily detected in the aqueous solution of citric acid by the white precipitate occurring with chloride of barium; iron, by the blue color occasioned by ferrocyanide of potassium; and lead and copper, by the black coloration or precipitate resulting from sulphuretted hydrogen. For the detection of calcium it is advisable to neutralize the citric acid solution with ammonia, then to acidulate with acetic acid, and add oxalate of ammonium, when a white precipitate of oxalate of calcium will appear. Or the mineral impurities may be tested for in the ash after dissolving it in a little dilute nitric acid.

Tartaric acid is occasionally used as an adulteration, and oxalic acid and various crystallized salts are said to have been employed for the same purpose. Such frauds are usually accomplished by mixing the foreign compounds in a crystalline form with the acid, and it is therefore necessary to employ a larger quantity (say several ounces) of the large and small crystals, to be triturated in a mortar into powder. Many of the salts will be found to be insoluble in alcohol, and may thus be detected, or by the residue left on incinerating a portion of the powder upon platinum-foil. The aqueous solution of the powder is neutralized with ammonia, and then acidulated with acetic acid. Upon adding chloride of calcium, oxalic acid, if present, will be precipitated as white oxalate of calcium. The clear filtrate, neutralized with ammonia, will deposit in the cold white tartrate of calcium if tartaric acid be present, and the filtrate from it will, on boiling, throw down citrate of calcium. On dissolving some of the powder in diluted alcohol, and adding a concentrated solution of acetate of potassium, tartaric acid will yield a white crystalline

FIG. 6.

Crystal of Citric Acid.

precipitate of bitartrate of potassium. Oxalic acid, if present in sufficient quantity, will likewise cause a precipitate with this test. Or a number of crystals of different sizes are placed upon a glass plate in a little potassa solution, or preferably a strong solution of potassium acetate: the crystals of citric acid will remain transparent, while the crystals of tartaric acid will become opaque, in consequence of the formation of bitartrate of potassium. Cailletet (1877) observed the slow action in the cold of potassium bichromate upon citric acid, and recommends testing for tartaric acid by adding 1 Gm. of the suspected acid in powder to 10 Cem. of a cold saturated solution of the bichromate, and stirring with a glass rod. Pure citric acid does not change the orange color of this solution in 10 minutes; but in the presence of 1 per cent. of tartaric acid the mixture will have acquired, in the time mentioned, the color of infusion of coffee, and with 5 per cent. of tartaric acid it will have become blackish-brown.

Pharmaceutical Uses.—*PULVIS AD LIMONADUM.* Triturate thoroughly white sugar 120 Gm., citric acid 10 Gm., oil of lemon 1 drop.—*P. G.* 1872.

Off. Prep.—Ferri et ammon. citras, Ferri et quiniæ citras, *Br.*; Ferri pyrophosphas, *U. S.*; Liquor ammonii citr., Liq. bismuthi et ammon. citr., *Br.*; Liq. ferri citr., Liq. potass. citr., *U. S.*; Liq. magnes. citr., Lith. citras, Potass. citras, *U. S.*, *Br.*; Sodæ citro-tartaras effervescens, *Br.*; Syrupus acidi citrici, *U. S.*

Physiological Action.—Experiments with citric acid on cats, rabbits, and other animals illustrate the necessity of caution in founding opinions upon such grounds exclusively. To these creatures citric acid is a powerful poison, lowering sensibility and the heart's force and producing violent tetanic spasms. That these phenomena are not occasioned by gastric irritation is proved by the absence after death of all inflammatory lesions of the stomach. The blood appears to have been unusually liquid. In man, on the other hand, not only are no spasmodic or other alarming symptoms produced by citric acid, but it does not diminish the coagulability of the blood; so far from this, indeed, in the form of lemon-juice it is of all agents the most efficient in correcting that incoagulability of the blood which is characteristic of scurvy. When largely administered it increases the acidity of the urine, causing a deposit of free uric acid. According to Langfeldt, 1 part of this acid in 2000 parts of water is sufficient to destroy all the animalculæ in the liquid that are not protected by a thick epithelial covering. Citric acid used habitually is very apt to corrode the teeth.

Medical Uses.—The most useful application of lemon-juice and citric acid is to prevent and cure *scurvy*, a purpose which long and extensive experience has proved them admirably fitted to fulfil. Of the two, lemon-juice is by far the most efficacious, and the opinion that its efficiency is not due to the acid alone is shown not only by this comparison, but also by the well-known fact that many fresh vegetables are endowed with a similar power. The use of lemon-juice in the treatment of acute articular *rheumatism* was at one time confidently relied on, but is no longer in vogue, and the article is employed only as a means of assuaging the thirst and reducing the febrile heat in that disease, as well as in various other diseases of which *fever* is a prominent symptom. A physician has gone so far as to assert that if a fresh lemon is cut into pieces and boiled in 3 cups of water until reduced to one-third, the strained liquor will cure malarial affections as well as quinine, or still better (*Bull. de thérap.*, cv. 76). Such credulity is worthier of the infancy of medicine than of the nineteenth century. Citric acid may be used with some advantage during *hæmorrhage*, but its direct effect upon this symptom is slight, indeed, when compared with that of the mineral acids. The practice of arresting post-partum hæmorrhage by squeezing out the juice of a cut lemon within the cavity of the uterus deserves attention, less from the coagulating action of the acid than from the stimulation exerted by it upon the interior of the womb, which is at the same time mechanically irritated. Lemon-juice is of some advantage in *jaundice* depending upon congestion of the liver, and may be employed as an antidote to alkaline and narcotic poisons. It forms an agreeable application in *diphtheritic angina* and in *gangrenous sore mouth*, and has been used with striking advantage to relieve *pruritus* of the genital organs.

ACIDUM FORMICICUM, *P. G.*—FORMIC ACID.

Acidum formicarum s. formicum.—*Acide formique*, Fr.; *Ameisensäure*, G.
Formula $\text{HCHO}_2 = \text{HCOOH}$. Molecular weight 46.

Origin and Preparation.—In the beginning of the sixteenth century Otto Brunfels observed the acid reaction upon blue vegetable colors of the air in the nest of the wood-ant (*Formica rufa*, *Linneë*). By distilling ants John Wray (1670) obtained an acid

liquid possessing properties similar to those of vinegar. Andrew Marggraf (1749) proved this acid to be not identical with acetic acid. Scheele (1774) obtained the acid artificially from gum and sugar, but considered it to be acetic acid, a view disproved by Doebereiner (1822).

Formic acid is found in ants, in some caterpillars, old oil of turpentine, nettles and other plants, and is formed by the oxidation of methylic alcohol; by the action of black oxide of manganese and sulphuric acid or of chlorinated lime upon sugar, starch, and other carbohydrates and allied compounds; by the decomposition of chloral hydrate and of chloroform by means of potassa; and by other reactions. Lorin (1865) observed that in the presence of glycerin and a little water oxalic acid is readily decomposed into formic acid and carbonic acid gas; $C_2H_2O_4$ yields $CH_2O_2 + CO_2$. Berthelot prepares it by heating in a retort 10 parts each of oxalic acid and glycerin and 1 or 2 parts of water to a little over $100^\circ C.$ ($212^\circ F.$); the oxalic acid is preferably added in portions of 2 or 3 parts. After about 12 hours the decomposition is complete, and the contents of the retort are repeatedly diluted with 5 parts of water and distilled; the residue in the retort is preserved for a future operation, while the distillate is neutralized with sodium carbonate and evaporated to dryness by means of a water-bath; 100 parts of dry sodium formate require 75 to 76 parts of sulphuric acid for decomposition, which may be diluted with water according to the strength of formic acid desired; the latter is obtained by distillation.

Properties.—Anhydrous formic acid is a colorless liquid of 1.235 sp. gr., crystallizing below the freezing-point of water, boiling near $99^\circ C.$ ($210^\circ F.$), having a pungent acid odor, and producing a burning sensation when applied to the skin. Its vapor is inflammable and burns with a blue flame. The acid is soluble in all proportions of water, alcohol, and glycerin. According to Roscoe (1862), the boiling-point of aqueous formic acid gradually rises until the temperature $107.2^\circ C.$ ($225^\circ F.$) is reached, when the boiling-point remains constant and the distillate contains 77.5 per cent. of formic acid. Its salts are soluble in water, and impart to solutions of ferric salts a dark brownish-red color which disappears on the addition of hydrochloric acid. When heated with solutions of the salts of mercury, silver, gold, and allied metals, these are reduced to the metallic state.

The medicinal acid has the specific gravity 1.060 to 1.063, and yields with subacetate of lead a white crystalline precipitate. 10 Gm. of it neutralize 54.35 Cem. of normal potassa solution, indicating 25 per cent. of absolute formic acid. If diluted with 5 parts of water, it should not be precipitated by silver nitrate (hydrochloric acid), nor be colored by sulphuretted hydrogen (metals), nor, after neutralization with ammonia, be precipitated by calcium chloride. On heating for 10 minutes 1 Gm. of the acid, 5 Gm. of water, and 1 Gm. of yellow mercuric oxide, the filtrate should have a neutral reaction (absence of other acids).—*P. G.*

SPIRITUS FORMICARUM, P. G. Mix alcohol 70 parts, water 26 parts, and formic acid 4 parts. It is a colorless liquid of an acid reaction, which, when mixed with one-twentieth of its weight of solution of subacetate of lead, becomes filled with feathery crystals.

AMMONII FORMIAS, NH_4CHO_2 , is obtained by neutralizing the acid with ammonia and evaporating to crystallization. It is in colorless prisms of a refreshing pungent taste, fuses at about $100^\circ C.$ ($212^\circ F.$), and when rapidly heated to $180^\circ C.$ ($356^\circ F.$) is decomposed into hydrocyanic acid and water; NH_4CHO_2 yields $HCNO + 2H_2O$.

Physiological Action.—The experiments of Wolff show that formic acid is not an antiseptic, is only a feeble antifermentative, and is of no value as an antiputrid agent. Upon the skin this acid acts as an irritant and vesicant, and if its contact is prolonged it may produce a slough. Administered to rabbits, it produces inflammation of the gastrointestinal mucous membrane and a discharge of bloody urine. 2 drachms in a pint of water occasioned excitement of the circulation, increased heat, hurried breathing, and diuresis in a horse. In man similar effects have been noted. In gouty patients it is reported to have caused a discharge of muddy and ill-smelling urine. According to Arloing, small doses of *formiate of sodium* increase the number and depth of respirations and cause irregular breathing in the dog and horse. Large doses render it rapid and shallow, and very large doses suspend it, the temperature meanwhile falling 2° or $3^\circ C.$ Direct injection of a large dose of the salt into the right ventricle is followed by slower or suspended movements of the heart.

Medical Uses.—Formic acid was at one time used internally to stimulate, as ammonia is generally employed, and externally, like that irritant, for the relief of local *neuralgic* and *rheumatic* pains, etc. *Spiritus formicarum* (P. G.) is prescribed in doses of from 20 to 60 drops (Gm. 1.30–4.00). *Formiate of ammonia* has been used in chronic *paralysis* and in *epilepsy*, but uselessly. *Dose*, about 5 grains (Gm. 0.30).

ACIDUM GALLICUM, U. S., Br.—GALLIC ACID.

Triorybenzoic acid, Dioxy-salicylic acid.—*Acide gallique, Fr.; Gallussäure, G.*

Formula $C_7H_6O_3 \cdot H_2O = C_6H_4(OH)_3 \cdot COOH$. Molecular weight 188.

Origin.—Gallic acid is found in nutgalls, sumach, uva ursi, and in a number of other astringent plants. It was for a time confounded with tannin, but its distinction from this was recognized by Scheele (1785), who obtained it in a pure state. It is most advantageously prepared from galls by Scheele's process, as modified by Pelouze and Robiquet, for which the Pharmacopœia of 1870 gave the following directions:

Preparation.—Take of Nutgall in fine powder 36 troyounces; purified Animal Charcoal and Distilled Water, each a sufficient quantity. Mix the nutgall with sufficient distilled water to form a thin paste, and expose the mixture to the air, in a shallow glass or porcelain vessel, in a warm place for a month, occasionally stirring it with a glass rod, and adding from time to time sufficient distilled water to preserve the semifluid consistence. Then submit the paste to expression, and, rejecting the expressed liquid, boil the residue in 8 pints of distilled water for a few minutes, and filter, while hot, through purified animal charcoal. Set the liquid aside that crystals may form, and dry them on bibulous paper. If the crystals be not sufficiently free from color, they may be purified by dissolving them in boiling distilled water, filtering through a fresh portion of purified animal charcoal, and again crystallizing.

The process of the British Pharmacopœia is, with the following modifications, essentially the same: The coarsely-powdered galls and water are exposed for 6 weeks at a temperature of between 15° and 21° C. (60° and 70° F.); the mass is then boiled with more distilled water; the crystals formed in the strained liquid are strongly pressed between bibulous paper, and then recrystallized from boiling distilled water without the use of animal charcoal.

Other processes have from time to time been suggested, the most important of which are based upon the observation of Liebig that when boiled for some time with somewhat diluted sulphuric or hydrochloric acid or for a few seconds with potassa solution, tannin is converted into gallic acid.

The above directions are so clear that the preparation of gallic acid by them presents no difficulties, and the only additional precaution that deserves to be mentioned is the avoidance of its contact with iron and iron salts, which would impart to the acid a color difficult to remove. The conversion of the whole amount of tannin into gallic acid is readily proved by testing a small portion of the filtered liquid with solution of isinglass, which should cause no turbidity. The change takes place slowly at a low temperature; P. Weber (1880) found about 45° C. (113° F.) to be most suitable for the process given above. The yield must necessarily vary with the amount of tannin present in the galls.

Gallic acid has been obtained artificially by the action of alkalies upon diiodo- or dibromosalicylic acid (Lautemann, 1861), and upon bromdioxybenzoic or bromoprotocatechuic acid (Barth and Sennhofer, 1872).

Formation.—The conversion of tannin into gallic acid has been the subject of much controversy, involving numerous researches. It was at first supposed that gallic acid existed ready formed in galls; the experiments of Pelouze (1833) proved that most of it is formed from the tannin contained therein, and this conversion he supposed to be due to the oxidizing influence of oxygen, by which carbonic acid was eliminated. Robiquet (1837) found that the tannin of galls is converted into gallic acid without the admission of oxygen and without the evolution of gas. He ascribed this to the action of a ferment present in the galls, which was subsequently named *pectase*. Laroque's experiments (1841) supported this view. That the growth of mould upon the infusion of galls is without influence upon the production of gallic acid was proved by Winckler (1835). C. Wetherill (1847) advanced for the first time the opinion that gallic acid differs from tannin merely by containing additional water, and he was supported in this theory by the investigations of Mulder (1848). Meanwhile, Liebig had suggested that in the transformation of tannin into gallic acid a carbohydrate was liberated; and Strecker's experiments (1854) appeared to furnish conclusive proof that tannin is a glucoside, which on being boiled with diluted mineral acids yields theoretically 82.5 per cent. of gallic acid. The quantity obtained was, however, in excess of this figure, and Stenhouse, Knop, Rochleder, and others proved that gallic acid almost equalling the weight of tannin used could be thus obtained. Robiquet (1854) considered this result due to molecular change accompanied by hydration, whereby tannin is transformed into gallic acid just as cane-sugar under similar influences is transformed into grape-sugar. This view, however, did not

explain why, on the treatment of tannin with diluted acids, glucose was obtained in variable quantities. Hlasiwetz (1867) suggested that it probably was not a true glucoside, owing to the difficulty with which the glucose is obtained. The relation of the two compounds to each other appears to be finally settled by the researches of H. Schiff, Sac, and J. Löwe (1871 and 1872), according to which pure tannin is *digallic acid*, an anhydride of gallic acid, the conversion of the former into the latter occurring as follows: $C_{11}H_{10}O_9 + H_2O = 2C_6H_6O_5$; and the sugar observed in the preparation of gallic acid is referable to the glucose which naturally exists in galls, perhaps in combination with digallic acid, and from which tannin is with difficulty purified. Löwe prepared pure tannin from galls, and Schiff succeeded in converting gallic acid into tannin absolutely free from glucose.

Properties.—Gallic acid is in fine white or pale fawn-colored silky needles, which have a slightly acid and faint astringent taste, and are inodorous. It is soluble in 100 parts of cold and 3 parts of boiling water. The solution has an acid reaction, and gives no precipitate with ferrous sulphate. With ferric salts a bluish-black precipitate is obtained, which is easily soluble in acetic acid, and disappears on boiling. It is not precipitated by solution of gelatin or albumen except in the presence of gum, and yields no insoluble compounds with vegetable alkaloids. Gallic acid dissolves permanently in a solution of potassium citrate, to such an extent that, according to F. Long (1881), 15 grains of it, with 20 grains of the citrate, will yield a clear solution in 1 ounce of water. It dissolves at 15° C. in 2.6 parts of absolute alcohol, in 4.3 parts of 90 per cent. alcohol, and in 39 parts of pure ether (Bourgoin); it is also soluble in glycerin, and nearly insoluble in chloroform and benzin. At 100° C. (212° F.) it loses 9.5 per cent. of water of crystallization. Heated to between 200° and 215° C. (392° and 419° F.), or, according to Schiff (1879), to about 240° C. (464° F.), it melts, and then yields carbonic acid gas and a sublimate of pyrogallol = $C_6H_6O_3$, without leaving any residue.

Alkalies added to a solution of gallic acid rapidly color the liquid, which in the presence of very little potassa or soda gradually becomes green, but with an excess is at once yellow and turns red and brown; little ammonia causes a yellow, and an excess a reddish and red-brown, color. Alkaline carbonates produce similar colorations, but act less energetically; on the subsequent addition of hydrochloric acid the color is changed to red. Dudley (1879) observed that a dilute solution of ammonium picrate with excess of ammonia causes in solution of gallic acid a red color, rapidly changing to a beautiful green. Lime-water produces with gallic acid a flocculent precipitate, which turns rapidly blue and green, and is soluble in much lime-water with a pink color, and in excess of gallic acid with a brown color. Most of its salts, those with the alkalies excepted, are insoluble in water. When perfectly dry they keep unaltered, but in the presence of water, and particularly of alkaline liquids, they are speedily decomposed, becoming brown and black. Solutions of salts of silver, gold, platinum, and the allied metals are gradually reduced by gallic acid and its salts at the ordinary temperature.

Impurities and Adulterations.—Tannin is indicated in the aqueous solution of gallic acid by the white curdy precipitate produced on the addition of a solution of gelatin. Resinous substances would be insoluble in boiling water; sugar and dextrin would remain undissolved on treatment with spirit of ether; and mineral admixtures would remain behind upon heating the acid to redness.

Off. Prep.—Glycerinum (Glyceritum) acidi gallici, *U. S., Br.*

Derivative of Gallic Acid.—ACIDUM PYROGALLICUM, Pyrogallol, Pyrogallic Acid, $C_6H_6O_3 = C_6H_3(OH)_3$; mol. weight 126.—On heating gallic acid to sublimation, it is decomposed into carbonic acid and pyrogallol; $C_6H_6O_5$ yields $CO_2 + C_6H_6O_3$. A cheaper method is to heat in an apparatus suitable for preparing benzoic acid (see page 34) well-dried and powdered extract of nutgall, and, if necessary, to resublime the sublimate. Pyrogallic acid is in thin, white, pearly crystals of a bitter taste, fusing at 115° C. (239° F.), boiling at 210° C. (410° F.), and decomposed at 250° C. (482° F.). It is soluble in 2½ parts of water, and dissolves also in alcohol and ether. The aqueous solution acquires a red-brown color with ferric salts, and a dark-blue color with ferrous salts.

The solutions of salts of *pyrogallic acid*, like the moist acid itself, become reddish- and dark-brown on oxidation, and readily reduce the salts of mercury, silver, gold, and platinum. The acid is used in connection with silver nitrate in photography, and for hair-dyes and marking-inks. Stains produced by this acid on linen are best removed by washing with alcoholic solution of oxalic acid and exposure to the sun.

Medical Action and Uses.—Although gallic acid does not display any astringency in its taste or in its application to raw or bleeding surfaces, it certainly exerts a powerful control over all forms of passive hæmorrhage when taken internally, as well as

upon several of the secretions, and notably upon the urine and the sweat. Unlike tannic acid, it has no constipating effect upon the bowels. It is perhaps the first in value of the medicines used in *menorrhagia*. It should be given between the periods as well as during the flow, and in doses of from 10 to 20 grains a day, in pilular form. Of similar affections in which it is useful may be mentioned *purpura*, *epistaxis*, *hæmoptysis*, *hæmatemesis*, *hæmaturia*, and *intestinal hæmorrhage*. To the inordinate secretions which this acid tends to control belong *night-sweats* and other forms of profuse perspiration, and excessive secretion of urine in *polyuria* and in *Bright's disease*. Its influence in the last-named affection is often very prompt and salutary, since it not only reduces the total discharge of urine, but in a still larger proportion the loss of albumen. It is very efficient in correcting *pyrosis*, an annoying symptom of various dyspeptic conditions. Locally, it has been used in an ointment for the treatment of *alopecia*. The dose of gallic acid is from 5 to 20 grains (Gm. 0.30–1.20), repeated several times a day according to the urgency of the case. The glycerite is a convenient form for administering it.

Pyrogallic acid may act as an intense poison. Thus, in a case in which it was made into an ointment and rubbed freely into and bound upon the skin of a patient with psoriasis, it occasioned death in collapse, preceded by mucous vomiting and diarrhoea, rigors followed by fever, black and acid urine containing an abundance of globulin, and under the microscope the red corpuscles were found disorganized. Similar results were observed in experiments on animals by Neisser, who cautions those who may use the acid against corresponding dangers (*Zeitschrift f. klin. Med.*, i. 88). Besnier refers to four cases of psoriasis in which this acid produced toxic effects, and two ended fatally (*Med. News*, xlii. 128). In some experiments upon dogs and rabbits with this acid changes are said to have been found in the liver identical with those produced by phosphorus poisoning (E. Rousseau, *Inaug. Thesis*, Univ. of Penna., 1880).

Pyrogallic acid has been used with the best results, and without accident, in about 200 cases of *psoriasis* by Jarisch, and in a considerable number of these the application was made over a large portion of the body. It should not be applied too profusely to the diseased patches, and not at all to the sound skin (*Zeitschrift f. klin. Med.*, i. 631.). An ointment made with lard or with vaseline containing 10 per cent. of the acid was employed. But neither this nor any other topical application can effect a permanent cure of psoriasis, which is only the external and local manifestation of a systemic disease. It, however, stands hardly second to crysophanic acid as a remedy for psoriasis. It does not stain the hair or inflame the skin so much, although it colors the skin brown. It has the advantage, also, of being inodorous. Vidal used successfully in the treatment of phagedenic *syphilitic* ulcers an ointment made with 1 part of the acid to 5 of vaseline, and 1 part each of acid and of starch to 3 of vaseline. His results have been confirmed by Lermoyez and Hitier (*Bull. de thérap.*, c. 403). In *lupus* the ointment is said to attack the diseased nodules only, causing them to become necrosed and fall out, while the adjacent skin is not injured. In *epithelioma* the mode of action is the same in kind, but is slower and less complete (Jarisch, *Centralblatt f. Therapie*, i. 17).

ACIDUM HYDRIODICUM.—HYDRIODIC ACID.

Acidum iodhydricum.—*Acide iodhydrique*, Fr.; *Jodwasserstoffsäure*, G.

Formula HI. Molecular weight 127.6.

Origin.—Clement and Desormes (1813) recognized this acid, which was more fully investigated in the same year by Gay-Lussac. It is formed on the decomposition of metallic iodides by means of acids; on the ignition of a mixture of hydrogen and iodine vapors; and on the action of iodine upon various hydrogen compounds, or upon oxidizable bodies, like phosphorus and its lower oxides, arsenious acid, etc., in the presence of water.

Preparation.—As formerly official in the U. S. Pharmacopœia, it was prepared of such strength that 6 fluidounces contained the hydriodic acid from 480 grains of iodine. The process adopted was the one originally suggested by Gay-Lussac, modified by Le Royer and Dumas, according to which 30 grains of iodine are mixed with 5 fluidounces of water, and sulphuretted hydrogen is passed into the mixture until the color of iodine has disappeared. More iodine is now dissolved in the liquid, again sulphuretted hydrogen is passed into it until it is decolorized, and this process is repeated until all the iodine has been used. The liquid is then boiled until the odor of sulphuretted hydrogen is no longer perceived, filtered from the sulphur, and the filter washed with distilled water until the filtrate measures 6 fluidounces. It contains about 15 per cent. HI.

In the presence of water, iodine and sulphuretted hydrogen react with each other, the hydrogen uniting with the former, liberating sulphur; $2I_2 + 2H_2S$ yields $4HI + S_2$. The sulphur separates as a fine powder, which would cover the iodine and prevent the further reaction; to obviate this difficulty, a small quantity is first converted into hydriodic acid, which is a good solvent for iodine, and, with proper management, no iodine will be lost by remaining enveloped by the sulphur.

The process recommended by Buchanan (1837) consisted in dissolving 264 grains of tartaric acid and 330 grains of potassium iodide, each in $1\frac{1}{2}$ fluidounces of water, mixing and cooling the solutions, agitating for some time, straining from the precipitated bitartrate of potassium, and diluting with water to obtain $6\frac{1}{4}$ fluidounces. This acid speedily decomposes, for which reason J. Murdoch (1855) proposed to preserve it by sugar. It contains about 8 per cent. HI.

Properties.—Pure hydriodic acid is a colorless irrespirable and unflammable gas, having the density 4.37 and an odor resembling that of hydrochloric acid. The aqueous solution is colorless, has a strong acid reaction, and a pungent afterward styptic sour taste. The concentrated aqueous solution of the acid, saturated at 0° C. (32° F.), has the spec. grav. 1.99. The acid formerly officinal had the spec. grav. 1.112. The most concentrated acid obtainable by distillation boils at 127° C. (260.6° F.), contains 57.75 per cent. HI, and has the spec. grav. 1.708. Topsøe (1870) found an acid having at 13.5° C. (56.3° F.) the densities 1.077, 1.102 or 1.126 to contain respectively 10.15, 13.09, and 15.73 per cent. of HI. Exposed to the air, this acid is decomposed, the hydrogen being oxidized to form water, and iodine liberated, coloring the liquid red-brown. The addition of a small quantity of hyposulphite of sodium, as suggested by Dunn (1868), will for a time prevent the change. Pharmaceutically, hydriodic acid is a very unsatisfactory preparation.

Action and Uses.—According to Binz (*Arch. f. Pathol. u. Pharm.*, viii. 320), the poisonous phenomena produced by iodic acid proves that iodine is endowed with narcotic powers, and he quotes the assertion of Melsens, that hydriodic and iodic acids are equally operative. He and others also aver that the oxygen of the compound is its active element, and that the iodine is eliminated with the urine. The same authority maintains (*op. cit.*, xiii. 125), on the strength of his experiments, that iodic acid is an antipyretic, in that it reduces the pulse-rate; that its oxygen unites with and destroys “the decomposing products out of which the fever arises;” and that “the nascent iodine can only act upon the cells and ferment by reducing their activity.” It is unnecessary to pursue these ingenious but unpractical suggestions, which, however, induced Luton (*Traité des injections sous cutanées*, Paris, 1875) in 1873 to employ tissue injections of iodic acid in the treatment of certain degenerations. He held that the preparation was caustic in virtue of its iodine and resolute through its oxygen. He asserted it to be useful in certain ill-conditioned and especially canceroid ulcers, and that it might be injected into ganglions, goitres, and various other tumors; that its action was not more painful than that of iodine itself; and that, according to the strength of the solution, it acted as a caustic or simply resolved the morbid growths. For the former purpose a saturated solution was employed; for the latter, one containing a tenth of the acid or less. Internally, Wylie employed “a syrup containing 40 minims of the dilute (hydriodic) acid to the ounce,” of which 2 teaspoonfuls were given at a dose in chronic and subacute bronchitis, chronic malarial poisoning, and Graves’ disease (*Medical Record*, xv. 454). Binz (*loc. cit.*, p. 131) refers to experiments in which sick rabbits illustrated the antipyretic virtues of the preparation, and urges that its poisonous qualities do not constitute a sufficient objection to its use. Yet he prudently advises that the sodium salt, and not the acid, should be employed.

ACIDUM HYDROBROMICUM DILUTUM, U. S.—DILUTED HYDROBROMIC ACID.

Acidum bromohydricum.—*Acide hydrobromique*, Fr.; *Bromwasserstoffsäure*, *Hydrobromsäure*, G.

Formula HBr. Molecular weight 81 [80.8]. Strength 10 per cent. Sp. gr. 1.044.

Origin.—Hydrobromic acid was discovered by Balard (1826). It is formed by the direct union of its elements at a red heat, by the decomposition of sulphydric acid and other hydrogen compounds by bromine, by the action of bromine in the presence of water upon the lower oxides of sulphur, phosphorus, arsenic, and other elements,

and by the action of water upon the sulphur, phosphorus, and other compounds of bromine.

Preparation.—Markoe (1875) recommended the following procedure: 1 pound of phosphorus is spread over the bottom of a one-gallon jar, covered with water, and the jar half filled with ice, after which a large funnel is inserted into the throat of the jar, a funnel-tube adjusted so as to reach a short distance above the phosphorus, and the jar surrounded with ice. 3 or 4 pounds of bromine may now be very slowly added through the funnel-tube, care being taken to prevent the accumulation in the jar of uncombined bromine, which would give rise to an explosion when reacting with the phosphorus. The two elements unite to form pentabromide of phosphorus, PBr_5 ; and this, reacting with water, forms phosphoric and hydrobromic acids; $\text{PBr}_5 + 4\text{H}_2\text{O}$ yields $\text{H}_3\text{PO}_4 + 5\text{HBr}$. After the reaction is completed the excess of phosphorus is removed, and the aqueous liquid distilled until hydrobromic acid ceases to come over. The syrupy residue left in the retort, when properly diluted, is utilized as phosphoric acid.

Fothergill's formula is an adaptation of that of Dr. D. C. Wade (1875). An acid of the strength required by the Pharmacopœia, but containing small quantities of potassium bitartrate and bromide, may be prepared extemporaneously by dissolving 8 parts of potassium bromide and 10 parts of tartaric acid, each in 25 parts of distilled water, mixing the solutions, cooling the mixture, and stirring it well; after the potassium bitartrate has precipitated the whole is thrown upon a small funnel, and the vessel and precipitate are washed with 10 parts of ice-cold water.

The difficulties of distilling hydrobromic acid by decomposing potassium bromide with sulphuric acid have been overcome by Dr. Squibb (1878) as follows: 7 parts by weight of sulphuric acid, sp. gr. 1.838 at 15.6°C . (60°F .), are added to 1 part of water, and the mixture allowed to cool, when it is slowly, and with constant stirring, added to a hot solution of 6 parts of potassium bromide in 6 parts of water. A decomposition into hydrobromic acid and sulphate of potassium will take place; $2\text{KBr} + \text{H}_2\text{SO}_4$ yields $2\text{HBr} + \text{K}_2\text{SO}_4$. On setting the mixture aside for 24 hours, the salt crystallizes, the liquid is poured off into a retort, and the crystalline mass broken up, transferred to a funnel, and washed with 2 parts of cold water to recover adhering hydrobromic acid. The washings are likewise poured into the retort, which is placed upon a sand-bath or set upon a wire gauze, and the whole is then distilled nearly to dryness. The distillate, which weighs about 10 parts, is assayed with normal solution of soda, and then diluted with distilled water so as to contain 34 per cent. of HBr . When of this strength, the acid represents one-half the bromine strength of an equal weight of potassium bromide, and should be dispensed only as *acidum hydrobromicum concentratum*. According to W. Grüning (1883) distillation of the acid is readily accomplished by using 100 parts of potassium bromide and 250 parts of phosphoric acid, sp. gr. 1.304.

Ilager avoids distillation of the acid by operating as follows: 15.5 parts of potassium bromide are dissolved in 25 parts of hot water; the solution is mixed with 38 parts of sulphuric acid, spec. grav. 1.115, or 32 parts of water and 6.7 parts strong sulphuric acid, and the mixture cooled by immersing the flask in cold water; 40 parts of strong alcohol are added, and after 2 hours, when the potassium sulphate has separated, the liquid is filtered through glass-wool, and the vessel and filtrate washed with 15 or 20 parts of 60 per cent. alcohol; the clear filtrate is either evaporated or distilled at a temperature not exceeding 80°C . (176°F .) until the alcohol has been expelled. At the temperature named but very little hydrobromic acid is volatilized; the residue is diluted with water until it weighs 100 parts.

The process of Bruylants (1879) consists in carefully dropping bromine into oil of copaja, and afterward applying heat; the reaction is very energetic.

Properties.—Pure hydrobromic acid is a colorless gas of a pungent and irritating odor, and produces dense white fumes in a moist atmosphere. Its aqueous solutions are colorless, odorless, limpid liquids of a strongly acid taste, which remain colorless on exposure to air. Dr. Squibb determined the acid of the strength suggested by him to have the specific gravity 1.274 at 15.6°C . (60°F .), and to contain 33.58 bromine, .42 hydrogen, and 66 water. When heated, water and a weak acid distil over, and the temperature rises to 125.5°C . (258°F .), when an acid passes over which, according to Topsøe (1870), has at 14°C . (57.2°F .) the specific gravity 1.490 and contains 48.17 per cent. HBr .

Hydrobromic acid liberates bromine on the cautious addition of chlorine-water or of nitric acid, the bromine being soluble, with a yellow or orange-red color, in chloroform,

ether, and carbon bisulphide; and such a solution, agitated with starch paste, imparts to the latter a yellow color; excess of chlorine-water will destroy the color.

The density of aqueous hydrobromic acid at 15° C. (59° F.), according to Biel (1881), is as follows:

Per ct. HBr.	Spec. grav.	Per ct. HBr.	Spec. grav.	Per ct. HBr.	Spec. grav.	Per ct. HBr.	Spec. grav.	Per ct. HBr.	Spec. grav.
1	1.0082	11	1.085	21	1.172	31	1.270	41	1.388
2	1.0155	12	1.093	22	1.181	32	1.281	42	1.401
3	1.0230	13	1.102	23	1.190	33	1.292	43	1.415
4	1.0305	14	1.110	24	1.200	34	1.303	44	1.429
5	1.038	15	1.119	25	1.209	35	1.314	45	1.444
6	1.046	16	1.127	26	1.219	36	1.326	46	1.459
7	1.053	17	1.136	27	1.229	37	1.338	47	1.474
8	1.061	18	1.145	28	1.239	38	1.350	48	1.490
9	1.069	19	1.154	29	1.249	39	1.362	49	1.496
10	1.077	20	1.163	30	1.260	40	1.375	50	1.513

Tests.—Hydrobromic acid should evaporate without leaving any residue. It should not be precipitated by barium chloride, showing the absence of sulphuric acid. It yields, like hydrochloric acid, white precipitates with solutions of lead, mercurous and silver salts. Bromide of silver is nearly insoluble in *dilute* ammonia-water, which dissolves silver chloride readily; on the subsequent addition of nitric acid only a slight turbidity should be produced. If contaminated with hydriodic acid, the latter on exposure to air will liberate iodine, which gives a blue color with starch. On cautiously adding chlorine-water to such an acid, iodine will first be liberated, and dissolve in carbon bisulphide with a purple color; on the further addition of the reagent bromine will be liberated. The strength of hydrobromic acid may be determined by neutralization or by silver. 16.2 Gm. of the official acid require for neutralization 26 Ccm. of the volumetric solution of soda; and 10 Gm. of it, when treated with nitrate of silver in excess, will yield a precipitate which, after washing and drying, weighs 2.32 Gm., and when heated in chlorine gas is converted into chloride of silver weighing 1.72 Gm.

Physiological Action.—In its liquid and diluted state, and particularly when prepared by decomposing bromide of potassium with tartaric acid, it has an agreeable acidulous taste; but the pure acid is as corrosive as concentrated hydrochloric acid. The experiments of Reichert (1881) appear to prove conclusively that the action of hydrobromic acid is essentially the same as that of potassium bromide. Its operation is, however, more transient. It is of interest to note that, like other agents classed as narcotic, it is stimulant in small doses, and in large doses depressing. It is less apt than its potassium salt to provoke an acneiform eruption.

Medical Uses.—It was first employed to prevent the headache occasioned by quinine, and also by iron, by combining it with those medicines, as well as to palliate the nervous irritability or disorders for which they are often prescribed. It soon appeared to be, in many cases, an appropriate substitute for bromide of potassium, and at least equal that salt in the energy, if not in the duration, of its action upon the nervous system. In combination with quinine and iron, its own comparatively transient influence forms an appropriate preparation for their more permanent action. It especially seems to prevent the *timitus aurium* and the disorder of vision which sometimes follow the use of large doses of quinine. But as these phenomena are often the only guides in regulating the dose of quinia, a medicine capable of suppressing them is of questionable advantage unless the appropriate dose of quinine has been experimentally determined. It appears to co-operate with digitalis as well as with quinine and iron in improving the tone of the heart when weak and irritable. Like the bromides, it has been successfully employed in a variety of nervous disorders induced by reflex irritation, such as *vomiting*, *muscular spasm*, *whooping cough*, and *neuralgia*, and in *coughs* excited by *bronchial* or *laryngeal* irritation. In cases also of *cerebral hyperæmia* due to excessive mental activity in study, business, etc. it appears to have the same influence as the bromides. In *timitus aurium* and other subjective sensations in the ear, especially those of a throbbing or knocking character, depending upon vascular congestion, the medicine has proved very efficient. Unlike the bromides, it appears to be more injurious than useful in *epilepsy*, aggravating the attacks and rendering them more frequent. Such, at least, is the result of some clinical observation. But it is to be remembered that doses of the acid corresponding to full doses of the bromide must be very large indeed, and hence inconvenient. It has been sug-

gested that the acid may be substituted wholly or partly for the salt to check the development of the bromide eruption and of the debilitating influence of its alkaline base. Dr. Squibb has called attention to the difficulty of administering the acid "in consequence of the large dilution necessary and the disagreeable effect of" setting the teeth on edge. "A dose of 50 grains requires not less than 8 fluidounces of dilution, which must contain not less than an ounce of sugar or 2 ounces of syrup to make it drinkable." Doses of about half this amount have been found necessary to produce a prompt sedative effect. Dr. Squibb has proposed the use of a syrup containing about 3 minims of his acid in each fluidrachm. Half an ounce of this syrup contains about 15 grains of the acid, and is reckoned to be equivalent to 12.5 grains of potassium bromide. It must be given diluted with from 2 to 4 ounces of water. Hydrobromate of quinine, being very soluble in water, is more suitable than the neutral sulphate for hypodermic use. It may be prepared thus: $\mathcal{R}$. Potassii bromid. 162 gr.; Acid. tartaric. 198 gr.; Quininæ sulph. 60 gr.; Aquæ f 3ijj. —M. Filter. Dose, 30 minims to 1 fluidrachm (Gm. 2-4).

ACIDUM HYDROCHLORICUM, U. S., Br., P. G.—HYDROCHLORIC ACID.

Acidum muriaticum, s. *hydrochloratum* s. *chlorhydricum*.—*Muriatic acid*, E.; *Acide chlorhydrique* s. *muriatique*, Fr.; *Salzsäure*, *Chlorwasserstoffsäure*, G.

Formula HCl. Molecular weight 36.4. Strength 31.9 per cent. (25 per cent. P. G.). Spec. grav. 1.160.

Diluted Hydrochloric Acid: Strength 10 per cent. U. S., 10.58 per cent. Br., 12.5 per cent. P. G. Spec. grav. 1.049 U. S., 1.052 Br., 1.061 P. G.

Origin.—Hydrochloric acid occurs in the uncombined state among the gases emitted by active volcanoes, and in combination its radical, chlorine, is found in numerous minerals, prominent among which is chloride of sodium, or common salt, which is also one of the most important constituents of sea-water and the source of nearly all the hydrochloric acid of commerce. The acid was obtained in the fifteenth century by Basilius Valentinus, and was described as *spirit of salt*, a name which is occasionally used even at the present time. The correct composition of hydrochloric acid was first proved by Humphry Davy (1810).

Preparation.—Enormous quantities of hydrochloric acid are produced in the preparation of potash and of carbonate of sodium, for which purpose it is necessary to convert the chlorides into sulphates. The escaping gas is made to pass through long vertical cylinders, which are filled with coke, over which water is made to trickle. The water, dissolving the acid in its descent, is collected below or allowed to run to waste. If the acid is intended for uses in the arts, a purer article is required, and the gas is then made to pass through a series of stone receivers having the shape of large Woulfe's bottles, the first of which is empty, while the other five or six contain a certain quantity of water. The stills consist of horizontal iron cylinders, into which equal weights of common salt and sulphuric acid are introduced, after which heat is applied. The first receiver retains any sodium sulphate and sulphuric acid which may be mechanically carried over, the gas being absorbed by the water in the other receivers.

By this process 117 parts of chloride of sodium require 98 parts of concentrated (or a correspondingly larger quantity of a somewhat weaker) sulphuric acid. The first reaction results in liberation of one-half of the hydrochloric acid and production of acid sulphate of sodium; $2\text{NaCl} + \text{H}_2\text{SO}_4$ yields $\text{HCl} + \text{NaCl} + \text{NaHSO}_4$. The decomposition of the remaining chloride by the acid sulphate of sodium is effected at a temperature beyond 200°C . (392°F .), but on the large scale a much higher heat is found necessary; the reaction takes place as follows: $\text{NaCl} + \text{NaHSO}_4 = \text{HCl} + \text{Na}_2\text{SO}_4$. The salt cake remaining in the retort is worked up into Glauber's salt by dissolving it in water and crystallizing, or it is used for the preparation of soda. The acid thus obtained has a lighter or deeper yellow color, due to a small quantity of ferric chloride dissolved in it. If otherwise pure and of sufficient strength, it may be employed for preparing ferrous and ferric chlorides.

In a process recommended by Eschellmann (1882) the product obtained in preparing hydrochloric acid may be again utilized for the same purpose: calcium chloride and magnesium sulphate are mixed with water to form a soft mass, and then heated to dull redness. The reaction taking place is explained by the equation $\text{CaCl}_2 + \text{MgSO}_4 + \text{H}_2\text{O} = (\text{MgO} \cdot \text{CaSO}_4) + 2\text{HCl}$. The basic calcium-magnesium sulphate may be used for generating ammonia from sal ammoniac, resulting in the formation of calcium sulphate and magnesium chloride, from which the above basic sulphate and hydrochloric acid gas

may be again obtained. On treating in the same manner a mixture of chloride and sulphate of magnesium, the result is, besides hydrochloric acid, basic magnesium sulphate, MgO.MgSO_4 , from which, on boiling with water, magnesium hydrate is precipitated, while magnesium sulphate remains in solution.

A pure acid, suitable for pharmaceutical purposes, is obtained by rectifying 12 parts of the crude acid in a glass retort in such a manner that the delivery-tube terminates at the surface of 3 parts of distilled water contained in the receiver, which is refrigerated with water; the heat is continued until about 7 parts have distilled over. The pure acid is usually prepared on a large scale by distilling chloride of sodium and sulphuric acid in the proportions given above, using glass retorts having a capacity of 5 or 6 gallons, and collecting the acid in suitable glass receivers; a number of these retorts are usually arranged in a properly constructed furnace having the requisite number of sand-baths, each of which is large enough to receive one retort, and may be sufficiently heated to recover all hydrochloric acid, with the production of sodium sulphate. In the pharmaceutical laboratory, however, it is usually preferable to employ the sulphuric acid in such a quantity that acid sulphate of sodium is formed, since the hydrochloric acid is then obtained at a lower temperature; $\text{NaCl} + \text{H}_2\text{SO}_4 = \text{HCl} + \text{NaHSO}_4$. For 3 parts of dry chloride of sodium but little more than 5 parts of concentrated sulphuric acid are required, and these are the proportions employed in the following process, which likewise contains the necessary details for successfully carrying on the operation:

Take of Chloride of Sodium, dried, 48 ounces; Sulphuric Acid 44 fluidounces (80 ounces); Water 36 fluidounces; Distilled Water 50 fluidounces. Pour the sulphuric acid slowly into 32 ounces of the water, and when the mixture is cooled add it to the chloride of sodium previously introduced into a flask having the capacity of at least 1 gallon. Connect the flask by corks and a bent glass tube with a three-necked wash-bottle furnished with a safety-tube and containing the remaining 4 ounces of the water; then, applying heat to the flask, conduct the disengaged gas through the wash-bottle into a second bottle containing the distilled water by a bent tube, dipping about half an inch below the surface, and let the process be continued until the product measures 66 ounces or the liquid has acquired a specific gravity of 1.16. The bottle containing the distilled water must be kept cool during the whole operation.—*Br.*

ACIDUM HYDROCHLORICUM (S. MURIATICUM) DILUTUM, U. S., *Br.*—*Diluted hydrochloric acid*, E.; *Acide chlorhydrique diluée*, Fr.; *Verdünnte Salzsäure*, G.—Add Hydrochloric Acid 6 parts to Distilled Water 13 parts, and mix.—*U. S.* The British Pharmacopœia adds to 3060 grains of hydrochloric acid sufficient distilled water, until the mixture, at 15.5°C . (60°F .), after it has been shaken, measures 1 imperial pint. The specific gravity of diluted hydrochloric acid is 1.049 *U. S.*, 1.052 *Br.*, 1.061 *P. G.*

Properties.—1. HYDROCHLORIC ACID GAS. It is colorless, has a pungent, acid, suffocating odor, and when inhaled is highly irritating, though less so than chlorine. Its specific gravity is 1.2844 (Thomson). It strongly reddens blue litmus-paper, does not support combustion, and in contact with the atmosphere produces grayish-white fumes by condensing the moisture of the air. It may be condensed into a colorless liquid by a pressure of 1 atmosphere and a refrigerating mixture of solid carbonic acid and ether. This liquid does not congeal at 110°C . (166°F .), and at 10°C . (50°F .) exerts a pressure equal to 40 atmospheres. Its composition is HCl , or equal volumes of hydrogen and chlorine united without condensation.

2. CRUDE HYDROCHLORIC ACID, *Acidum hydrochloricum crudum*, *P. G.*; *Spiritus salis*.—The German Pharmacopœia requires it to have a specific gravity of not less than 1.158, and to contain at least 29 per cent. of HCl . It is of a yellowish color, and usually contains traces of sulphuric and sulphurous acids, aluminium, and iron. It should, however, be free from arsenic, which may be detected, according to Bettendorff (1869), by adding 1 Gm. of stannous chloride to 10 Gm. of the acid, and either heating or setting aside for half an hour, when a brown turbidity or precipitate will occur, consisting of metallic arsenic. One-millionth part of arsenic may thus be detected, provided the acid has not been diluted. After the precipitate has settled the clear liquid may be carefully decanted or filtered, and afterward distilled, when it will be free from arsenic and tin.

3. OFFICIAL HYDROCHLORIC ACID.—It is a colorless liquid, having the specific gravity 1.160, and emitting white vapors in contact with the air. It gives with nitrate of silver a white curdy precipitate, which is soluble in ammonia and insoluble in nitric acid. The strength of the acid is determined, after suitably diluting it with distilled water by neutralizing it with volumetric solution of soda. 3.64 Gm. of the former require 31.9 Cem. of the latter (*U. S.*); or 114.8 grains of acid need 1000 grain-measures of the soda solution

(Br.). Pure hydrochloric acid of the German Pharmacopœia is required to have the density 1.124, and to contain 25 per cent. HCl.

Water absorbs at 0° C. (32° F.), the barometer being 760 Mm., 501.5 volumes of hydrochloric acid gas. The concentrated acid, on being heated, loses gas, becoming weaker on boiling until, at the barometric pressure given before, it has reached the specific gravity 1.101 at 15° C. (59° F.), contains 20.17 per cent. HCl, and distils at 110° C. (230° F.). On boiling a weaker acid it becomes stronger, the final density depending on the atmospheric pressure.

Hydrochloric acid of the specific gravity 1.01 at 25° C. (77° F.) contains, according to E. Davy, 2.02 per cent. of gas, and for every additional 2.02 per cent. increases in density at the ratio of 0.01, so that an acid of 1.10 specific gravity contains 20.20 per cent., and if of specific gravity 1.19 contains 38.38 per cent. of gas. These figures differ little from those ascertained by A. Ure, from whose results the following table is condensed, giving

Sp. grav.	Per cent. chlorine.	Per cent. HCl.	Per cent. aqueous acid.		Sp. grav.	Per cent. chlorine.	Per cent. HCl.	Per cent. aqueous acid.

the percentage of chlorine, of hydrochloric acid gas, and of the aqueous acid of specific gravity 1.200 contained in hydrochloric acid of different densities; we have also added the figures ascertained by J. Kolb (1872) for 15° C., giving the percentage of dry HCl and of the acid of 20° Baumé.

DILUTED HYDROCHLORIC ACID has the same properties as the strong acid, but contains only 10 per cent. (*U. S.*), 10.58 per cent. (*Br.*), 12.5 per cent. (*P. G.*) of HCl, and has the specific gravity of 1.049 (*U. S.*), 1.052 (*Br.*), 1.061 (*P. G.*). The amount of volumetric solution of soda required for neutralization is 10 Ccm. for 3.64 Gm. of the acid (*U. S.*), or 1000 grain-measures for 345 grains of the latter (*Br.*).

Impurities and Tests.—Hydrochloric acid evaporates completely without leaving any residue (saline impurities). When diluted with at least four times its volume of distilled water it yields no precipitate with sulphuretted hydrogen (lead, copper, arsenic, tin), chloride of barium (sulphuric acid), or ammonia in excess (lead, iron); nor does it acquire a blue color with the last test (copper), or a brown or black color on the subsequent addition of sulphhydrate of ammonium (metals); it is not colored red by sulphocyanide of potassium (iron), or blue by a mixture of starch-paste and iodide of potassium (chlorine), and does not tarnish or alter the color of bright copper-foil when boiled with it (arsenic). To test it for sulphurous acid or arsenic, put a few pieces of pure zinc into a rather long test-tube and introduce the hydrochloric acid, diluted with 2 parts of water, which should fill about one-tenth part of the tube. In the upper part of the tube place a small bunch of cotton moistened with solution of acetate of lead, and cover the mouth of the tube with a piece of white filtering-paper moistened with solution of nitrate of silver. After the evolution of hydrogen gas has continued for half an hour neither the cotton nor the paper should be blackened, proving the absence of sulphurous acid in the former case and of arsenic in the latter. Under the conditions described sulphurous acid evolves sulphuretted hydrogen, which blackens the lead salt, and arsenic yields arseniuretted hydrogen, which does not affect lead acetate, but blackens nitrate of silver.

Pharmaceutical Uses.—Hydrochloric acid is employed in numerous processes, either on account of its properties as a solvent for decomposing certain compounds with the view of liberating certain constituents (sulphur, carbonic acid, hydrocyanic acid, etc.), or for the purpose of generating chlorine. It is used in the preparation of nitromuriatic acid and of the various officinal chlorides, and for promoting the precipitation of resin of podophyllum.

Physiological Action.—Injected into the veins of an animal, it coagulates the blood, but not so firmly as sulphuric acid. Given to man in small doses, it occasions a sense of warmth in the stomach and arterial excitement, with a decided tendency to cerebral intoxication. Its protracted use causes salivation. In a concentrated form it attacks the tissues as a caustic, but less powerfully than nitric or sulphuric acid. An ounce of the officinal acid has been taken without causing death. The symptoms of poisoning by hydrochloric acid are sunken features, dilated pupils, a white stain upon the tongue and fauces, a small, irregular, and feeble pulse, epigastric pain, and cold extremities. Vomiting and purging sometimes occur. After large doses, as 3 or 4 ounces, death takes place in from 3 to 6 hours. After death the pharynx is shrivelled and white, the œsophagus blackish-gray, the vessels are filled with coagulated blood, the gastric mucous membrane is dark and thinned, the walls of the stomach are sometimes perforated, and in that case there is peritonitis. In some instances fatty infiltration has been found. (For recent cases (1883) compare *Virchow's Archiv*, lxxiii. 214; *Edinburgh Med. Jour.*, xxvi. 1093; *Med. Times and Gaz.*, Apr. 1883, pp. 471, 609.)

Medical Uses.—Hydrochloric acid was at one time extensively employed in *low fevers*, probably upon theoretical grounds which have disappeared along with the practice. It was vaunted in *dyspepsia*, *scrofula*, and other affections involving debility; but, as it was associated with cinchona, its share in whatever benefit accrued is more than doubtful. Perhaps upon better grounds it may be recommended for constitutional *syphilis* when mercury and iodine are inappropriate. But, not improbably, its use in this disease may be attributed to its sometimes causing salivation. It has been employed in *calculus* complaints, and perhaps advantageously in so far as they were associated with dyspeptic disorders. In this way, possibly, it may be found useful in eczema and psoriasis and other *diseases of the skin*, which sometimes depend upon digestive derangements. Hydrochloric acid was at one time regarded as a most valuable agent in the treatment of *diphtheria*, but recent experience has shown that the local affection is of subordinate importance, and that the mere removal of the exudation does not modify the disease. Moreover, chlorate of potassium and other agents are more eligible than the acid as pal-

liatives of the pharyngeal inflammation. The same may be said, even more emphatically, of gangrenous, mercurial, scorbutic, and other forms of ulcerative *stomatitis*. According to Vololini, *fish-bones* lodged in the pharynx are rendered flexible and may finally be broken up by a mixture of 4 parts of hydrochloric acid and 240 parts of water, the teeth being first protected by oil or lard. The method is probably not to be relied on. A poisonous dose of this acid should be counteracted by magnesia, soap, bicarbonate of sodium, or, in the absence of these, by albumen. The dose of the stronger acid is from 5 to 30 minims (Gm. 0.30–2.00); of the weaker acid, from 20 to 60 minims (Gm. 1.30–4.00), largely diluted and taken through a glass tube. As a gargle, 1 or 2 fluidrachms of the stronger acid may be diluted with 10 or 12 ounces (Gm. 4–8 in Gm. 350–400) of barley-water sweetened with honey.

ACIDUM HYDROCYANICUM DILUTUM, U. S., Br.—DILUTED HYDROCYANIC ACID.

Acidum hydrocyanatum s. borussicum.—Prussic acid, E.; *Acide cyanhydrique s. hydrocyanique*, Fr.; *Cyanwasserstoffsäure, Blausäure*, G.

Formula $\text{HCN} = \text{HCy}$. Molecular weight 27. Strength 2 per cent. HCy .

Origin.—Hydrocyanic acid was discovered by Scheele (1782); Berthollet (1803) ascertained it to be a compound of hydrogen, carbon, and nitrogen; and Gay-Lussac (1815) succeeded in analyzing it and in isolating the radical *cyanogen*, CN . The acid has been found in the root of *Janipha Manihot*, and in the bark, leaves, flowers, and seeds of many shrubs and trees belonging to the sub-orders *Amygdaleæ* and *Pomeæ* of the order *Rosaceæ*. It occurs in the free state only in some of the more juicy parts of these plants, but a larger quantity is formed on macerating the parts indicated in cold water, when the amygdalin contained therein is split by the action of emulsin or a similar ferment into sugar, oil of bitter almonds, and hydrocyanic acid: $\text{C}_{20}\text{H}_{27}\text{NO}_{11}$ (amygdalin) + $2\text{H}_2\text{O}$ yields $2\text{C}_6\text{H}_{12}\text{O}_6$ (glucose) : $\text{C}_7\text{H}_6\text{O}$ (oil of bitter almonds) : HCN (hydrocyanic acid). It is likewise found among the products of the reaction of nitric and nitrous acids upon many organic compounds, and of gaseous ammonia upon incandescant charcoal. For medicinal purposes it is mostly prepared by the decomposition of ferrocyanide of potassium by means of sulphuric acid.

Preparation.—Place 20 parts of ferrocyanide of potassium in a tubulated retort, and add to it 40 parts of water. Connect the neck of the retort (which is to be directed upward), by means of a bent tube, with a well-cooled condenser, the delivery-tube of which terminates in a receiver surrounded with ice-cold water and containing 60 parts of diluted alcohol. All the joints of the apparatus, except the neck of the receiver, having been made air-tight, pour into the retort, through the tubulure, 15 parts of sulphuric acid previously diluted with an equal weight of water. Agitate the retort gently, and then heat it in a sand-bath until the contents are in brisk ebullition, and continue the heat regularly until there is but little liquid mixed with the saline mass remaining in the retort. Detach the receiver, and add to its contents so much distilled water as may be required to bring the product to the strength of 2 per cent. of absolute hydrocyanic acid.—U. S.

The process of the British Pharmacopœia is similar to the foregoing, differing chiefly in distilling from a weaker solution and in collecting the distillate in distilled water. The proportions employed are 2½ ounces of potassium ferrocyanide dissolved in 10 ounces of water, and 1 fluidounce of sulphuric acid diluted with 4 ounces of water; the receiver contains 8 ounces of distilled water, and the distillation is continued until the liquid is increased to 17 fluidounces, when it is diluted with distilled water so as to contain 2 per cent. of hydrocyanic acid.

On mixing diluted sulphuric acid with the solution of ferrocyanide of potassium in the cold, only one-half of the latter salt is decomposed, with the formation of sulphate of potassium and hydro-ferrocyanic acid, thus: $\text{K}_4\text{FeC}_6\text{N}_6$ (ferrocyanide of potassium) + $2\text{H}_2\text{SO}_4$ yields $2\text{K}_2\text{SO}_4 + \text{H}_4\text{FeC}_6\text{N}_6$ (hydro-ferrocyanic acid). This last compound may be obtained by adding ether to the mixture, when the acid will be separated as a whitish powder or pearly scales. On the application of heat to the mixture this acid reacts with the remaining ferrocyanide of potassium and sulphuric acid, yielding hydrocyanic acid, which distils over, sulphate of potassium, which remains in solution, and ferrocyanide of iron and potassium (Everitt's salt), which precipitates as a white powder, rapidly turning green, and finally blue, in the presence of oxygen. The reaction is explained in the following: $\text{H}_4\text{FeC}_6\text{N}_6 + \text{K}_4\text{FeC}_6\text{N}_6 + \text{H}_2\text{SO}_4 = 6\text{HCN}$ (hydrocyanic acid)

+ $K_2SO_4 + K_3Fe(FeC_6N_6)$ (Everitt's salt). 2 molecules of ferrocyanide of potassium with 3 of sulphuric acid yield, therefore, finally, 6 molecules of hydrocyanic acid, 3 of potassium sulphate, and 1 of Everitt's salt, the latter having a white color, but turning rapidly blue on exposure.

The preparation of official hydrocyanic acid by the above process presents no difficulties. Distilling the acid over a naked fire would cause concussions endangering the safety of the retort. The Pharmacopœia very properly orders the retort to be placed in a sand-bath, or an ash-bath may be substituted for it. The complete decomposition of the potassium ferrocyanide and the distillation of the hydrocyanic acid are readily effected, the entire amount being obtainable at a temperature little exceeding that of boiling water. The contamination of the distillate with the contents of the retort, which may occur in consequence of spirting, is easily prevented by substituting a flask for the retort or by keeping the neck of the latter in a slightly elevated position.

The strength of the distillate may be determined by weighing 100 grains of it in a small beaker containing some distilled water, and precipitating completely with nitrate of silver; the precipitate of cyanide of silver is collected upon a tared filter, washed, dried at $100^{\circ} C.$ ($212^{\circ} F.$), and weighed. From the excess of this weight over 10 grains the amount of distilled water is easily calculated, which must be added to the distillate, the precise weight of which has been ascertained, in order to obtain it of the official strength. After proper dilution it should at once be put into clean small vials, well corked.

The amount of hydrocyanic acid contained in the distillate may also be determined volumetrically by diluting 6.75 Gm. of it with twice its bulk of water, adding to this volumetric solution of nitrate of silver as long as a white turbidity of $AgCy$ is produced. Since, however, the termination of the reaction is not readily observed, the Pharmacopœia directs the addition to the acid of a few drops of potassium chromate as an indicator in producing a permanent red precipitate as soon as all the hydrocyanic acid has been converted into silver cyanide. If of the proper pharmacopœial strength the above quantity of HCy will require exactly 50 Ccm. of the silver solution: any excess of the latter which may be required will indicate by a simple proportion the amount of distilled water which must be added to the distillate.

Liebig's method depends upon the formation of a soluble double salt, $KCy.AgCy$, which is not decomposed by potassa or sodium chloride. As before, 6.75 Gm. of the distillate may be conveniently used; this is rendered slightly but distinctly alkaline by potassa, after which the silver solution is added until a permanent white turbidity appears. An acid containing 2 per cent. HCy will require 25 Ccm. of the test solution, and the excess above this quantity will furnish the proportion for diluting the distillate to its proper strength.

Diluted hydrocyanic acid may be advantageously prepared from several cyanides. Cyanide of potassium, however, is not well adapted for this purpose, owing to the difficulty of obtaining it absolutely pure; but even if the salt were decomposed by the requisite quantity of tartaric acid to form bitartrate of potassium, the portion of the latter salt remaining in solution would tend to speedily decompose the acid, unless distillation were resorted to. A convenient method for obtaining an acid suitable for immediate use is the following:

Take of Cyanide of Silver 6 parts (50 grains); Hydrochloric Acid 5 parts (42 grains); Distilled Water 55 parts (1 fluidounce). Mix the hydrochloric acid with the distilled water, add the cyanide of silver, and shake the whole together in a glass-stoppered vial. When the precipitate formed has subsided pour off the clear liquid.—*U. S.*

The hydrochloric acid decomposes the silver cyanide, forming insoluble silver chloride and hydrocyanic acid; thus, $AgCy + HCl = AgCl + HCy$.

The French Codex employs a mixture of cyanide of mercury and chloride of ammonium, the latter being used to produce readily soluble and fusible double salts. The mixture is treated with hydrochloric acid, and the resulting gas passed first over marble to remove hydrochloric acid, and then over chloride of calcium to remove water, into a narrow tube placed in a refrigerating mixture. The anhydrous acid is condensed, and is diluted with nine times its weight of distilled water. This process presents no advantages whatever. On the contrary, owing to the concentration of the acid as at first condensed, precautions are necessary to avoid dangerous results in handling this volatile liquid.

Properties.—Anhydrous hydrocyanic acid is a colorless mobile liquid which congeals at $-15^{\circ} C.$ ($5^{\circ} F.$) to feathery crystals, has the density .697 at $18^{\circ} C.$ ($64.4^{\circ} F.$), boils at $26.5^{\circ} C.$ ($79.7^{\circ} F.$), and when ignited burns with a slightly luminous flame to carbonic anhydride and nitrogen. It has a strong odor, resembling that of oil of bitter

almond, and is extremely poisonous. It is the hydride of the radical cyanogen, and its composition is expressed by the formula $\text{HCN} = \text{HCy}$. It reddens litmus-paper slightly and transiently, and with alkalis yields crystallizable salts having a strong alkaline reaction, and producing with an acidulated mixture of ferrous and ferric salts a precipitate of Prussian blue. Most of its salts, on being treated with diluted mineral or many organic acids, yield hydrocyanic acid, and are decomposed by strong nitric acid, with the evolution of nitrogen and other gases; cyanide of silver dissolves in boiling nitric acid, the solution containing silver nitrate. A solution of an alkaline cyanide mixed with solution of picric acid and heated to about 60°C . (140°F .) acquires a deep-red color, from the production of a salt of *isapurpuric* or *pirocyanic acid*, $\text{C}_6\text{H}_5\text{N}_5\text{O}_6$ (Hlasiwetz, 1859).

Hydrocyanic acid is soluble in water, alcohol, and ether in all proportions. The medicinal acid contains 2 per cent. of anhydrous acid; the aqueous solution of this strength has the spec. grav. 0.997 (*Br.*). The methods for ascertaining the strength have been given above. Minute quantities of hydrocyanic acid may be detected by Schenbein's (see *GRACIUM*) or by Liebig's test (1847); the latter is applied by adding a little sulphhydrate of ammonium, evaporating at a moderate heat to dryness, and adding to the residue a drop of diluted ferric chloride, when the blood-red color of ferric sulphocyanide will appear.

Under various circumstances hydrocyanic acid is decomposed on keeping, evolving ammonia and depositing a brown or blackish substance containing paracyanogen, C_3N_3 or C_6N_6 . The causes of these changes have not been fully explained; it is, however, well known that the presence of alkalis and exposure to the light favor decomposition; and since, by heating hydrocyanic acid in the presence of free mineral acids, formiate of ammonium is apt to be produced, it will be seen that even recently prepared dilute hydrocyanic acid may be prone to change, and that, if altered, the decomposition cannot be arrested by distillation except after the previous addition of sufficient sulphuric acid. The addition of a minute quantity of hydrochloric acid, and of alcohol in place of a portion of the water, to the recently prepared acid, appears to retard that change, but does not altogether prevent it. The stronger the hydrocyanic acid is, the more liable it is to decomposition. The acid known as Scheele's acid, which contains 5 per cent. of HCy , is therefore not adapted for medicinal use.

Another difficulty in preserving the strength of hydrocyanic acid must be attributed to its volatility and the loss suffered by the medicinal acid on the frequent opening of the vial containing it. This has recently (1873 and 1874) been the subject of investigation by A. Towerzey and others. J. Williams states that an addition of 20 per cent. of glycerin will preserve acid up to the strength of about 5 per cent., and J. U. Lloyd (1878) observed that alcoholic hydrocyanic acid could be kept in partially-filled bottles unaltered and without material loss of acid for three years. The formula of the U. S. Pharmacopœia has been modified in accordance with this observation; but it appears better by far to abandon the present medicinal hydrocyanic acid altogether, as suggested by G. A. Zwick, and to adopt in its place, like the Prussian Pharmacopœia of 1862, a still more diluted acid, containing $\frac{1}{10}$ per cent. of HCy , which has been admitted into the German Pharmacopœia (1872 and 1882) under the name of *Aqua amygdalarum amararum*. This will preserve its strength even in partly-filled bottles for several months.

Impurities.—On adding a few drops of solution of corrosive sublimate, and heating to boiling, a reduction of the mercuric salt to calomel or to mercury will indicate the presence of formic acid. Sulphuric acid is recognized by the white precipitate produced on the addition of chloride of barium. Hydrochloric and phosphoric acids are detected by adding solution of borax, evaporating to dryness, and dissolving the residue in diluted nitric acid; a white precipitate with nitrate of silver will indicate the former, and a yellow precipitate with molybdate of ammonium the latter impurity.

Off. Prep.—Vapor acidi hydrocyanici, *Br.*

Derivative.—HYDROCYANIC ETHER, *ethylcyanide* or *propionitrile*, $\text{C}_3\text{H}_5\text{N} = \text{C}_2\text{H}_5\text{CN}$. Prepared according to Pelouze's process (1834), by distilling sulphovinate of barium with potassium cyanide, it has a garlicky odor, which is due to the isomeric *ethylcarbylamin*, and is difficult to remove. A purer product is obtained, according to Williamson (1853), by digesting iodide of ethyl with 4 parts of alcohol containing an equivalent quantity of potassium cyanide until decomposed, and then distilling. When perfectly pure, it is a colorless liquid of the density 0.787, has an agreeable ethereal odor, suggesting that of hydrocyanic acid, is almost insoluble in water, and boils at 97°C . (206.6°F). It is poisonous, but less so than hydrocyanic acid.

Physiological Action.—This acid is hostile to all forms of life. However absorbed into the tissues of vegetables, it arrests their functions more or less completely. Under its influence woody stems shrink and grow dry, and succulent plants exude their moisture through the integument. All animals are affected by it, but birds and mammals more than reptiles and fishes. Of all poisons, it produces its effects most rapidly—sometimes too rapidly to be analyzed or even accurately observed. The following summary represents them in their usual order: 1. Difficult breathing, slow and full pulse, giddiness, and loss of muscular power. 2. Spasms, dilated pupils, loss of consciousness, vomiting, muscular rigidity, with cessation of the pulse and heart's action. 3. Muscular relaxation and collapse, with abolished or impaired sensibility, feeble pulse, and death by asthenia or in convulsions induced by peripheral irritation. If the dose is not fatal, the animal passes from complete resolution to exaggerated reflex irritability and apparent sensibility; this condition is usually followed by deep sleep. After death the eyes have a glassy lustre, the pupils are usually dilated, and cadaveric rigidity is very marked. If death has been gradual, the blood is found dark and uncoagulated, distending both sides of the heart; but if the poison has been rapidly fatal, the left side of the heart is empty and contracted, but the right is filled with blood. In rapid death from this poison the blood of both systems may exhibit the arterial hue. The cause of this phenomenon is undetermined. The extreme rapidity of the action of the poison and the nature of its effects, as well as the results of special experiments, render it probable that they are due to its direct influence upon the heart itself, and not upon the blood alone, nor upon that and the cerebro-spinal centres primarily. The nervous symptoms appear to be secondary, and due to the withdrawal of blood from the nervous centres. Experiments upon the horse and the hyena show that those animals are nearly insusceptible to the influence of the poison; the elephant, on the other hand, is destroyed by a relatively small dose of it.

In man, the acid, when taken in medicinal but still over-active doses, may produce the following symptoms: irritation of the throat, salivation, warmth at the epigastrium, lightness of the head, dizziness, buzzing in the ears, headache, numbness, a dusky countenance, staggering, constriction of the chest, palpitation of the heart, a frequent or abnormally slow pulse, weariness, and drowsiness. Poisonous but not fatal doses have produced the following effects: insensibility, usually a feeble pulse, dilated pupils, a turgid and dusky face, heat of head, convulsions or rigidity, or both in succession, but no paralysis. Consciousness and muscular power return rapidly, considering the gravity of the initial symptoms. In fatal cases it is remarkable that there are no convulsions, but relaxation rather. The pupils are usually dilated and the eyes lustrous, and the pulse sometimes grows slower until extinction. After death the skin is purplish and all the internal veins are gorged with blood which is dark and uncoagulated. The eyes retain their peculiar glistening aspect. The mucous membrane of the stomach is usually congested.

Medical Uses.—The dangerous potency of this acid necessarily restricts its use in medicine. It has been employed with a certain advantage in the treatment of *whooping cough*, but is at best a palliative merely. The same may be said of its influence in cases of purely nervous cough, spasmodic *dysphagia*, and *angina pectoris*. It is related that in a case of the *night cough of children* which had resisted every other treatment the attacks ceased almost abruptly on the administration of this acid in doses of from one-half to three-quarters of a minim every 3 hours (Macdonald). In *gastralgia* there is perhaps more reason to anticipate advantage from its use, and, as the disease is often rebellious, the possibility of relieving it by prussic acid should not be overlooked. Most of the cases supposed to illustrate its efficacy were clearly not examples of pure *gastralgia*, but of painful dyspepsia, and very possibly instances of gastric ulcer were included among them. Probably in all the element pain was most beneficially influenced; in some, vomiting was palliated or arrested. These effects appear to indicate an anæsthetic action in the acid, which is more distinctly manifested by the topical use of the medicine in various diseases of the skin in which tingling, itching, and other distressing sensations exist.

The average dose of diluted hydrocyanic acid is 2 or 3 minims (Gm. 0.10–0.20), given several times a day in some neutral vehicle with the addition of a few drops of alcohol. It should be dispensed in vials covered with black paper or varnish, to prevent the decomposing action of the light; and a minimum dose should be directed when a fresh prescription is made. From 30 minims to a fluidrachm (Gm. 2–4), in a fluidounce (Gm. 32) of distilled water or rose-water, forms an appropriate lotion, which, however, should not be applied to the skin unless it is perfectly unbroken.

Although the experiments of Preyer upon guinea-pigs demonstrate that hydrocyanic acid and atropia are mutually antidotal when given simultaneously or in quick succession, and in duly-proportioned doses, it is nevertheless practically true that as regards man there is no antidote to the poisonous action of hydrocyanic acid. The most efficient remedy consists in the stimulation produced by the shock of cold water dashed at intervals upon the chest and spine. Subordinate in efficiency, but not to be neglected, are the application of ammonia to the nostrils, the stimulus of induced electricity, artificial respiration, and the judicious agitation of the patient.

ACIDUM HYDROFLUORICUM.—HYDROFLUORIC ACID.

Acidum fluorhydricum.—Hydrogen fluoride, E.; *Acide fluorhydrique*, *Acide phlorique*, Fr.; *Fluorwasserstoffsäure*, G.

Formula HF. Molecular weight 20.

Origin.—Fluorine exists in nature in combination with calcium as *fluor-spar*, also in *cryolite* (kryolite) and other minerals; small quantities of fluorine have been found in some mineral and potable waters, in bones, and in the ashes of various plants. The use of fluor-spar for etching on glass was known in the seventeenth century, but hydrofluoric acid was discovered by Scheele (1771), and first prepared pure by Gay-Lussac and Thénard (1808).

Preparation.—Powdered fluor-spar (or cryolite) which is free from silica is heated with sulphuric acid in a retort of platinum or lead, and the gas is conducted into distilled water contained in a well-cooled receiver of the same metal. Great caution is necessary to prevent contact with the vapors and avoid inhaling them.

Properties.—Pure hydrofluoric acid forms a thin, colorless fuming liquid which is lighter than water, does not solidify at -35° C. (-31° F.), boils at 19.4° C. (67° F.), and is freely soluble in water. The aqueous solution, which is sometimes called *fluoric acid*, *acide fluorique*, is heavier than water; a solution having the density 1.15 contains 35.37 per cent. HF, and boils constantly at 120° C. (248° F.) (Bineau). Like the pure acid, it is extremely caustic, and causes severe ulceration when applied to the skin. It corrodes glass and attacks most organic and inorganic compounds, but does not act upon paraffin; it is best preserved in bottles made of lead or of gutta-percha.

The element *fluorine*, owing to its intense affinities for other elements, has not been obtained in a pure state; it appears, however, to be gaseous, and to possess an odor resembling that of chlorine.

Uses.—Hydrofluoric acid in the gaseous state and its aqueous solution are used for etching glass. *Ammonium fluoride* has a similar effect; it forms white or colorless scales or prisms, which are deliquescent and should be kept in a gutta-percha bottle. According to F. L. Slocum (1880), a mixture suitable for writing on glass, like that sold at one time as *diamond ink*, is made by mixing barium sulphate 3 parts, ammonium fluoride 1 part, and sulphuric acid sufficient to form a semifluid mixture; if kept in glass this should be coated on the inside with paraffin, wax, or gutta-percha.

Medical Uses.—Hydrofluoric acid was used by Woakes in twenty cases of *goitre*, of which seventeen are said to have been cured. The acid was given in doses of from 15 minims to 1 drachm, thrice daily, largely diluted with water. It is true that injections of iodine and the administration of iron and bitter tonics formed part of the treatment (*Lancet*, 1881, i. 497). Dr. Da Costa concluded from clinical observation that the fluorides are prompt emetics without depressing, and relieve pain without producing sleep. But they readily derange the stomach, and even in small doses produce anorexia (*Med. Record*, xx. 168). This acid has been applied as a caustic.

ACIDUM LACTICUM, U. S., P. G.—LACTIC ACID.

Isolactic, *Ethidene-lactic*, or *Oxypropionic Acid*, E.; *Acide lactique*, Fr.; *Milchsäure*, G. Formula $\text{HC}_3\text{H}_5\text{O}_3 = \text{CH}_3\text{CHOH.COOH}$. Molecular weight 90. Strength 75 per cent. Sp. gr. 1.212.

Origin.—Lactic acid was discovered by Scheele (1780) in sour milk, in which it results from the spontaneous fermentation of the sugar of milk under the influence of the casein; $\text{C}_{12}\text{H}_{24}\text{O}_{12}$ (milk-sugar) yields $4\text{HC}_3\text{H}_5\text{O}_3$ (lactic acid). This transformation of the former into the latter is called the *lactic fermentation*. A similar change is produced in dextrin, glucose, cane-sugar, etc. by the action of casein and other protein compounds; lactic acid is therefore met with in many vegetable products which have turned

sour. T. and H. Smith's *thebolactic acid* of opium is identical with the lactic acid of milk; but the *sarcolactic acid* of meat-juice, discovered by Berzelius (1807), and recognized by Liebig as differing in several respects from the lactic acid of milk, consists of two acids, one of which, known as *paralactic acid*, has the composition given above, but is dextrogyre, and the solutions of its salts have a levogyre action. The second lactic acid of flesh is like that of milk, optically inactive, but is *ethnelactic acid*, having the composition $\text{CH}_2\text{OH}.\text{CH}_2.\text{COOH}$, and its zinc salt is soluble in absolute alcohol. Strecker (1858) observed that by heating sarcolactic acid for some time to 130° or 140° C. (266° or 284° F.) the anhydride is produced, which, dissolved in boiling water, yields ordinary lactic acid. During lactic fermentation, alcohol, several acids, a peculiar gum, and mannit are formed in variable proportions, more particularly if the temperature be allowed to vary much from about 45° C. (113° F.).

Preparation.—100 parts of sugar are dissolved in sufficient water to yield a solution of 8° or 10° B.; 8 or 10 parts of fresh cheese and 50 parts of prepared chalk are added, and the mixture placed for several weeks in a sunny place, when lactate of calcium will be found crystallized (Pelouze). Boutron and Frémy dissolve 300 Gm. of milk-sugar in 4 liters of skimmed milk, expose the mixture to a temperature of from 20° to 30° C. (68° to 84° F.), and neutralize every other day with bicarbonate of sodium. When it ceases to acquire an acid reaction the liquid is boiled, filtered, and carefully evaporated to a syrupy consistence; this is dissolved in strong alcohol, the sodium precipitated by sulphuric acid, and the lactic acid converted into lactate of calcium by the addition of chalk. Wackenroder operates in the same manner, except that an excess of chalk is added before fermentation begins, and the mixture is kept at 24° C. (75.2° F.), and the lactate of calcium is recrystallized from boiling water. This salt, obtained by one of the foregoing processes, is then decomposed by an ascertained accurate amount of sulphuric or oxalic acid. If during fermentation the lactic acid is neutralized by commercial zinc-white, lactate of zinc is obtained, which may be decomposed by sulphuretted hydrogen. Lautemann, who proposed this modification (1860), followed in the main Bensch's directions, dissolving 6 pounds of cane-sugar and $\frac{1}{2}$ ounce of tartaric acid in 35 pounds of boiling water, adding after 2 days 4 ounces of old cheese diffused in 8 pounds of sour milk, and exposing the mixture to a temperature of 40° C. (104° F.). Below 20° C. (68° F.) the production of lactic acid is impeded; above 40° C. (104° F.) butyric acid begins to be formed.

A more expeditious method for the preparation of lactic acid has been described by H. Kiliani (1882): 500 Gm. of cane-sugar, dissolved in 250 Gm. of water, are converted into invert-sugar by boiling with 10 Cem. of sulphuric acid; 450 Cem. of solution, made of equal parts of caustic soda and water, are gradually added, and the mixture is heated to 60° or 70° C., until it ceases to react for sugar with Fehling's solution. The liquid is neutralized with sulphuric acid, the sodium sulphate allowed to crystallize, and the remainder precipitated by alcohol; one-half of the clear alcoholic liquid is heated, neutralized with zinc carbonate, mixed with the other half, and cooled, when zinc lactate will crystallize, from which the acid may be obtained in the usual manner.

Properties.—Official lactic acid is a syrupy, colorless or pale wine-yellow liquid, having a slight bland or no odor, a very sour taste, and the specific gravity 1.212; the pure acid is colorless, inodorous, and has the specific gravity 1.215 at 20.5° C. (68.9° F.), or, according to Mendelejeff, 1.2485 at 15° C. (59° F.). It unites in all proportions with water, alcohol, and ether, but is insoluble in chloroform, carbon bisulphide, and benzin. It forms with cold concentrated sulphuric acid a clear liquid, which on heating becomes brown and black. On warming the acid with potassium permanganate the odor of aldehyde is given off. When kept at ordinary temperature over sulphuric acid, Wislicenus (1870) obtained *dilactic acid*, an amorphous bitter anhydride of the composition $\text{C}_6\text{H}_{10}\text{O}_5 = \text{C}_3\text{H}_4\text{O}_2.\text{C}_3\text{H}_6\text{O}_3$. The same compound is formed from lactic acid at from 110° to 130° C. (230° to 266° F.), and at about 150° C. (302° F.) the anhydride *lactide*, $\text{C}_4\text{H}_4\text{O}_2$, is obtained in volatile, fusible rhombic plates. Both anhydrides are insoluble in water, but on prolonged boiling with it, or more rapidly by dissolving in alkaline liquids, yield lactic acid. When distilled at a higher temperature or when heated in the open air, lactic acid decomposes, giving off a suffocating odor and leaving a spongy charcoal, which is finally completely consumed. It coagulates milk and albumen, and displaces carbonic and acetic acids from their compounds, yielding salts which are soluble in water, and mostly also in alcohol. Lactic acid on being oxidized by nitric acid yields oxalic acid, and by treatment with chromic acid formic and acetic acid are produced. On oxidizing ethene lactic acid large crystals of *malonic acid*, $\text{C}_3\text{H}_4\text{O}_4$, are obtained. 90 grains of the official acid are

neutralized by 75 grains of bicarbonate of potassium, or 4.5 Gm. of the acid by 37.5 Ccm. of volumetric solution of soda, indicating 75 per cent. of $\text{HC}_3\text{H}_5\text{O}_3$.

Impurities.—Treated with a hot solution of potassa, lactic acid is not materially colored; if it readily becomes brown, extractive matters are present. Dissolved in strong alcohol, gum and some mineral salts are left behind. Glycerin, glucose, mannit, tartaric acid, and most salts remain undissolved by ether. Acetic and butyric acids are recognized by their odor, which becomes more apparent on warming. For detecting other organic and mineral acids their special tests may be applied. In the diluted acid calcium salts are indicated by oxalate of ammonium; lead, by hydrosulphuric acid; zinc, after neutralization with ammonia, by sulphhydrate of ammonium; sulphuric acid, by chloride of barium; hydrochloric acid, by nitrate of silver; and oxalic acid, by chloride of calcium, after previously diluting the acid with twenty times its quantity of water and neutralizing with ammonia. On saturating the acid with zinc carbonate, and treating with absolute alcohol, zinc sarcocollate will be dissolved; also glycerin and mannit if present.

Off. Prep.—Ferri lactas, *U. S.*

Medical Action and Uses.—Lactic acid is normally secreted by the stomach, and may be detected in the sweat and urine. Its excess in the system seems to be one of the most striking phenomena of rheumatism, and several cases have been published in all of which its free administration during diabetes occasioned an attack of articular rheumatism. According to Mendel, it is hypnotic in large doses. Lactic acid has been employed in the treatment of various forms of *dyspepsia*, but chiefly in those presumed to depend upon debility of the stomach, and then as a solvent for pepsin. Some years ago Cantani suggested that, in addition to the use of an exclusively animal diet in *diabetes*, an agent ought to be employed which would prevent the waste of the tissues by furnishing an appropriate substance in their stead. For this end he proposed lactic acid, which he believed would supply the very product which the deranged liver was no longer capable of furnishing. Whatever may be thought of the theory, it appears certain that, in the hands of the physician named and in those of Dr. Balfour and Dr. Foster, several cases of diabetes treated by this medicine were improved by it more than by any other means whatever, the secretion of urine falling to the normal standard, while it became free from sugar and the patients regained their flesh and strength. From 2 to 4 drachms, diluted in from 8 to 10 ounces of water (Gm. 8–16 in Gm. 250–320), were taken during the day. The remarkable solubility of false membranes in lactic acid led to its use in *diphtheria* and in *croup* (pseudo-membranous laryngitis); and the reports of several observers appear to prove that when the acid is applied with a mop in the former, and by atomization or the syringe in the latter disease, it contributes in a remarkable degree to the cure. For the purpose last described a solution was used of 1 part of the acid in 20 parts of water.

Mendel claims that lactic acid relieves *insomnia* produced by nervous excitement, and especially by fright. He recommends that from 1 to 2 fluidrachms (Gm. 4–8) be given in lemonade, or that much larger doses be administered by enema; *e. g.* from 2 fluidrachms to half a fluidounce (Gm. 8–16). In such cases the acid should be neutralized by bicarbonate of sodium. The results of Maragliano's use of the medicine in the insane hardly justify a belief in its hypnotic virtues.

ACIDUM NITRICUM, *U. S., Br., P. G.*—NITRIC ACID.

Acidum nitri s. azoticum, Spiritus nitri acidus.—*Acide azotique s. nitrique*, Fr.; *Salpetersäure*, G.

Formula $\text{HNO}_3 = \text{NO}_2\text{OH}$. Molecular weight 63. Strength 69.4 per cent. (30 per cent. *P. G.*). Spec. grav. 1.42 (1.185 *P. G.*).

Diluted Nitric Acid. Strength, 10 per cent. *U. S.*, 17.44 per cent. *Br.* Spec. grav. 1.059 *U. S.*, 1.101 *Br.*

Origin.—Nitric acid occurs chiefly in combination with the alkalies and alkaline earths, and in localities where vegetable or animal matter has undergone putrefaction. It is found in the juice of many plants and in small quantities in rain- and snow-water. A process for preparing this acid was first made public by Geber in the eighth century, and its composition was determined by Cavendish (1785) and Davy (1816). For medicinal and technical purposes nitric acid is made by decomposing nitrate of sodium or of potassium by sulphuric acid.

Preparation.—1. ACIDUM NITRICUM. It is prepared on the large scale in apparatus constructed similar to that used in the manufacture of hydrochloric acid. The sulphuric

acid acts upon nitrate of potassium, forming acid sulphate of potassium and liberating the nitric acid: thus, $\text{KNO}_3 + \text{H}_2\text{SO}_4 = \text{KHSO}_4 + \text{HNO}_3$. The resulting acid salt does not decompose another molecule of potassium nitrate, except at so high a temperature that most of the nitric acid then given off will be decomposed into nitrous acid and oxygen. 1 molecule or 101 parts of potassium nitrate will therefore require 1 molecule or 98 parts of concentrated sulphuric acid. The same amount of nitric acid may be obtained from 1 molecule or 85 parts of sodium nitrate; but, according to Wittstein (1838), the sulphuric acid requires to be diluted with one-fourth its weight of water to prevent the mass in the retort from being carried over into the receiver, the foaming being prevented by supplying the acid sodium sulphate with the necessary water of crystallization. Graham showed that the reaction of acid sodium sulphate upon sodium nitrate occurs at a much lower temperature than between the corresponding potassium salts; hence, all the nitric acid may be obtained from 2 molecules or 170 parts of sodium nitrate with 98 parts of sulphuric acid, the decomposition furnishing sulphate of sodium; $2\text{NaNO}_3 + \text{H}_2\text{SO}_4$ yields $2\text{HNO}_3 + \text{Na}_2\text{SO}_4$. The violent foaming of the residue toward the close of the operation is prevented by the addition of a little water or by the use of weaker sulphuric acid. Stieren recommends (1865) the employment of 21 pounds of sulphuric acid, specific gravity 1.717, for 24 pounds of nitrate of sodium, as a charge for a retort of 5 or 6 gallons capacity; about one-fourth of the residue in the retort consists of acid sulphate of sodium, the remainder being neutral sulphate.

In the manufacture of nitric acid from nitrate of sodium, sulphuric acid may be replaced by manganous chloride, sulphate of iron, sulphate of magnesium, and similar salts, the metals of which remain as oxides in the retort with the sodium salt; but in most cases the heat necessary to effect the reaction is sufficient to decompose a considerable portion of the nitric acid.

As obtained on the large scale it usually contains some hyponitric acid, which imparts to it a red or yellow color. This is removed by applying to it a moderate heat, and after the red vapors have escaped the acid is diluted to the desired strength.

The nitrates of sodium and potassium, as they occur in commerce, contain variable quantities of chlorides, from which, if used in the above process, hydrochloric acid is liberated, and this, reacting with some of the nitric acid, produces chlorine, which, for this reason, may contaminate the nitric acid. If the acid is desired in a pure state, the nitrates must be previously purified by repeated recrystallization, or the impure acid rectified either by itself or over some nitrate. The first portion of the distillate contains the chlorine, and the receiver is changed when the condensed liquid ceases to produce a curdy precipitate with nitrate of silver. Iodine, if present from the nitrate of sodium, will likewise be found in this part of the distillate. The distillation is continued into the new receiver until about one-fifth or one-sixth is left in the retort, from which, if the heat is continued, hyponitric acid is again produced. Formerly the chlorine and iodine were removed from the crude acid by nitrate of silver; the acid was carefully decanted from the precipitate and rectified. The process of direct rectification, as already described, is more advantageous, from one-half to three-fourths being obtainable in the pure state, according to the purity of the crude acid used.

2. *ACIDUM NITRICUM FUMANS*, *P. G.*; Acidum nitroso-nitricum, Spiritus nitri fumans. —Fuming nitric acid, Nitroso-nitric acid, *E.*; Acide azotique fumante, *Fr.*; Rauchende Salpetersäure, *G.*

If one-half the amount of sulphuric acid is employed as stated above for the preparation of nitric acid from potassium nitrate, and the heat is finally increased until the reaction between the acid sulphate and the remaining nitrate of potassium has been completed, the distillate will be nitric acid containing a considerable quantity of hyponitric acid, or nitrogen tetroxide, N_2O_4 , and nitrous anhydride or nitrogen trioxide, N_2O_3 ; in the presence of water these two compounds may decompose, with the formation of nitric acid and of nitrous acid, HNO_2 , and nitrogen dioxide, N_2O_2 . Fuming nitric acid therefore contains, besides HNO_3 , variable quantities of lower nitrogen oxides.

3. *ACIDUM NITRICUM DILUTUM*, *U. S.*, *Br.*—Diluted nitric acid, *E.*; Acide azotique dilué, *Fr.*; Verdünnte Salpetersäure, *G.*

Mix 1 part of nitric acid with 6 parts of distilled water.—*U. S.* Dilute 6 fluidounces of nitric acid with sufficient distilled water, so that at a temperature of 60° F. it shall measure 31 fluidounces, or dilute 2400 grains of nitric acid with distilled water, so as to obtain 1 imperial pint of the mixture.—*Br.*

Properties.—1. *NITRIC ANHYDRIDE.* This was discovered by St. Clair Deville (1849) in decomposing pure crystallized nitrate of silver by absolutely dry chlorine gas.

It forms colorless shining prisms, which fuse at about 30°C . (86°F .) into a liquid boiling near 50°C . (122°F .), and deliquesces rapidly when in contact with moist air. Its composition is N_2O_5 , molecular weight 108; combining with 1 molecule of water, H_2O , it forms 2 molecules of nitric acid, 2HNO_3 .

2. **CRUDE NITRIC ACID.** As met with in commerce, it is either colorless or of a pale yellowish color, and contains the impurities mentioned above, together with a little iron. It is often called *aqua fortis*; the weaker kind is of about 1.21 specific gravity, being known as single aqua fortis, and the stronger, of specific gravity 1.37, as double aqua fortis. Crude nitric acid is extensively used in many chemical processes.

3. **PURE NITRIC ACID.** It is a colorless liquid, wholly volatilized by heat. The concentrated acid or hydrogen nitrate, corresponding in composition to the formula HNO_3 , has at 0°C . (32°F .) the specific gravity 1.559. When exposed to the light or heated to near its boiling-point, 36°C . (186.8°F .), it is decomposed partly into water and hyponitric acid, so that its boiling-point is not constant. Nor is the boiling-point of weaker acids constant. Those below and those above the specific gravity 1.42 boil at a constantly rising temperature, until the acid in the retort has been raised or lowered in strength to correspond to the formula $2\text{HNO}_3 \cdot 3\text{H}_2\text{O}$, when its boiling-point will be stationary at 121°C . (250°F .), and it will have at 15.5°C . (60°F .) the specific gravity 1.42 (Graham). This strength of nitric acid has been adopted as the official standard in the United States, British, and French Pharmacopeias. According to Roscoe, nitric acid containing between 70 and 65 per cent. of hydrogen nitrate yields, after continued boiling, a liquid the boiling-point of which is 120.5°C . (249°F .) at a barometer pressure of 735 Mm., and the specific gravity of which is 1.414 at 15.5°C . (60°F .) It contains 68 per cent. of hydrogen nitrate, while Graham's acid should contain 69.96 per cent. The existence of a definite hydrate having a constant boiling-point appears, therefore, somewhat doubtful. The strength is determined by diluting the acid with four or five times its weight of water, and neutralizing with volumetric solution of soda; 6.30 Gm. of the acid require 69.4 Cem. of the alkali (*L. S.*), or 90 grains of the former and 1000 grain-measures of the latter (*Br.*), indicating respectively 69.4 and 70 per cent. HNO_3 , or 59.96 and 60 per cent. N_2O_5 . The acid of the German Pharmacopeia is much weaker, its spec. grav. being 1.185.

Nitric acid is a powerful oxidizing agent, converting most metals into oxides or nitrates and decomposing most organic compounds. At the same time orange-red vapors are given off, which are either the trioxide, N_2O_3 , or the dioxide, NO_2 , the latter being colorless, but acquiring a deep-red color in contact with oxygen. Exposed to the direct or diffused sunlight, even if of less than the official strength, it is partly decomposed, becomes red, and then contains lower nitrogen oxides. It is monobasic and combines with most of the basylous radicals, all its compounds being soluble in water, with the exception of a few so-called basic nitrates, such as subnitrate of bismuth.

The density of pure nitric acid varies with its strength. In taking its specific gravity the absence of notable quantities of hyponitric acid should be ascertained, since they

increase the density. The foregoing table, drawn up J. Kolb (1866), agrees nearly with the older one of Ure, which is based upon a maximum density of 1.500 at 15.5° (60° F.), and an acid having, according to him, a composition represented by the formula $4\text{HNO}_3 \cdot \text{H}_2\text{O}$.

4. FUMING NITRIC ACID has a brown-red color, and when in contact with the air emits vapors of the same color, which are of a suffocating odor. It requires to be kept in a cool place, and caution should be exercised in removing the stopper, lest a portion of the liquid should be violently ejected with the escaping vapors. The German Pharmacopœia requires for this preparation a specific gravity of from 1.45 to 1.50. The so-called *nitrous acid* of our commerce is a similar but weaker article, consisting of nitric acid, which is colored red by variable quantities of hyponitric acid. If nitrous acid gas, N_2O_3 , is conducted into nitric acid, a corresponding quantity of hyponitric acid, N_2O_4 , is formed; thus: $\text{N}_2\text{O}_3 + 2\text{HNO}_3 = 2\text{N}_2\text{O}_4 + \text{H}_2\text{O}$. This compound is colorless at -10°C . (14°F .), orange-red at 10°C . (50°F .), and darker red above this temperature.

5. DILUTED NITRIC ACID is colorless, has the specific gravity 1.059, and 12.6 grains of it are neutralized by 20 Cem. of the volumetric solution of soda, corresponding to 8.57 per cent. N_2O_5 or 10 per cent. HNO_3 , *U. S.* That of the British Pharmacopœia has the specific gravity 1.101, and 361.3 grains of it (6 fluidrachms) require for neutralization 1000 grain-measures of the volumetric solution of soda, corresponding to 14.95 per cent. N_2O_5 or 17.44 per cent. HNO_3 .

Impurities.—Such as are likely to be present have been mentioned above. Mineral impurities are left behind as a fixed residue on evaporation, and may then be recognized by appropriate tests. Iodine is detected by agitating the acid with chloroform, which will acquire a reddish color and impart to starch a blue color. If the color appears only after the careful addition of sulphuretted hydrogen, iodic acid has been present; with an excess of sulphuretted hydrogen the iodic acid would be converted into colorless hydriodic acid, $2\text{HIO}_3 + 6\text{H}_2\text{S} = 6\text{H}_2\text{O} + 2\text{HI} + 3\text{S}_2$. Diluted with 5 volumes of distilled water, nitric acid should not produce any precipitate with nitrate of silver (chlorine or hydrochloric acid), nitrate of barium (sulphuric acid), or sulphuretted hydrogen, either before or after neutralization with ammonia (metals). The diluted acid should not be colored blood-red by sulphocyanide of potassium (iron) or blue by starch-paste (iodine). Traces of arsenic are best detected by Fleitmann's test (see page 28), and the lower nitrogen oxides by the decolorization of solution of potassium permanganate or the liberation of iodine from solution of potassium iodide. As stated above, such lower oxides are formed on exposure to sunlight.

Pharmaceutical Uses.—Nitric acid is largely used for dissolving metals (bismuth, iron, mercury, and silver), for the oxidation of ferrous to ferric compounds and of phosphorus to phosphoric acid, and in the preparation of nitrous ether and nitrite of amyl.

Physiological Action.—When injected into the blood-vessels of animals it is said not to coagulate the blood, or to do so very imperfectly. Upon the tissues with which the strong acid (33 per cent.) comes in contact it exerts a caustic action, staining the skin yellow, rendering the pharynx and œsophagus white, and causing erosions and ulcers, some of the latter perforating, in the stomach. The small intestine is generally intact, but the glands of the large intestine are ulcerated, showing, perhaps, the excretion of the acid partly through them. A 10 to 15 per cent. solution does not stain the tissues, but produces swelling, œdematous or hæmorrhagic, and gives the blood of the part a brownish tint. If medicinal doses are long continued, unless precautions are taken the acid impairs and may destroy the enamel of the teeth. It increases the appetite and augments the secretion of urine. A white coating generally covers the tongue; the mouth at first grows dry, but later the salivary secretion may become profuse, when the gums grow spongy and bleed, and the teeth ache and are loosened. If continued, it occasions dyspepsia, colic, foul breath, headache, feverishness, debility, and derangement of the bowels. These symptoms are said to be occasioned by nitric acid baths as well as by the internal use of the acid. They rapidly subside when the medicine is suspended.

Medical Uses.—Formerly used as a *disinfectant*, it was abandoned on account of the irritating quality of its fumes and of the introduction of chlorine and various other more efficient and less annoying agents. It was given internally in *typhus* and other low types of *fever* with presumed, but by no means demonstrated, advantage. In periodical, and especially *intermittent*, fevers, it has been proved to be one of the most efficient substitutes for cinchona, and indeed to cure many cases in which quinine was inoperative. From 6 to 8 drops of the acid, properly diluted, should be given every 6 hours without regard to remissions or exacerbations. It was formerly used in the treatment of *dysentery* and other bowel affections on the recommendation of Hope, who employed nitrous acid mxxx , and

laudanum ℞xx, in camphor-water fʒiv. of which mixture a tablespoonful was given every 2 hours. At one time it enjoyed a certain reputation in *whooping cough*, for which very large doses were administered. As far as it did good, the effect was probably due to the stimulant and substitutive action of the acid upon the fauces. By the same agency it doubtless palliates the cough of *bronchitis* and *hoarseness* due to over-exertion of the voice; it also promotes the cure of syphilitic and other *ulcers* of the throat. When used long enough to excite ptyalism it is reputed to have cured constitutional *syphilis*. In the last-named disease it has been seldom prescribed since the introduction of iodide of potassium. It would seem to allay the thirst of *diabetes*, and the daily administration of from 1 to 3 or 4 drachms of the acid in a quart of water has certainly cured several cases of *diabetes insipidus* (Kennedy). This treatment should be persevered in until the affection of the mouth produced by the medicine, and above described, is distinctly developed. In chronic enlargement of the *liver* in scorbutic, strumous, and syphilitic subjects, as well as in *jaundice* depending upon hepatic congestion, and in *scrofula* of the lymphatic glands, it appears to have been often efficacious. In chronic *impetigo* it has sometimes proved successful when other medicines were ineffectual. Externally, nitric acid has been much employed as a caustic for the *bites of rabid animals, poisonous serpents and insects*, etc. As already intimated, it forms an excellent ingredient of gargles for the treatment of syphilitic and other obstinate *ulcers* of the throat, as well as for sloughing sores in the mouth. It is an efficient application to ulcerated gums produced by mercury. In both of the last-mentioned cases it has been superseded by chlorate of potassium. Commercial nitric acid has been applied (T. G. Thomas) to ulcers of the rectum in *chronic dysentery*. The patient should first be etherized, the bowel exposed by means of a duck-bill speculum, and commercial nitric acid lightly applied by means of a small piece of wet cotton wrapped around the end of a whalebone rod. This method was used in imitation of a similar application of nitrate of silver. Lotions or foot-baths containing nitric acid are useful in the treatment of *chilblains*, and general baths feebly acidulated by its means have been recommended for *infantile jaundice*. It is a very useful application to *periostoses* when used so as to maintain a slight irritation of the skin; and as a caustic it is often resorted to for the destruction of *warts*, venereal and non-specific, and of *condylomata* and *hæmorrhoids*. For these purposes its action should be limited to the diseased structure by means of cerate; or lint saturated with concentrated nitric acid, and adapted to the part in shape and size, may be allowed to remain in contact with it for a sufficient time. The tissue may have its sensibility blunted by carbolic acid, by rhigolene or other anæsthetic vapor, or by cold; or the patient may be etherized during the operation. In *caries* of the bones and *sloughing* of the soft parts the acid may be used to hasten the separation of the diseased tissue. The *dose* of the stronger acid is from 5 to 20 minims (Gm. 0.30–1.30), and of the diluted acid from 25 to 50 minims (Gm. 1.60–3.30), three or four times a day, largely diluted. It should always be taken through a glass tube, and immediately afterward the mouth should be washed with a solution of bicarbonate of sodium.

ACIDUM NITROHYDROCHLORICUM, U. S.—NITROHYDROCHLORIC ACID.

Acidum chloro-nitrosum, Acidum nitromuriaticum, Aqua regia, Aqua regis.—Nitromuriatic acid, E.; *Acide chloro-azotique s. chloro-nitreuse, Eau régale*, Fr.; *Salpetersalz-säure, Königswasser*, G.

Preparation.—Take of Nitric Acid 4 parts (1 oz. av. = 5½ fluidrachms); Hydrochloric Acid 15 parts (3¾ oz. av. = 25 fluidrachms). Mix the acids in an open glass vessel, and when effervescence has ceased pour the product into glass-stoppered bottles, which should not be more than half filled, and keep them in a cool place.—U. S.

The French Codex directs 1 part of nitric acid, spec. grav. 1.32, and 3 parts of hydrochloric acid, spec. grav. 1.17. This preparation has been dismissed from the new German Pharmacopœia.

ACIDUM NITROHYDROCHLORICUM DILUTUM, U. S., Br.—DILUTED NITROHYDROCHLORIC ACID.

Acidum nitromuriaticum dilutum.—Diluted nitromuriatic acid, E.; *Acide chlorazotique dilué*, Fr.; *Verdünnte Salpetersalzsäure*, G.

Preparation.—Take of Nitric Acid 4 parts (1 oz. av.); Hydrochloric Acid 15 parts (3¾ oz. av.); Distilled Water 76 parts (19 oz. av. = 18½ fluidounces). Mix the acids in

a capacious open glass vessel, and when effervescence has ceased add the distilled water. Keep the product in glass-stoppered bottles in a cool place.—*U. S.*

According to the British Pharmacopœia, 3 fluidounces of nitric acid are mixed with 4 fluidounces of hydrochloric acid, and allowed to remain for a day in a bottle the mouth of which is partially closed; 25 fluidounces of distilled water are then added in successive portions, the bottle shaken after each addition, and the mixture is preserved in a stoppered bottle.

On mixing nitric with hydrochloric acid a decomposition takes place, resulting in the liberation of chlorine and the formation of water and chlorinated nitrogen oxides. This preparation has received the name of *aqua regia* from its property of dissolving gold, the king of metals, which is due to the presence of free chlorine; for the same reason are dissolved platinum, calomel, and all other metals and compounds which yield soluble chlorides. Its activity therefore depends upon the amount of free chlorine contained in it. The British Pharmacopœia employs the two acids very nearly in the proportion of 6HNO_3 to 5HCl , while the proportion directed by the *U. S. Pharmacopœia* is 1HNO_3 to 3HCl . The chlorinated compounds formed in the two processes must therefore differ to some extent; in the latter case the reaction may take place as follows: $\text{HNO}_3 + 3\text{HCl} = \text{Cl}_2 + \text{NOCl}$ (chloronitrous acid) $+ 2\text{H}_2\text{O}$, or according to this equation: $2\text{HNO}_3 + 6\text{HCl} = \text{Cl}_2 + 2\text{NOCl}_2$ (chloro-hyponitric acid) $+ 4\text{H}_2\text{O}$. A third compound, *chloronitric acid* or *nitrylic chloride*, NO_2Cl , is likewise formed, particularly if a larger proportion of hydrochloric acid be used; it is a yellow liquid, boiling at 5°C . (41°F .), and decomposed by water into nitric and hydrochloric acids. *Chloronitrous acid* or *nitroxylic chloride* is a yellowish-red liquid which boils at -5°C . (23°F .), and with water yields hydrochloric and nitrous acids. Gay-Lussac, its discoverer, described the *chloro-hyponitric acid* as boiling at -7°C . (19.4°F .), forming a lemon-yellow gas, and with water decomposing into hyponitric and hydrochloric acids. According to the older views, nitromuriatic acid is essentially a mixture of chlorine and hyponitric acid, NO_2 , the reaction being explained as follows: $\text{HCl} + \text{HNO}_3 = \text{Cl}_2 + \text{NO}_2 + \text{H}_2\text{O}$.

As the stability of these compounds is influenced by temperature and by water, it is obvious that the composition of nitromuriatic acid must vary with the proportion and the strength of the acids employed, and with the temperature at which they have been mixed; at a low temperature this mixture may be kept without evolution of gas, but at ordinary or a somewhat elevated temperature a variable mixture of gas is given off, hence the necessity of not dispensing this preparation until after effervescence has ceased, and of keeping it in vials not quite filled.

Properties.—Nitrohydrochloric acid is a liquid having a deep golden-yellow color and the odor of chlorine. It readily dissolves gold-leaf, liberates iodine and bromine from their salts, and is wholly volatilized by heat. It should be kept in a cool and dark place, and dispensed in dark- or yellow-colored bottles. It should not be kept on hand for a long time, and is preferably made extemporaneously, provided that the reaction between the acids has been completed and the effervescence has ceased before it is dispensed.

In the diluted nitrohydrochloric acid the chloronitrous acid has probably been decomposed by the water into hydrochloric and nitrous acids; thus: $2\text{NOCl} + \text{H}_2\text{O} = 2\text{HCl} + \text{N}_2\text{O}_3$. On account of the free chlorine contained in it, it should likewise be kept in a cool place and protected from the light.

Physiological Action.—Like its constituent acids, it acts as a powerful corrosive poison when taken pure and in large quantities. In smaller doses it is very apt to disagree with the stomach, and it readily attacks the enamel of the teeth. When mixed with the water of a warm bath, so as slightly to acidulate it, it is absorbed by the skin, greatly increasing the acidity of the urine, and after several repetitions of the bath exciting a burning sensation in the mouth and throat, a considerable flow of saliva, superficial ulcers of the mouth, and redness and swelling of the gums. The bowels are more frequently moved, and there is sometimes an increased tendency to urination. The secretion of bile is said also to be augmented. From an experiment upon a dog performed by Rutherford he concluded that dilute nitromuriatic acid is “a hepatic stimulant of considerable power.”

Medical Uses.—Diluted nitrohydrochloric acid has been employed for many of the same purposes as nitric acid, such as diseases of the *liver*, *scrofula*, *syphilis*, *cutaneous affections*, and chronic *rheumatism*, but there does not appear to be any sufficient ground for preferring it to the simpler nitric or muriatic acid, at least as an internal medicine. As originally used, it was applied in the form of a general warm bath which contained no less than 32 fluidounces of the acid. A foot- and a sponging-bath of like strength

were also employed, and several folds of flannel immersed in the liquid of the bath were wrapped around the body. The use of this regimen for at least 2 months was recommended. At the present time the literal application of nitrohydrochloric baths is seldom resorted to, but there is good reason to believe that in a much less energetic form they are sometimes of marked utility. Foot-baths and lotions, as well as cloths wet with acidulated water applied over the hepatic region, we have several times employed with decided advantage in cases of slight *jaundice* accompanied with *dyspepsia*, hepatic tenderness and fulness, and hypochondriasis in persons who use alcohol to excess.

The risk of its injuring the teeth should render physicians very circumspect in the internal use of this acid; and fortunately there are no conditions in which it is appropriate that cannot as well be treated by safer medicines. The *dose* of the stronger acid is 3 or 4 drops (Grm. 0.20–0.25), and of the diluted acid from 10 to 20 drops (Grm. 0.60–1–30), largely diluted and imbibed through a glass tube. The antidotes are the same as those employed for its component acids.

ACIDUM OLEICUM, U. S.—OLEIC ACID.

Acidum oleicum s. clainicum.—*Elaic acid*, E.; *Acide oléique*, Fr.; *Oelsäure*, G.

Formula $\text{HC}_{18}\text{H}_{33}\text{O}_2 = \text{C}_{17}\text{H}_{33}.\text{COOH}$. Molecular weight 282.

Origin and Preparation.—Oleic acid exists as triolein in most of the solid and non-drying liquid fats. It was isolated by Chevreul (1811), and by Gottlieb (1846) obtained in the chemically pure state.

Large quantities of oleic acid are obtained in the manufacture of stearic acid for candles. (See OLEA PINGUIA.) This acid is usually of a brownish-yellow or red-brown color, and not entirely transparent at a temperature of 12° or 15° C. (53° or 59° F.), in consequence of the presence of solid fatty acids, which, according to Ch. Rice (1873), may be mostly removed by cooling to 4.5° C. (40° F.) and subjecting the soft mass to pressure; or the acid may be mixed with an equal bulk of strong alcohol, and the solution kept at a temperature of 7° or 8° C. (45° F.), when most of the solid fatty acids will be deposited, and the oleic acid may be further purified by combining with lead and treating as stated below.

Bromeis (1842) obtained oleic acid by saponifying almond or olive oil with potassa, decomposing the soap with hydrochloric acid, combining the fatty acids with lead by digesting with oxide of lead, dissolving the oleate of lead in ether, and agitating the ethereal solution with hydrochloric acid. This process has been improved by Dr. L. Wolff (1877, 1879), by saponifying almond oil directly with oxide of lead, and substituting petroleum benzin for ether, which dissolves the lead oleate equally well. After decomposing this solution with dilute hydrochloric acid the benzin is evaporated and the remaining oleic acid washed with water.

C. T. George (1881) recommends dry white Castile soap, of which 30 parts are dissolved in 100 parts of hot water; the solution is decomposed by slowly adding, with constant stirring, 6 parts of sulphuric acid; the oily layer is washed with warm water, combined with 2 parts of powdered litharge, the warm lead oleate dissolved in 10 parts of petroleum benzin, and this solution decomposed by 1 part of hydrochloric acid diluted with 12 parts of water; after evaporating the benzin, about 15 parts of oleic acid are left.

To free oleic acid thus obtained from the products of oxidation, Bromeis recommends cooling it slowly to about –6.6° C. (20° F.) and expressing it in thin layers between absorbent paper; after repeating this several times it is remelted, a little alcohol added, cooled as before, and again expressed.

Properties.—Pure oleic acid is a colorless, inodorous, and tasteless oily liquid of neutral reaction, having at 19° C. the density .898 (Chevreul), congealing to a white crystalline mass at 4° C. (39.2° F.), and crystallizing from alcohol in dazzling white needles melting at 14° C. (57.2° F.) (Gottlieb). The solid acid is but little affected by exposure to air, but in the liquid state it rapidly absorbs oxygen on exposure, becoming yellow and brown and acquiring a rancid odor, lower congealing-point, and an acid reaction. Commercial oleic acid is somewhat oxidized, and has a yellow or brownish color, a fatty odor, and a distinct acid reaction. It may be distilled *in vacuo* without decomposition, but if distilled in contact with air yields carbonic acid, hydrocarbons, and an oily distillate containing *sebacic acid*, $\text{C}_{16}\text{H}_{31}\text{O}_4$. With melted potassa it is decomposed into palmitic and acetic acids. It is a solvent for fats and fatty acids, is insoluble in water, and dissolves in all proportions of alcohol, ether, chloroform, benzin, and other hydrocarbons, volatile and

fixed oils. It unites with bases, and when heated slowly decomposes the alkaline and earthy carbonates, forming soaps. Many of the oleates are soluble in alcohol, several also in ether; the normal lead oleate is white, melts at 80°C . (176°F .), and dissolves in ether and benzin. Oleic acid left in contact with nitrous acid is converted into the isomeric *elaidic acid*, which crystallizes in pearly plates and melts at 44°C . (111.2°F .). When oxidized by nitric acid, succinic and several other acids are obtained.

Impurities.—The solution of oleic acid in an equal weight of alcohol should at 25°C . (77°F .) be perfectly transparent and not separate a layer of fixed oil, and at 7.2°C . (45°F .) should not yield a crystalline deposit of stearic or palmitic acid.

Pharmaceutical Uses.—For the preparation of Oleata.

Medical Uses.—Oleic acid is used in medicine only in combination. Two of its compounds are officinal, but many others have been employed, especially since attention was called to them by Marshall in 1872. It is claimed that they will not decompose like ointments, and do not act as irritants on the skin. They are also more cleanly in their application, and are credited with penetrating the skin more deeply than ointments. Marshall claims for the oleates of morphia and atropia a powerful action in allaying *pain* and *nervous irritation*, and for the oleate of mercury special advantages in the treatment of diseases of the skin, including *sycosis*, *chloasma*, *pediculi*, *syphilitic* affections, etc. Dr. Shoemaker (*Trans. Med. Soc. of Penna.*, xii. pt. ii. p. 709) confirms these statements, and claims that oleate of atropia has a marked influence in *seborrhœa* and *erysipelas*, and that oleate of mercury is an invaluable application to the scalp in general thinning and *loss of hair*. Of oleate of lead he states that he has obtained remarkably good results from its use in *eczema*, in *acne rosacea* after depletion of the parts, in *burns*, and in *erythema*. Oleate of copper he found capable of rapidly curing *ringworm* of the scalp and body; and he used it for *indolent ulcerating surfaces*, as well as on hard and horny *warts*, *corns*, and *bunions*. Oleate of aluminium he used in checking muco-purulent discharges in *eczema*, and as a dressing in foul *ulcers*, *abscesses*, *sinuses*, *burns*, and *scalds*. Oleate of bismuth he found efficacious in superficial *erysipelas* and *sunburn*, and, applied by means of a bougie, in *gleet*, and oleate of arsenic in *lupus*, *epithelioma*, *warts*, and various similar growths. Oleate of silver, in the form of a fine powder or in an ointment, was valuable in the treatment of chronic *ulcers*, *bed-sores*, *eruberant granulations*, etc. In most of these cases the oleate was associated with lard in varying proportions (*Philad. Med. Times*, xii. 758).

ACIDUM OXALICUM.—OXALIC ACID.

Acide oxalique s. carbonéux, Fr.; *Oxalsäure*, *Kleesäure*, G.

Formula $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O} = (\text{COOH})_2 \cdot 2\text{H}_2\text{O}$. Molecular weight 126.

Origin and Formation.—Oxalic acid occurs in combination with ammonium in guano, and with calcium in a large number of plants, among which may be mentioned the following officinal drugs: rhubarb, curcuma, ginger, squill, orris, valerian, quassia, etc. It is found as acid potassium oxalate in the leaves and stalks of phytolacca, belladonna, and several species of rumex (sorrel), rheum, and oxalis (wood-sorrel), taking its name from the last-named genus. Some urinary calculi consist of oxalate of calcium, which is also found in the gall-bladder, in uterine mucus, and in some urinary sediments, in most lichens, and in many vegetable tissues. It is formed by the action of nitric acid upon many organic compounds, and sugar, gum, sawdust, and other organic bodies yield oxalates when gradually heated to redness with excess of potassium or sodium hydrate (Gay-Lussac, 1829). The chemical behavior of salt of sorrel was investigated by Savary (1773), and its acids recognized by Wiegleb (1779) as being distinct from others then known. Scheele (1776) prepared the acid from sugar, and proved (1778) it to be identical with that in sorrel, rhubarb, and other plants.

Preparation.—1 part of sugar, molasses, or starch is mixed in a retort with 8 parts of nitric acid, spec. grav. 1.38; a gradually increased heat is applied until the liquid finally boils, and red nitrous acid vapors cease to be given off; it is then concentrated by evaporation to one-sixth of its volume and set aside to crystallize. The crystals are drained from the mother-liquor and recrystallized from hot water. This is the process of Scheele and Bergman (1776), modified in the strength of nitric acid by Schlesinger (1841). L. Thompson (1848) recommended the use of a weaker nitric acid, of 1.245

FIG. 7.

Crystal of Oxalic Acid.

density, in order to avoid the generation of formic acid by the decomposition of oxalic acid. Schlesinger obtained from 100 parts of sugar 58 to 60 parts of handsomely crystallized oxalic acid; Thompson, from the same quantity of sugar, 63 parts of acid, and, by utilizing the mother-liquor in each subsequent charge of the retort, from 107 to 115 parts of oxalic acid. If the nitric acid employed is insufficient in quantity, a corresponding amount of the sugar will be converted into *saccharic acid*, $C_6H_{10}O_8$.

E. Stieren (1865) used the dark mother-liquors obtained in the preparation of tartaric acid as a source for oxalic acid. They are advantageously worked up for this purpose by adding to 20 parts thereof, previously warmed, 2 parts of nitric acid, spec. grav. 1.33. After the extrication of the nitrous acid vapors more nitric acid is gradually added until red vapors are no longer given off. The liquid is suitably concentrated and crystallized, and the crystals are purified by recrystallization.

Most of the oxalic acid is made by a process based upon Gay-Lussac's observations, mentioned above. Dale observed that caustic soda would not produce it from sawdust until it was mixed with potassa. 2 molecules of the former and 1 of the latter are dissolved in water to form a solution of 1.35 spec. grav., which is mixed with sufficient sawdust to obtain a pasty mass, and then heated, with constant stirring, upon iron plates. After it has been kept at a temperature of 204.5°C . (400°F .) for 1 or 2 hours, the heat is extended until the mass is quite dry, care being taken that no charring takes place. The gray powder contains 28 to 30 per cent. of oxalic acid combined with the alkalies; it is washed with solution of carbonate of sodium, by which the potassium is removed as carbonate; the oxalate of sodium is boiled with milk of lime, whereby caustic soda and oxalate of calcium are formed, and the latter is decomposed by sulphuric acid; the oxalic acid is purified by recrystallization. By this process sawdust yields about half its weight of oxalic acid (*American Journal of Pharmacy*, 1863, p. 359). 323,366 pounds of oxalic acid were imported into the United States in 1867, and over 1,000,000 pounds in 1880.

For analytical purposes oxalic acid requires purification by several recrystallizations from distilled water; this acid is dissolved in hot alcohol, the solution filtered and allowed to crystallize; the crystals, containing ethyloxalate, are boiled with water, the solution on cooling yielding the pure acid.

Properties.—Oxalic acid crystallizes from its aqueous solution in flat, oblique, rhombic prisms, which are colorless, transparent, not deliquescent, inodorous, of a strongly acid taste and reaction, and soluble in about 8 parts of water at ordinary temperature, and in nearly all proportions of boiling water. Nitric acid increases their solubility in cold water. They dissolve in $2\frac{1}{2}$ parts of cold and 1.8 parts of boiling strong alcohol, and are but little soluble in ether. Oxalic acid fuses at 98°C . (208.4°F .), and at about 160°C . (320°F .) sublimes partly unaltered, and is partly decomposed into carbonic anhydride and carbonic oxide without leaving any residue. The same decomposition takes place when oxalic acid is heated with strong sulphuric acid, but when dissolved in the latter at a moderate heat large oblique octahedra of anhydrous oxalic acid are gradually deposited (Villiers, 1880). The commercial acid usually leaves upon platinum-foil a little charcoal, which is finally consumed, a small residue of alkaline carbonate often remaining. Heated with glycerin to a little above the temperature of boiling water, it is decomposed into carbonic and formic acids. In chemical affinity it is one of the strongest acids, yielding normal and acid salts which, with the exception of the normal alkaline oxalates, are mostly insoluble or slightly soluble in water, but which dissolve in diluted nitric acid. Oxalic acid yields with lime-water, and the soluble oxalates with all soluble calcium salts, a white precipitate which is insoluble in oxalic and acetic acids. The acid potassium oxalates are popularly called *salt of sorrel*, also *salt of lemon*, and are employed for removing iron stains from paper, linen, leather, etc.; but at present oxalic acid is usually substituted for this purpose.

The composition of oxalic acid, dried at 100°C . (212°F .) or obtained by sublimation, is expressed by the formula $C_2H_2O_4$; crystallized from water, it is $C_2H_2O_4 \cdot 2H_2O$.

Impurities.—Mineral impurities are left behind on incinerating the oxalic acid upon platinum-foil; organic impurities will blacken concentrated sulphuric acid on boiling. Sulphuric acid, if present, will produce with nitrate of barium a white precipitate which is insoluble in diluted nitric acid.

Pharmaceutical Uses.—As a test for calcium salts and for preparing ferri oxalas.

Poisonous Action.—From its resemblance to Epsom salt many cases of poisoning by oxalic acid have occurred. Its taste is intensely sour; when swallowed, it, in general, soon occasions vomiting, with burning pain and constriction of the throat and stomach;

the ejected matters are dark-colored, and may contain blood. When the pain is very severe collapse may speedily ensue, with drowsiness or stupor. Sometimes these symptoms are unaccountably delayed. For several days the urine abounds in oxalates. In some cases death is rapid, occurring in from 3 to 20 minutes; in others it has been postponed until the 23d day; in others still an excessive dose has been promptly vomited, and, after comparatively slight symptoms, the patients have recovered. The quantity of the acid fatal to life is equally indeterminate. The usual *post-mortem* lesions are: dark discoloration of the œsophagus and stomach, gelatiniform softening of the mucous membrane, and even perforation of the coats of the stomach. The blood is said to present an unusually bright color. The uriniferous tubes are filled with oxalates (Fraenkel). The appropriate antidote to this poison is lime in the form of powdered chalk mixed with water. If this is not at hand, slaked lime, as dried whitewash, may be resorted to until the better preparation can be procured. Binoxalate of potassium causes similar symptoms, which require the same treatment as those of oxalic acid. Oxalic acid and the oxalates appear to be poisonous through a special action upon the nervous system and the blood, as well as by producing gastro-intestinal inflammation; but Koch ranks it with the potassium salts as a heart-poison (*Archiv f. Exp. Pathol.*, etc., xiv. 153).

Uses.—According to Cornilleau (*Practitioner*, xxv. 486), a secret remedy for diphtheria which had proved very successful was found to contain oxalic acid in combination with potash and traces of tannin. He accordingly used the following: Oxalic acid Gm. 1.50; infusion of green tea Gm. 120; syrup of bitter orange-peel Gm. 30; of which mixture a dessertspoonful was given every 3 hours. Each dose would therefore contain about three-quarters of a grain of oxalic acid. The alternative method suggested by him—viz. a decoction of fresh sorrel-leaves—is certainly safer, and either is probably as useful as infusion of sumac-berries and other acidulous preparations used as palliatives of the throat affection in diphtheria. Eltinge reports a case of *epithelioma* of the lip cured by the application of the inspissated juice of *Oxalis acetosella*. It occasioned intense pain, lasting for half an hour (*Philad. Med. Times*, xii. 159).

ACIDUM PHOSPHORICUM, *U. S.*, *Br.*, *P. G.*—PHOSPHORIC ACID.

Acide phosphorique, Fr.; *Phosphorsäure*, G.

Official Phosphoric Acid: Formula $H_3PO_4 = PO(OH)_3$. Molecular weight 98. Strength 50 per cent. Spec. grav. 1.347, *U. S.*

Diluted Phosphoric Acid: Strength 10 per cent., *U. S.*; 13.8 per cent., *Br.*; 20 per cent., *P. G.* Spec. grav. 1.057 *U. S.*, 1.080 *Br.*, 1.120 *P. G.*

Varieties and Origin.—Phosphoric (metaphosphoric) anhydride is obtained in snow-white flakes on burning dry phosphorus in dry oxygen or atmospheric air. That this new body has a greater weight than the phosphorus from which it was prepared was noticed by Marggraf (1743); but Gay-Lussac (1772) showed this increase in weight to be due to the combination with air (oxygen). The anhydride has the composition P_2O_5 , and attracts moisture with avidity, whereby it is converted into monobasic *metaphosphoric acid*, HPO_3 , which is the formula of glacial phosphoric acid. This acid is, however, not prepared in the manner indicated, but is obtained from bones, which are the calcium compound of the tribasic *orthophosphoric acid*, H_3PO_4 , discovered by Gahn (1769) and isolated by Scheele (1771). A third modification is the bibasic *diphosphoric* or *pyrophosphoric acid*, having the formula $H_2P_2O_7$. Rother (1876) regards the following as the correct formulas: metaphosphoric acid, $H_2P_2O_6$; pyrophosphoric acid, $H_4P_2O_7$; and orthophosphoric acid, $H_6P_3O_{10}$. The three acids differ from each other in the following reactions of their aqueous solutions: *Metaphosphoric acid* coagulates albumen, and produces white precipitates with chloride of barium and chloride of calcium, and a transparent gelatinous precipitate with nitrate of silver. *Pyrophosphoric acid* does not affect albumen, chloride of calcium, or chloride of barium, but produces a white precipitate with nitrate of silver on the addition of a little ammonia. *Orthophosphoric acid* does not affect albumen, chloride of calcium, or chloride of barium, and produces with nitrate of silver a yellow precipitate on the addition of a little ammonia. The reaction of silver salts with orthophosphates was first described by Marggraf (1746), and with pyrophosphates by Clark (1828); and the difference in the behavior to albumen was noticed by Berzelius and Engelhart (1826). But the exact chemical relations of these different compounds was first explained by Thomas Graham (1833).

Phosphoric acid, met with in the combined state in the mineral, vegetable, and animal kingdom, is orthophosphoric acid. Pyrophosphates are obtained by heating to redness

orthophosphates containing 1 atom of basylous hydrogen or ammonium. (See SODII PYROPHOSPHAS.) Metaphosphoric acid is produced on heating ortho- or pyrophosphoric acid or their ammonium compounds to redness.

Preparation.—1. ACIDUM PHOSPHORICUM GLACIALE.—Glacial Phosphoric Acid, *E.*; Acide phosphorique glacial, *Fr.*; Glasige Phosphorsäure, *G.*

Formula HPO_3 . Molecular weight 80. About equal parts of bones burned to whiteness, and sulphuric acid diluted with 15 parts of water, are digested for some time until the insoluble part has been converted into white smooth sulphate of calcium; the liquid, containing sulphuric and phosphoric acids, and holding calcium and magnesium phosphates in solution, is removed by filtration and washing with water, neutralized with ammonia or carbonate of ammonium, separated from the precipitated phosphates, and evaporated to dryness. The ammonium phosphate is then heated in a platinum crucible to redness until the ammonia has been completely driven off. Porcelain capsules are corroded in this last operation. The fused acid is poured upon polished iron plates, and, when cool, put into bottles.

Thus prepared, phosphoric acid contains a little sodium, to free it from which Neustadt (1861) proposes to neutralize the acid with ammonia, precipitate with barium chloride, and decompose the resulting phosphate of barium, after it has been thoroughly washed, with sulphuric acid; the acid filtrate is then evaporated and heated to redness.

2. ACIDUM PHOSPHORICUM, U. S.—*Phosphoric Acid, E.* Phosphorus 16 parts (4 oz. av.); Nitric Acid, Distilled Water, each a sufficient quantity. Mix 100 parts (25 oz. av. = 17 fluidounces) of nitric acid with 100 parts (25 oz. av. = 24 fluidounces) of distilled water in a glass retort having the capacity of 400 parts. Having placed the retort upon a sand-bath or wire-gauze support, connect it loosely with a well-cooled receiver, and add to the acid in the retort the phosphorus, previously cut into fine pieces. Insert a funnel through the tubulure of the retort, and then gradually apply heat until the reaction is seen to commence. Regulate the heat carefully, so as to prevent the reaction from becoming too violent, or, if necessary, check it by the addition of a little distilled water through the funnel. From time to time return the acid liquid, which collects in the receiver, into the retort, until all the phosphorus is dissolved. Then transfer the liquid to a weighed porcelain capsule, and continue the heat, at a temperature not exceeding 190°C . (374°F .), until the excess of nitric acid is driven off, and an odorless, syrupy liquid remains. Test small portions for nitric, phosphorous, and arsenic acids by the methods indicated below. If nitric acid be present, evaporate the liquid until no reaction for nitric acid can be obtained. If phosphorous acid be present, add to the liquid a mixture of 6 parts of nitric acid and 6 parts of distilled water, and again evaporate until no reaction for phosphorous or nitric acid can be obtained. Then, having cooled the acid, add sufficient distilled water to make the product weigh 100 parts. If arsenic acid be present, dilute the acid with 150 parts of distilled water, heat to about 70°C . (158°F .), and pass through the liquid a stream of hydrosulphuric acid gas for half an hour; then remove the heat and continue passing the gas until the liquid is cold. Close the vessel tightly, set it aside for 24 hours, filter the liquid, heat it until all odor of the gas has been driven off, again filter, and evaporate until the residue weighs 100 parts (25 oz. av. or $17\frac{3}{4}$ fluidounces). Preserve the product in glass-stoppered bottles.—*U. S.*

When phosphorus is treated with a weak nitric acid no action will take place in the cold, but at an elevated temperature it is oxidized into phosphorous and phosphoric acids, according to the strength of the acid employed. Concentrated nitric acid oxidizes it at once into phosphoric acid. The reaction, which is moderate in the beginning, rapidly becomes violent, the phosphorus is ignited, and nitrous acid vapors are so copiously disengaged that an explosion is likely to occur, particularly if the operation is performed in a retort, shattering the vessel and throwing the hot acid and burning phosphorus in all directions. The danger is avoided by the use of a diluted nitric acid, as directed above, the oxidation of the phosphorus taking place uniformly and with perfect safety when an acid of 1.20 or 1.22 specific gravity is used, or obtained by mixing equal weights of the officinal acid and distilled water. It is important, however, that a moderate heat only be applied, sufficient to fuse the phosphorus and to induce the reaction; about 50°C . (122°F .) will suffice. No advantage results from cutting the phosphorus into fine pieces, since at ordinary temperature the reaction proceeds very slowly. Considerable heat being produced by the oxidation, the subsequent heating should be carefully watched; it is unnecessary to heat the mixture to boiling until after the phosphorus has been dissolved. With nitric acid of less strength a higher degree of heat is requisite to commence and

sustain the reaction, and much nitric acid will either distil over or be lost. But even at a more moderate heat a little nitric and phosphorous acid will be vaporized, and this should be returned by keeping the neck of the retort elevated, or by pouring the liquid which may have collected in the receiver back into the retort. If the operation is skilfully performed, an inverted funnel over a capacious porcelain capsule, as recommended by Procter, commends itself for convenience and simplicity of arrangement in the place of a retort. No nitric acid will be lost by spirting, and most of that volatilized during the process will be condensed within the funnel and fall back into the capsule if the heat has not been raised too high. The operation may be considered successful if no particles of the fused phosphorus are carried to the surface of the liquid and nitrous acid vapors are regularly extricated. After the phosphorus has been completely dissolved, the funnel is removed or the liquid poured from the retort into a porcelain capsule, and the heat gradually raised to boiling, when the phosphorous acid contained in the liquid will be oxidized to phosphoric acid, red vapors being often evolved quite copiously as soon as a sufficient concentration has been attained. The amount of nitric acid ordered by the Pharmacopœia is about sufficient for oxidizing the phosphorus to phosphoric acid. But should a loss be occasioned from overheating or insufficient condensing, the liquid will contain phosphorous acid, and likewise arsenious acid in case the phosphorus was contaminated with arsenic; on applying heat, this metal will be now deposited as a black powder, and the phosphorous be oxidized to phosphoric acid, but at the same time phosphorus trihydride is given off (Liebig). To avoid this loss of phosphorus the liquid should be completely oxidized, heated to 188° C. (370.4° F.), at which temperature, according to Wittstock, all nitric acid is expelled, then diluted with water, and while warm saturated with sulphuric acid, so as to reduce the arsenic to arsenious acid, the latter being more readily precipitated as sulphide than the former. In this manner the contamination with sulphuric acid from the oxidation of the reagent by nitric acid is avoided, and if the cold liquid, kept in a closed bottle for 1 or 2 days, retains the odor of sulphuretted hydrogen, all the arsenic will be found in the precipitate, and by decanting, filtering, and evaporating the liquid pure phosphoric acid will be obtained. In the absence of arsenic only phosphorous and nitric acids may remain as impurities, the former of which requires oxidation with nitric acid, while the latter is expelled by heating to 188° C., as stated above, and until a glass rod moistened with ammonia ceases to produce white fumes when held over the capsule. At a higher heat, notably between 210° and 213° C. (410° and 415° F.), pyrophosphoric acid would be produced.

Prof. Markoe (1875) proposed a process in which the oxidation of the phosphorus is effected through the intervention of iodine and bromine and at a low temperature. 2 troyounces of phosphorus and 12 troyounces of water are put into a flask or stone jar; 10 grains of iodine are added, and then 60 grains of bromine by drops; when the reaction has ceased, add 12 troyounces of nitric acid; set the vessel in cold water, and when in about 24 hours the solution has been effected evaporate the liquid until all the iodine, bromine, and nitric acid has been expelled. In this process some bromide and iodide of phosphorus is formed and decomposed by the water, with the formation of phosphoric, hydrobromic, and hydriodic acids, from the last two of which, reacting with the nitric acid present, bromine and iodine are again produced, which again act upon the phosphorus, etc. It is very important to follow the above directions strictly, since the incautious addition of bromine to phosphorus and nitric acid may cause a dangerous explosion. The solution is tested and finished in the manner described above.

Prof. W. T. Wenzell (1882) has again suggested a process, which was originally proposed by Bucholz, and was formerly much employed. When phosphorus is partly immersed in water in such a manner that the sticks are not in contact with one another, and the apparatus is arranged so that the air has access to the phosphorus, the latter will be gradually oxidized in the moist atmosphere to phosphorous acid, and this is subsequently oxidized by nitric acid. It is obvious that a considerable amount of the latter may be saved by utilizing atmospheric oxygen, but it is necessary to adopt the precautions indicated above, and thus prevent the exposed phosphorus from igniting. The mixture of phosphorous and phosphoric acids obtained by spontaneous oxidation was formerly known as *phosphatic acid*.

3. ACIDUM PHOSPHORICUM DILUTUM, U. S., Br.; Diluted Phosphoric Acid, *E.*; Acide phosphorique médicinale, *Fr.*; Verdünnte Phosphorsäure, *G.*

Mix Phosphoric Acid 20 parts with Distilled Water 80 parts.—*U. S.*

The British Pharmacopœia directs this acid to be prepared from phosphorus by oxidizing 413 grains of it by means of 6 fluidounces of nitric acid properly diluted, and with

the precautions explained above; the finished product measures 1 pint (Imperial). It is more than one-third stronger than that of the U. S. P.

Properties.—1. **GLACIAL PHOSPHORIC ACID.** The commercial acid is in colorless transparent, glass-like masses, which are slowly deliquescent in the air, and soluble in water and in alcohol; the solution has a strongly acid taste. It is metaphosphoric acid mixed with variable proportions of pyrophosphoric acid, according to the degree and duration of the heat used in preparing it; its aqueous solution yields gradually a bulky precipitate with tincture of ferric chloride. Chemically pure metaphosphoric acid is a soft gum-like mass, which melts at an elevated temperature, is volatilized at a red heat, and becomes solid and glass-like in the cold only through the presence of some sodium or other phosphates (Brescius, 1867). We found (1860) commercial glacial phosphoric acid to contain from 76.46 to 83.48 per cent. of phosphoric anhydride against the calculated quantity of 88.75, the impurities consisting of excess of water and of calcium and magnesium phosphates. Prescott obtained (1872) from the commercial acid an amount of soda corresponding to from .023 to .038 per cent. of sodium phosphate. Brescius found in a sample 15.3 per cent. of soda. These impurities render it unfit for the preparation of the medicinal phosphoric acid which was permitted by the Pharmacopœia of 1870. When dissolved in water it is gradually converted into orthophosphoric acid, the change being hastened by boiling; the solution best adapted for this purpose, according to Littleton Thompson (1874), is made of 1 part of the glacial acid and 2 parts of water, when boiling for about 15 minutes was found to be sufficient. The presence of a small quantity of nitric acid favors the change.

Several series of salts are known of both metaphosphoric acid and pyrophosphoric acid, all of which are converted into orthophosphates by boiling with diluted acids, by heating with water to 280° C. (536° F.), and by fusing them with an excess of alkali. The soluble metaphosphates have a neutral or slightly acid reaction: the normal pyrophosphates are faintly alkaline, and the acid pyrophosphates of a weak acid reaction.

The insoluble salts of both acids are mostly soluble in dilute acids. Ferrous, ferric, and mercurous pyrophosphates, and those of copper, zinc, lead, and silver, dissolve also in solution of sodium pyrophosphate.

2. **PHOSPHORIC ACID.**—The acid now recognized under this name is a colorless, inodorous acid liquid having the specific gravity 1.348, but the German Pharmacopœia recognizes as acidum phosphoricum an acid of the density 1.120, and of exactly double the strength of acidum phosphoricum dilutum, *U. S.* If evaporated at a temperature not exceeding 160° C. (320° F.), a syrupy liquid is obtained, which gradually on standing, more rapidly on the addition of a crystal of phosphoric acid, yields colorless, flattish, hexagonal prisms, melting at about 40° C. (104° F.), deliquescent in a damp atmosphere and completely soluble in alcohol and in water. The following table, by H. Schiff, indicates the strength of aqueous solutions in phosphoric acid and phosphoric anhydride: it agrees nearly with the results obtained by Watts:

Specific gravity.	Percentage		Specific gravity.	Percentage		Specific gravity.	Percentage	
	H ₃ PO ₄ .	P ₂ O ₅ .		H ₃ PO ₄ .	P ₂ O ₅ .		H ₃ PO ₄ .	P ₂ O ₅ .

The salts of orthophosphoric acid, with the exception of those of the alkalis, are

mostly insoluble in water; the insoluble ones dissolve in nitric acid, likewise in acetic acid, with the exception of the phosphates of lead, iron (ferric), uranium, and aluminium. The reaction of normal alkaline orthophosphates is strongly alkaline, of the monohydric salts slightly alkaline, and of the dihydric salts distinctly acid. The solution of an orthophosphate rendered alkaline by ammonia yields a white precipitate with a mixture of magnesium and ammonium salts. This precipitate is insoluble in ammonia, sparingly soluble in water, freely soluble in acids, and at a red heat is converted into magnesium pyrophosphate; this reaction is often used for the gravimetric estimation of phosphoric acid. (See MAGNESII SULPHAS.) For its volumetric estimation a solution of ferric chloride, lead acetate, or uranic acetate is employed, the precipitates by the three salts being soluble in nitric acid, but insoluble in acetic acid. The strength of medicinal phosphoric acid, which has been proved to be free from other acids and from salts, is conveniently ascertained by combining with lead, using an excess of the pure oxide, evaporating to dryness, and igniting, when the increase of weight indicates the amount of phosphoric anhydride. 100 parts H_3PO_4 yield 72.449 parts P_2O_5 ; therefore 5 Gm. of the 50 per cent. phosphoric acid, after treatment with 10 Gm. of pure oxide of lead in the manner stated, must yield a residue weighing 11.8112 Gm.

3. DILUTED PHOSPHORIC ACID corresponds in all respects to the preceding, except that it contains only 10 per cent. of H_3PO_4 and has the density 1.057. When 10 Gm. of this acid are treated with 5 Gm. of pure oxide of lead, as described above, the residue should weigh 5.7245 Gm. The British Pharmacopœia requires 355 grains of its acid to yield with 180 grains of oxide of lead a residue weighing 215.5 grains; 6 fluidrachms (*Br.*) of this acid correspond to 35.5 grains P_2O_5 or 49 grains H_3PO_4 .

Impurities.—Pure glacial phosphoric acid dissolves completely in distilled water, and this solution is not precipitated on standing for 2 days, after having been saturated with hydrosulphuric acid (arsenic, lead). When boiled for some time, and then supersaturated with ammonia, no precipitate is produced, with the exception of a slight turbidness (calcium, magnesium), and the further addition of ammonium sulphhydrate causes no change (iron and similar metals). With caustic potassa in excess ammonia is not evolved. If completely precipitated by acetate of lead, the filtrate, after the excess of lead has been removed by sulphuretted hydrogen, leaves, on evaporation, only a very minute residue (potassium, sodium). Medicinal phosphoric and diluted phosphoric acid are tested in the same manner as the preceding, except that for the detection of calcium and magnesium boiling is not required before supersaturating with ammonia. The presence of nitric acid is determined by the black or dark-brown color appearing on the addition of a crystal of ferrous sulphate, followed by the careful addition, without agitation, of concentrated sulphuric acid. In applying the following tests the stronger phosphoric acid should be diluted with 4 or 5 volumes of distilled water: Hydrochloric acid is detected by the curdy-white precipitate insoluble in nitric acid occurring with nitrate of silver; sulphuric acid, by a white precipitate with barium chloride; and phosphorous acid, by the speedy decoloration of a drop of solution of potassium permanganate or by the precipitate of calomel when warmed with solution of corrosive sublimate. Sulphuretted hydrogen should not produce either a white turbidity of sulphur (phosphorous acid), or, after standing, a colored turbidness or precipitate (arsenic, lead). Arsenic is most conveniently detected by Fleitmann's test (see page 28) after supersaturating the acid with potassa or soda. The German Pharmacopœia directs the evolution of hydrogen by means of sulphuric acid and zinc, and to proceed as described for the detection of arsenic in hydrochloric acid. (See page 65.)

Off. Prep.—Ammon. phosphas, Syrupus ferri phosphatis, *Br.*

Physiological Action and Medical Uses.—The views expressed by different writers in regard to the degree and mode of action of phosphoric acid are not easily harmonized. According to J. Ashburton Thompson, "the complete oxidation of the phosphorus is calculated to destroy its therapeutical properties entirely." Burness declares that "it is not astringent, but forms soluble compounds with albumen and fibrin," while Hoffman states that as a hæmostatic "it is better than other astringents." Burness further asserts that "if continued for some time it causes cough and expectoration, passive congestion, especially in the extremities, pain in the bones, a febrile state with profuse perspiration, followed by diarrhœa, depression of the mental powers, and pain in the generative organs;" and, in opposition to all of these, Dr. J. B. Andrews affirms that although it is a powerful stimulant of the brain and nervous system, "in no case does it disturb the digestion or prove an irritant to the stomach, even when its administration is prolonged" (*Amer. Jour. of Insanity*, Oct. 1869). According to Sundelin, it is a powerful

excitant of the genital organs; while Andrews agrees with Neligan that it exerts no direct influence upon the generative function.

According to Andrews, the sensations produced by a dose of from 40 drops to 3 drachms of the acid were those of moderate alcoholic stimulation. When a larger dose was taken there was a feeling of drowsiness and inertness that continued for some hours. It was employed by this physician in many cases of insane *melancholy* and of persons whose minds had been overtaxed and who had become nervous and timid, with a sense of weariness and inability to continue any occupation. But as its use was supplemented by "relaxation from business and labor" and "some suitable tonic," and, especially in some popular medicines, with iron, potassa, magnesia, and lime, the share of phosphoric acid in the patient's improvement is more than problematical. It has been used, on theoretical grounds, in the treatment of *dyspepsia*, with an excessive proportion of earthy phosphates in the urine; in *scrofulous caries* and in *exostoses* of the bones; to correct *night-sweats* in phthisis and other hectic diseases; in *hæmoptysis* and in *catarrhal affections* of the lungs and of the genito-urinary organs; in *jaundice* and in *diabetes*. In the last-named disease it has a remarkable power of diminishing thirst, and consequently of lessening the harassing secretion of urine. At the same time it affords an agreeable acidulous beverage. The dose of medicinal phosphoric acid is from 20 minims to a fluidrachm (Gm. 1.30–4.00), sufficiently diluted to be agreeable to the taste.

ACIDUM PICRICUM.—PICRIC ACID.

Acidum carbazoticum.—*Carbazotic or Nitrophenic acid, Trinitrophenol*, E.; *Acide picrique, carbazotique, nitro-anthique, etc.*; *Jaune-amer*, Fr.; *Pikrinsäure, Trinitrocarbolsäure, Welter'sches Bitter*, G.

Formula $C_6H_2(NO_2)_3OH$. Molecular weight 229.

Origin and Preparation.—A solution of this compound, as obtained from indigo, was recognized as a dyeing material by Woulfe (1771). Haussmann (1788) prepared picric acid from the same material as a bitter mass; Welter (1799) obtained it in crystals from silk, and subsequently its composition was investigated by Liebig, Dumas, and others. It may be obtained by the action of nitric acid upon salicin and its derivatives, phloridzin, indigo, aloes, benzoin, silk, and other substances, and is best prepared by dropping 1 part of carbolic acid into 3 parts of warm nitric acid, adding, after the violent reaction has ceased, 3 parts of fuming nitric acid, heating the mixture, and finally evaporating it, when, on cooling, the new compound will crystallize, and may be purified by washing with cold water and recrystallizing from boiling water or diluted alcohol; $C_6H_6O + 3HNO_3$ yields $C_6H_2(NO_2)_3O + 3H_2O$.

Properties.—Picric acid crystallizes in bright-yellow, inodorous needles or scales, which melt at $122.5^\circ C.$ ($252.5^\circ F.$), and when cautiously heated sublime without decomposition, forming yellow suffocating vapors which condense again to crystals; but on being rapidly and strongly heated in a test-tube picric acid is decomposed with detonation, while upon platinum-foil it burns with a sooty flame, without leaving any residue. It has an acid and extremely bitter taste, dissolves at $5^\circ C.$ ($41^\circ F.$) in 160 parts, at $15^\circ C.$ ($59^\circ F.$) in 86 parts, and at the boiling temperature in 25 parts of water, forming a bright-yellow solution, and is readily soluble in alcohol, ether, chloroform, benzol, and petroleum benzin. Its solutions stain the skin and other organic matter permanently yellow; hence its use in dyeing. The aqueous solution precipitates gelatin. It unites with bases, forming salts which are mostly yellow, crystallizable, have a bitter taste, and are explosive by percussion or when heated. The potassium picrate requires 260 parts of water of $15^\circ C.$ ($59^\circ F.$), but only 14 parts of boiling water, for solution.

Tests.—The above-described properties are sufficient for recognizing the acid. Its purity is shown by the complete solubility in the solvents mentioned before. On heating an aqueous solution of picric acid with chlorinated lime, very pungent and irritating vapors of the so-called *chloropicrin* are given off—a compound more properly known as *nitrochloroform* and *nitrotrichloromethane*, $C(NO_2)Cl_3$.

Pharmaceutical Uses.—A solution of 1 part of picric acid in 100 parts of water forms a convenient test for alkaloids, nearly all of which are precipitated from their diluted acidulated solutions, except aconitine, caffeine, cocaine, conine, hyoscyamine, morphine, and theobromine.

Picric acid is much employed for dyeing wool and silk yellow, also for staining wood.

Physiological Action and Uses.—When given continuously to rabbits it causes emaciation, diarrhoea, ecchymosis in the intestine, yellowness of the conjunctiva and of

the urine, and in large doses nausea, diarrhœa, flatulence, depression, and twitching of the cutaneous muscles. After death the red blood-disks are found dissolved in part, and in the white corpuscles the nuclei exhibit a lively molecular movement. The acid, and also its salts, given to man induce a yellowness of the conjunctiva, skin, and urine. This fact is of interest as illustrating the mode of production of jaundice in certain cases, as in yellow fever and acute yellow atrophy of the liver. It has been prescribed in doses of from one-sixth of a grain to 2 or 3 grains (Gm. 0.01–0.20) in alcoholic solution. Picrate of ammonium has been used in the treatment of *intermittent fever* and of *intestinal worms* in doses of about a quarter of a grain, and upon theoretical grounds, but fruitlessly. It has been applied with alleged advantage to *fissured nipples* in solutions containing 13 parts, and also 1 part in 1000 of distilled water. At present it does not appear to possess much therapeutical value. It has been used as a test for albumen (*Med. News*, xliii. 458).

ACIDUM SALICYLICUM.—SALICYLIC ACID.

Ortho-oxybenzoic acid, E.; *Acide salicylique*, Fr.; *Salicylsäure*, G.

Formula $\text{HC}_7\text{H}_5\text{O}_3 = \text{C}_6\text{H}_4.\text{OH}.\text{COOH}$. Molecular weight 138.

Origin and Formation.—It occurs in the free state in the flowers of *Spiræa Ulmaria*, and as methyl-salicylic ether in the leaves of *Gaultheria procumbens* and *Andromeda Leschenaultii*, and is formed from salicin, indigo, and some other organic matters by adding them to hydrate of potassium heated to fusion. It was discovered by Piria (1838) as a derivative of salicin; its presence in oil of wintergreen was proven by Procter (1848), and in several species of *viola* by Mandelin (1881).

Preparation.—It may be prepared from oil of wintergreen by heating it with strong solution of potassa as long as methylic alcohol is given off, and decomposing the resulting potassium salicylate by hydrochloric acid. But it is at present extensively prepared, according to Kolbe (1874), from carbolic acid. As the first step, dry sodium carbolate is prepared, which is introduced into a retort; dry carbonic acid gas is passed through it while heat is applied, gradually increased from 100° C. (212° F.) to 220° C. (428° F.), and not over 250° C. (464° F.). By this operation carbonic anhydride is made to enter into the molecule of phenol, producing sodium salicylate and sodium carbonate, while one-half of the carbolic acid distils over; $2(\text{NaC}_6\text{H}_5\text{O}) + \text{CO}_2$ yields $\text{Na}_2\text{C}_7\text{H}_4\text{O}_3 + \text{C}_6\text{H}_6\text{O}$. The residue in the retort is now dissolved in boiling water, filtered if necessary, and decomposed by hydrochloric acid, when, on cooling, impure salicylic acid, having a brown or reddish-brown color, is precipitated in the form of a crystalline powder; this reaction occurs as follows: $\text{Na}_2\text{C}_7\text{H}_4\text{O}_3 + 2\text{HCl} = 2\text{NaCl} + \text{C}_7\text{H}_6\text{O}_3$ (salicylic acid), sodium chloride remaining in solution. The impure acid thus obtained is further purified by dissolving it in boiling water or weak alcohol, treating the solution with animal charcoal, and crystallizing the filtrate after the addition of a little hydrochloric acid. A. Rautert recommends (1875) the purification of it by distillation with steam previously heated to 170° C. (338° F.), by which some black resin is left as a residue; by recrystallization from boiling water a little carbolic acid is removed. Contact with iron or with materials containing iron is to be avoided, since a reddish color is thereby imparted. According to Squibb (1877), it is best purified by subliming it with the aid of steam-heat.

Properties.—Thus obtained, salicylic acid is in small acicular crystals, white, inodorous, of a sweetish, acidulous, somewhat acrid taste, and of the spec. grav. 1.45. The commercial article frequently has a yellowish or brownish tinge and a slight odor. It fuses at 155.5° C. (312° F.), and if carefully heated sublimes unaltered, and without boiling, at about 200° C. (392° F.). When rapidly heated to between 220° and 230° C. (428° and 446° F.), it is decomposed into carbonic dioxide and phenol; $\text{C}_7\text{H}_6\text{O}_3$ yields $\text{CO}_2 + \text{C}_6\text{H}_6\text{O}$. According to Bourgoïn (1879), 1000 parts of distilled water dissolve

At 0°	5°	10°	15°	20°	30°	50°	60°	70°	80°	90°	100° C.
in 1.50	1.65	1.90	2.25	2.70	3.90	8.00	12.25	19.90	32.55	51.80	79.25 parts salicylic acid.

The hot solution, when slowly cooled, yields long, slender needles. The solubility in water is considerably increased by the addition of phosphates, citrates, and acetates of the alkalies and of borax, the solution made with the latter gradually acquiring a bitter taste. It dissolves freely at ordinary temperatures in wood spirit, in 2 parts of absolute

FIG. 8.

Crystal of Salicylic Acid.

and 2.4 parts of 90 per cent. alcohol, in 3.5 parts of amylie alcohol, in 2 parts of ether, in 80 parts of chloroform, in 80 parts of benzol, and in 60 parts of fixed oils. Its solution in 5 parts of boiling oil of turpentine congeals on cooling. C. Becker (1875) observed that 1 part of salicylic acid and 2 parts of olive oil, heated together, form a homogeneous mixture. The alcoholic solution evaporated spontaneously yields the acid in large oblique quadrangular prisms. The aqueous or alcoholic solution acquires a deep violet color with ferric chloride, provided alkalies, alkaline salts, and most acids are absent. The aqueous solution yields with bromine-water a crystalline precipitate sparingly soluble in water, and when boiled with Millon's reagent of mercuric nitrate gives a red color. A blood-red color, changing to brown and black, is produced by adding an excess of sulphuric acid to a mixture of salicylic acid and sugar, and applying a gentle heat. Sulphate of copper produces an emerald-green color in very dilute solutions of normal salicylates or salicylic acid. Potassium chlorate and hydrochloric acid convert it, like phenol, quinone, and allied compounds, into *chloranil* or tetrachloroquinone, $C_6Cl_4O_2$, which forms yellow crystals soluble in ammonia with a deep-red color. Salicylic acid effervesces with carbonates, behaving as a monobasic acid; but under certain circumstances a second hydrogen atom may be replaced by metals, yielding Piria's neutral salicylates (1855), which are decomposed by carbonic acid. Combined with alkalies, the solution of salicylic acid turns brown in contact with the air. On dry distillation the salicylates are decomposed, yielding carbonic dioxide and phenol.

Impurities.—According to J. Williams (1878), salicylic acid prepared by Kolbe's process is contaminated with another acid, which he provisionally named *cresyl-salicylic acid*, and which remains in the mother-liquor on neutralizing a solution in hot water with carbonate of calcium; if the precipitated salicylate of calcium be purified by recrystallization from boiling water and afterward decomposed by hydrochloric acid, pure salicylic acid is obtained. It should be absolutely free from the odor of phenol, the presence of which lowers its melting-point, and its aqueous solution, to which a little nitric acid has been added, should not be precipitated by chloride of barium (sulphuric acid) or by nitrate of silver (hydrochloric acid). Heated upon platinum foil, salicylic acid should evaporate without leaving any residue (mineral impurities). It should dissolve in cold concentrated sulphuric acid without imparting any or only a faint yellow-color (organic impurities). Kolbe (1876) has given the following practical test: It should be completely soluble in absolute alcohol, and the solution, if allowed to evaporate spontaneously and without contact with iron, should yield a white residue of aggregated crystals, the points of which are colorless and transparent. In the presence of iron the ends will be reddish or purplish, and with organic coloring matter will appear yellowish or brown.

Two other oxybenzoic acids are known, which melt at 200° and 210° C. (392° and 410° F.) and do not give a violet-red color with ferric chloride. The para-acid is more freely soluble than the others, and is obtained in Kolbe's process for salicylic acid by using potassium instead of sodium phenate and increasing the heat to above 150° C. (302° F.).

Pharmaceutical Uses.—ACIDUM BOROSALICYLICUM, Borosalicylic acid. Dissolve 1 part of boric acid in 5 parts of boiling water, and 2 parts of salicylic acid in 10 parts of alcohol; mix the solutions, and evaporate slowly by means of a water-bath (Hager). It is a white crystalline powder or small needles, soluble in 200 parts of cold water, 40 parts of hot water, and 10 parts of alcohol, and has a persistently bitter taste. It possesses antiseptic properties.

SALICYLIC COLLODION. Dissolve salicylic acid 6 parts and extract of cannabis 1 part in collodion 48 parts (Glezon). It has been recommended for the removal of corns, and is applied for 4 or 5 consecutive nights and mornings, followed on the next day by a warm bath.

Salicylic acid is used for the preparation of salicylated cotton, of sodium salicylate, *U. S.*, and other salts.

Salts of Salicylic Acid.—SALICYLATE OF SODIUM is prepared by adding salicylic acid to a cold solution of pure soda containing 10 per cent. of caustic soda as long as it is dissolved, filtering, and evaporating to dryness. Or 10 parts of salicylic acid are mixed with water into a thin paste, and to this mixture 10 parts of pure crystallized carbonate or 6 parts of pure bicarbonate of sodium are added; after the evolution of carbonic acid gas has ceased the solution is perfectly neutralized with a little caustic soda and evaporated to dryness. The salt forms a white powder, has a sweet afterward acid taste, dissolves in rather less than its own weight of cold water, and is soluble in alcohol, but sparingly soluble in absolute alcohol. Prepared by the second process, it has the com-

position $\text{NaHC}_7\text{H}_4\text{O}_3$; but if made by the first process Hager (1876) found it to yield 33 per cent. of residue when incinerated; its composition will therefore be nearly $\text{Na}_2\text{C}_7\text{H}_4\text{O}_3$.

SALICYLATE OF AMMONIUM is prepared, like the preceding salt, by neutralizing salicylic acid with ammonia or carbonate of ammonium, and evaporating, when the monobasic salt crystallizes in scales or needles; but on rendering the concentrated liquid alkaline with ammonia the bibasic salt is obtained. Both have a sweet taste and are readily soluble in water.

Medical History.—As long ago as 1855, Bertagnini is said to have studied the action of salicylic acid upon himself; and in 1874, Kolbe, besides producing the acid synthetically, illustrated its anti-putrid and anti-fermentative actions.

Physiological Action.—*On Vegetables, etc.*: Plants watered with a solution of this acid speedily die. It prevents various reactions in organic products; *e. g.* hinders the development of prussic acid in a mixture of amygdalin and almond emulsion, of the acrid principle of mustard on the addition of water, the souring of beer, milk, etc. It prevents the putrefactive fermentation of urine, and arrests this process after it has commenced. When given internally or injected into the bladder as an acid or in saline combination, it prevents the fermentation of urine in that organ, and restores its acid reaction when it is lost. It has no strictly deodorizing action, and therefore is not available in a great many cases in which foul smells, and not their cause, must be attacked. It, however, deodorizes ammoniacal urine, probably by a chemical action.

On Animals: About a grain of salicylate of sodium introduced under the skin of a frog renders the animal languid, and then occasions complete motor paralysis and arrest of the heart. Guinea-pigs after a dose of from 60 to 70 grains grow rapidly weak, lie on the belly, and drag their limbs, which are moved spasmodically; then respiration grows shallower until it ceases. From such experiments Rochefontaine concluded that the acid (1) impairs general and reflex sensibility by its action on the brain and spinal marrow; (2) muscular contractility and excito-motility are suspended later; (3) respiratory movements are arrested; and (4) the heart ceases to beat. The experiments of Laborde, furnishing the same general results, led him also to conclude that the salt acts upon the nerve-centres and not upon the nerves. But he also found that common sensibility and the perception of pain were both blunted, as well as muscular power, and, indeed, so conspicuously that he concluded the virtue of the medicine as an anti-rheumatic remedy to be mainly, if not exclusively, in its analgesic or anodyne power. Other experimenters found that the acid does not reduce the pulse-rate or the temperature in healthy animals, nor modify their sensibility. More definite conclusions were deduced by Lahalle from his experiments upon dogs (*Thèse de Nancy*, 1878). Their chief points are contained in the following propositions: 1. Moderate doses of salicylate of sodium occasion nausea, salivation, vomiting, and diarrhoea. Larger doses may cause bloody stools and tenesmus and vomit with streaks of blood. 2. The senses of sight and hearing appear to be somewhat dull. 3. The central nervous system is affected only by large doses, which abolish together sensibility, motility, and reflex excitability, and tetanic spasms precede death. 4. The pulse remains either quite undisturbed or is slightly lowered; exceptionally it becomes more frequent. 5. The primary and chief action of the salt is upon the respiration, which is quickened even by small doses. 6. It not only does not lower the temperature, but raises it by several tenths of a degree ($^{\circ}\text{C}$.) unless fever is present, in which case the temperature falls about 1°C . and the pulse becomes less frequent. 7. Sodium salicylate is not a diuretic; on the contrary, in excessive doses it renders the urine albuminous and lessens its quantity. It is excreted, however, by the kidneys chiefly (as Feser and Friedeberg had already shown). It increases the flow of saliva and bile. (This statement agrees with that of Rutherford, who says that sodium salicylate "is a very powerful hepatic stimulant in the dog.") It is also found in the biliary secretion. 8. After death the stomach, the duodenum, and more generally the whole intestine, are deeply congested, sometimes with sub-mucous hæmorrhage and desquamation of the epithelium; the liver and kidneys are also congested, as well as the meninges, which present spots of extravasation; the brain and spinal cord appear to be congested; the lungs are unaffected and the blood seems unchanged. As complementary to these conclusions, and confirmatory of them, it may be stated that those of Blanchier (1879) include the following: Sodium salicylate displays decided physiological effects only in large doses, which first stimulate and then paralyze the central nervous system, exciting through it gastrointestinal phenomena and fatal disorder of the respiration; it does not act directly upon the nerves, but does so upon the nervous ganglia and the glands and upon the muscular

fibre, inhibiting their respective functions. In this connection it may be added that Prudden (*Amer. Journ. of Med. Sci.*, Jan. 1882, p. 69) concluded from his experiments that salicylic acid restrains the emigration, and in strong solutions is inimical to the life, and in dilute solutions to the activity, of the white blood-cells.

On Man: Among the most usual effects of salicylate of sodium in full medicinal doses are subjective auditory phenomena consisting of buzzing, humming, whistling, rushing, and knocking noises, accompanied with more or less deafness. They are seldom absent when the quantity of the medicine taken in 24 hours exceeds 150 grains. Occasionally vision is disturbed, and objects appear to oscillate or to revolve. Gatti reports the case of a patient who while using this medicine remained blind for about 10 hours. Headache is not unusual, and may be attended with slight excitement or with dulness and an uncertain gait. When fever exists delirium is readily induced by the medicine, especially in nervous patients. It is apt to be accompanied with phantasms and violence, as in delirium tremens. Difficulty of breathing and palpitation of the heart are ordinary effects of the medicine, and the former symptom has been repeatedly observed in phthisical patients. Pulmonary hæmorrhage has been caused by it even in healthy persons (Wattelet). Hence it should be a rule never to prescribe the medicine in cases involving cardiac or pulmonary disease, and equally so, whenever it is used, to watch its influence upon the circulation and respiration. Apart from febrile states, the pulse and the temperature are not reduced by it, according to Godl, Riegel, and others; and Lürmann having given salicylic acid to a person affected with nodosity of the joints saw the pulse-rate rise to 160 and the temperature to 105.8° F. Analogous effects were produced in healthy persons under the direction of G. Sée, who, like other observers, noted no change in the arterial tension, the pulse-rate, or the temperature, unless fever already existed. Marigliano's experiments confirm these observations (*Practitioner*, xxx, 52). The large elimination of salicylic acid and its compounds by the kidneys explains their various effects upon these organs. If they are sound, and if the dose is not excessive or too long continued, the urine either remains normal in quantity or is more or less increased; but if the kidneys are diseased or the dose of the medicine is excessive, the secretion diminishes, vesical irritation occurs, and albumen, and even blood, may be found in the urine (*Centralblatt f. d. g. Therapie*, i, 527; *Med. Record*, xxv, 12). Sodium salicylate, but still more the uncombined acid, acts as an irritant upon mucous membranes. It occasions a sense of rawness in the fauces, and even vesicles and ulcers there, nausea, vomiting, and gastric distress, and sometimes diarrhœa. Like many other irritants, salicylic acid and its compounds occasionally produce an eruption on the skin, usually in the form of urticaria. But it is also stated to have occasioned numerous and large petechiæ and vibices. Besides these superficial lesions, it has happened that gangrene has been produced by this medicine, as in cases seen by Wattelet, Potain, and Gubler in France; while in England it is recorded that in a case of acute articular rheumatism it produced ecchymosis, gangrene, disorganization of the eyes, and the death of the patient (*Times and Gaz.*, Sept. 1879, p. 339). During the use of salicylic acid and its compounds the urine gives a violet color on the addition of solution of perchloride of iron. Its passage through the system is very rapid, for in a case of extrophy of the bladder its presence in the urine was demonstrated in about 8 minutes after 75 grains of salicylate of sodium had been taken. But its excretion does not cease for several days after the medicine has been suspended. It appears, however, to undergo a change before elimination, since the urine containing it does not check the fermentation of yeast. According to Byasson, salicylic acid appears in the urine "partly unchanged." It increases (?) the elimination of uric acid and nitrogenous compounds. In numerous cases the urine has apparently responded to the copper test for grape-sugar, but the precipitate was found not to be cupreous. Besides its elimination with the urine, it is also excreted in a small proportion with the sweat and with the serum of blisters; it is generally thought not to be discoverable in the saliva, but one observer (Musy) found it there.

The occasional toxic effects produced by salicylic acid and its compounds are partly local and partly general. The former consist mainly of the irritations already referred to, but they are by no means usual, and often excessive doses are employed without injury. Thus a patient affected with rheumatism took 6 drachms of salicylate of sodium in the course of 22 hours; he suffered no pain in the stomach, but, on the contrary, his appetite was improved (Ewald). Feltz reports the case of a man who took more than 6 ounces of the salt in 1 month. In the last 17 days the dose was 120 grains three times a day. The symptoms were chiefly vomiting and headache, preceded by congestion of the neck, face, and head. The pupils were contracted. The symptoms continued for 17 days

after the last dose had been taken, and the acid could be detected in the urine for 16 days. But in other cases the effects were fitted to inspire anxiety. Ewald reports that a woman became affected with alarming symptoms after using the acid or its sodium salt. After a drachm of the latter there was repeatedly observed delirium like that from alcohol, but more frequently extreme jactitation, and even maniacal fury; also roaring in the ears, disorders of vision, and loss of muscular power in the limbs. The last symptom sometimes reaches the degree of complete resolution, and the gastric disturbance may resemble that produced by a corrosive poison. In children it occurs most frequently, as well as the prostration of the nervous system. In a case of acute articular rheumatism a rapid cure appeared about to take place, when, besides buzzing in the ears and profuse sweats, extreme prostration came on, and the patient died suddenly on sitting up to eat (Empis). Jaccoud soon afterward reported three cases of sudden death in young rheumatic patients treated by this medicine in doses not exceeding 150 grains a day; and Goodhart one in which death followed the use of four doses of 15 grains each, given at intervals of 3 hours (*Times and Gaz.*, Jan. 1880, p. 105). Lahalle (*Thesis* cited) ventures to say that although the avowed number of fatal cases in France is considerable, yet probably others have occurred that have not been published. In the cases now referred to the phenomena seem to have been due to a derangement of the nervous system, but there have been others in which the heart was affected or the lungs; in the latter the symptoms were those of asphyxia. In another case, a girl of 15 took by mistake 7 drachms of salicylate of sodium within a few hours; besides the symptoms already mentioned she had dilated pupils, impaired vision, and strabismus, and became melancholic. Red spots appeared transiently on the skin; there was vomiting, but no diarrhœa; the urine contained albumen (Peterson). It sometimes contains blood or casts. Abelin states that acute nephritis may occur during the use of the medicine. It follows from the above that salicylic acid, and in a less degree its salts, should not be given in large doses to persons having a weak heart or who are otherwise greatly debilitated, or, at least, not without counteracting their toxic tendencies with nutrients and diffusible stimulants.

Medical Uses.—*Acute Articular Rheumatism.* If salicylic acid and its compounds are curative of any disease, it is this. That it reduces the pulse-rate, and in a much greater degree the temperature (from 103° F. to 98° F.), the latter in nearly all cases, there is no doubt. Whether it removes the disease as well as, or better than, some other remedies is not quite so certain. For acute articular rheumatism is a general disease, in which not only the joints, but several internal organs, and especially the heart, are apt to be involved. Now, it is on all hands admitted that salicylic acid and its compounds neither exert any preventive influence on these complications nor prevent relapses; and some even go so far as to maintain that their development or occurrence is favored by these medicines. This opinion is probably due in part to the rapid relief obtained in many cases from pain and fever and the imprudent exposure which is apt to follow. It is very certain that when complications do occur the medicines in question exert no control over them. Not only so, but heart affections may arise while the patient is under their fullest influence. It is therefore altogether probable that they have no anti-rheumatic virtues, and that they relieve inflammatory rheumatism merely by repressing two of its symptoms, very much as quinia, and aconite, and veratrum, and opium may do. In a series of over one hundred cases of rheumatism the average time during which the acid was administered was a little over 6 days, the extremes being 1 and 31 days. The average quantity of salicylic acid taken by each patient was about 400 grains. This result does not bear out the claim of the medicine to be a specific remedy for the disease in question. Moreover, it is certain that the anti-febrile influence of the medicine is not specific, for in certain cases of hyperpyrexia occurring in rheumatism it not only failed to reduce the temperature, but during its use the temperature rose from 101° to 107°. It would be unfair, in presenting a summary of this subject, to withhold the positive declarations of some of the most competent advocates of the medicine. Dr. Broadbent says: "I have yet to see the case of genuine acute rheumatism without complication in which the pain is not entirely gone and the temperature normal after six consecutive doses of 20 grains at intervals of an hour on 2 successive days." Mr. Sharkey remarks: "One must, I think, allow that its discovery as a cure for acute rheumatism is a triumph of empirical therapeutics which has probably had but few parallels in the history of medicine." Dr. Jacob gives, as a result of its use in 150 cases, the recovery of 103 within three days. More or less analogous results have been obtained in Germany by Traube, Stricker, Bälz, Lebert, and others, and, according to Dr. Ackland, out of nearly 425 cases only 21 deaths occurred. In France, Sée declares that "we may promise with almost certainty the cure

of febrile or apyretic acute rheumatism in from 2 to 4 days." Like other physicians, Blachez (1878) met with cases in which, under this medicine, the pains ceased "in from 36 to 48 hours." But he cautions against suspending its administration when the pains subside, and insists that relapses are common, although not severe. On the other hand, Guéneau de Mussy expresses a general dissent from these conclusions; and that eminent clinician, Jaccoud, while admitting that in febrile articular rheumatism, unaccompanied by any complication, it produces a cure more rapidly than any other medicine, denies that a uniform duration can be assigned to the treatment and that it tends at all to prevent or modify complications; and he holds that when these exist the medicine ceases to influence the rheumatic element of the attack. So, too, Dr. V. Y. Bowditch (1879) concluded from a series of records that the medicine is not a specific, yet that in acute cases, if used at the outset of the disease, pushed vigorously, and not abruptly suspended, "the most satisfactory results may be obtained." In 1879 and 1880, Drs. Andrew Clark and R. Southey fully corroborated the judgment of Jaccoud, the latter by an analysis of 51 cases (*St. Bart's Hosp. Rep.*, xv. 6). Findlay and Lucas, by a like study of 158 typical cases, in 60 of which the salicylous treatment was used, in 60 the alkaline, and in 38 a combination of alkalies and quinine, found that although the duration of the primary attack was rendered shorter by the first-named than by the other methods, yet it was attended with far more cardiac complications, relapses three times as frequently, and a more usual return of pain without pyrexia (*Lancet*, Sept. 20, 1879). Dr. Greenhow concludes, from a careful analysis of 50 recorded cases, that although the pain and distress of the patient are undoubtedly assuaged, for a time, by the salicylate of sodium, the duration of his illness is not shortened, neither is his recovery as rapid as under other modes of treatment. He moreover calls attention to the marked weakening of the first sound of the heart observed in so many cases, and suggests its immediate danger, as well as its remoter significance, as showing a degenerative influence on the structure of that organ (*Clin. Soc. Trans.*, xiii. 346). With clinical results so ample and positive on record (consult, further, "Summary" in *Boston Med. and Surg. J.*, April, 1882, p. 315; *Ephemeris*, i. 56) one is obliged to regret the errors of statements like those first quoted, and of such as these, that "by the brevity of the febrile condition the chances of the occurrence of cardiac complications are immensely diminished" (Moore), or that the medicine "immensely lessens the chances of heart disease or other complication" (Paul). As we have seen, the heart-complications form a special danger of the salicylous method of treatment. On the whole, it may be concluded that this method is anti-pyretic rather than anti-rheumatic. That in certain cases it should have appeared to be "prompt and decisive," or to have "acted like a charm," or to be "the only radical remedy for acute rheumatism," leaves out of view entirely the natural history of the disease, which in thousands of cases runs its course to cure within a week without any specific treatment. It also overlooks the well-known clinical fact that in one form the disease runs a steady course toward cure, and in another is broken up into a succession of remissions and relapses. The observations of Marrot throw some light on the nature of the influence exerted by the acid upon the blood and upon nutrition in this disease, and on their modification by the salicylate of sodium. Under its administration the excretion of urea and uric acid, which is so excessive in articular rheumatism, immediately declined, and the proportion of water was greatly augmented. One can hardly doubt that the sodium base of the medicine had a share in this result. The treatment by salicylic acid may be compared to that by opium, which was once in vogue, and which was vaunted to control the pain and fever of rheumatism, but, as was soon discovered, at the expense of the heart's integrity. A case of rheumatic tetanus is alleged to have been cured by salicylic acid. It is useless in *chronic rheumatism*. According to Abadie, salicylate of sodium greatly excels all other medicines in the rapidity of the cure of rheumatic *irido-choroiditis sclerotitis*. He recommends the dose of 15 grains four times a day (*Bull. de therap.*, xxvii. 385).

In *gout* the salicylates are said by Sée to display even more wonderful powers than in rheumatism, and to promptly arrest even the most painful paroxysms, as well as to prevent relapse and promote the removal of tophaceous deposits. Apparently, other physicians—Murchison, for example—have been less fortunate, for their results prove nothing in its favor.

If we cannot say that authors are unanimous in asserting the uselessness of salicylic acid in *intermittent fever*, we can at least declare that there is no proof of its utility, either by authority or by demonstration. In this case is presented an apt illustration of the error of deducing the therapeutical uses of a medicine from its apparent physiological action: for this acid and its compounds, whose physiological operation seems so closely to resemble that

of quinia, is powerless to cure the disease for which quinia is a specific remedy. Salicylate of quinia has been recommended as an anti-periodic medicine, and doubtless it is such as far as it contains quinia. In *scarlatina* and *variola* salicylic acid neither mitigates the disease nor tends to prevent its complications or sequelæ. As to *typhoid fever*, in which a full trial of the medicine has been made, the general result appears to be that it does not improve the typhoid state, nor reduce the splenic swelling, nor diminish the stools nor alter their qualities, nor lessen the customary debility and emaciation, nor improve the patient's feelings, nor shorten the attack, nor lessen the mortality of the disease. On the other hand, it is charged with causing hæmorrhage from the bowels. Reporters are not agreed even as to its influence upon the pulse and temperature; and some among them charge that it excites or exaggerates delirium, and produces nausea, prostration, albuminuria, and even suppression of urine (Sée; Murchison). These conclusions have been substantially confirmed by Filatow and by Weiss (1880), and no doubt remains of the inefficacy of this medicine, as of all others, in controlling typhoid fever. In *intermittent fever*, like many other agents, it may, as already stated, prevent or mitigate a paroxysm, but it has no influence on the disease. The medicine has been used in *relapsing fever*, with the alleged effect of lessening the duration and severity of the relapse (Riess, 1880); but as in one case the patient died with cerebral symptoms, a very rare occurrence in the disease, the share of the medicine in the catastrophe is open to suspicion. Dr. Bowyer claims that about 3 grains of salicylic acid every 6 hours aborts the eruption of *small-pox*! (*Practitioner*, xxvi. 456); another, that it is peculiarly efficacious, topically and internally, in *erysipelas* (*Amer. Jour. of Med. Sci.*, Jan. 1882, p. 255); and a third, that it is a prophylactic against *yellow fever*!

In *acute inflammations* the evidence respecting the medicine in question is very contradictory: for while, on the one hand, they are affirmed to be "wholly uninfluenced by it," that it does "not in the least degree prevent the supervention of fresh inflammation," and that, "while it reduces the temperature, it does not in the least modify the local processes," it is alleged, on the other hand, to be the "surest antiphlogistic." It is true that the latter judgment is qualified by the statement that it even "excels quinia;" which is quite conceivable, since it is now well settled that there is no constant relation between the reduction of the pulse in febrile affections and the cure of the disease which renders the pulse frequent. In regard to *diphtheria*, while one reports that in thirty-one cases it was "uniformly curative," and another that it "modifies favorably the exudation," and a third that it also "arrests the fever," a fourth (Abelin) "derived none of the advantages from its use which various physicians ascribe to it, and found that, except in reducing the temperature and the pulse-rate, its results were entirely negative, or else that it irritated the throat, and occasioned diarrhœa, albuminuria, or congestion of the lungs;" and Sée could discern no appreciable influence exerted by it on the disease. In a word, there is no ground whatever for believing in its efficacy. Even in the case of *aphthæ*, which some declare that it causes to heal rapidly, and of *thrush*, for which it has been vaunted as a specific, others allege that it is neither better nor worse than chlorate of potassium or than the alkaline solutions in general. Enemas containing 1 part of the acid to 300 parts of water, with a little alcohol to perfect solution, are said to lessen the frequency, correct the fetor, and improve the quality of the stools in *dyentery*. Ridder (1879) and Tlyn (1880) have reported the expulsion of *tenie* by salicylic acid. A purgative dose of castor oil was given, the patient kept on low diet for 24 hours, and a second dose of oil administered, followed by one of 12 grains of the acid, which was repeated hourly until 60 grains had been taken. Finally, half an hour later another half ounce of castor oil was given. The method is not recommended by its simplicity or its pleasantness. Experience has not determined its value. The medicine has been used in the hectic fever of *phthisis*, because it is capable of reducing the temperature, without regard to the serious injury it causes by deranging the digestion and its absolute nullity as a palliative of any symptom peculiar to pulmonary consumption. Very probably it may be profitable in correcting the fetor of the breath in certain cases of this disease; for it does so in *fetid bronchitis*, and even in *gangrene of the lung*, when administered by the stomach, and still better when inhaled from an atomized solution. Sachse recommends a solution of 2 parts of borax, 2½ parts of salicylic acid, and 100 or 150 parts of hot water for an inhalation in ulcerating phthisis. It is scarcely necessary to say that as a stimulant and deodorizing agent this mixture, if useful at all, is not so through the salicylic acid only which it contains. V. Toeplitz has vaunted the application of this acid to the larynx in *whooping cough*. Various stimulants and irritants have been used for the same purpose, including nitric acid, nitrate of silver, ammonia, etc., but have obtained little permanent credit. It has been found

efficient in preventing the development of acute *coryza* when given in doses of from 20 to 40 grains, and also in mitigating the symptoms of *hay-fever*. It has been thought to moderate the pain of *lumbago*. In *neuralgia* of a periodical type, and not amenable to quinia, it is said to have been very efficient in doses of from 20 to 40 grains, given every hour for 3 or 4 hours. Abbott (1879) has reported several cases of *sciatica* and of trifacial *neuralgia* in which its effects were prompt and permanent, and Labbé still others (1881), but he was of opinion that the medicine is only useful in cases of rheumatic neuralgia. Others regard its effects as very uncertain, and large doses of sodium salicylate as unsafe (Dujardin-Beaumetz). One or two cases of *chorea* of rheumatic origin appear to have been cured by this medicine. Schaetzke in 1879 published three cases of the rapid cure of *diabetes* by salicylic acid, given in doses of from 15 to 30 grains three times a day, and Sawyer (1881) three others with nearly as favorable an issue, in which sodium salicylate was associated with laudanum. Some years ago (1878) Barclay claimed that the value of salicylic acid in acute *gout* occurring in a previously healthy person was second only to that of colchicum. He does not, however, claim for it that prompt and decided action which it so often manifests in rheumatism, but he insists that in both diseases its use should be gradually, and not abruptly, discontinued. We have not met with any evidence that confirms the estimate of this physician.

As a topical remedy, salicylic acid has been employed in a powder mixed with silicate of magnesia (1 : 10), with which the skin is dusted to prevent *night-sweats*; and a powder made with 1 part of the acid to 6 or 8 of burned alum has been found efficient in correcting fetid sweating of the feet, when freely applied several times a day to the part, previously washed with soapsuds and wiped very dry. It is said that in the Russian and Italian armies a powder is used to prevent sweating and chafing of the feet, which is composed of salicylic acid 3 parts, starch 10 parts, and powdered tale 87 parts. An alcoholic solution of this acid (1 : 16) is recommended for removing the scales of *psoriasis*, for the treatment of *chloasma* and *freckles*, and as an anti-pruritic remedy. A solution of 1 part of the acid in 6 of glycerin has been found an efficient application to ulcerating *lupus*. Plasters containing salicylic acid have been used with great advantage to soften and remove various forms of *epidermal* thickening, including *corns*, *warts*, etc. The plaster especially recommended is composed of the acid incorporated with gutta-percha. Collodion has also been used as an excipient for the acid. An ointment recommended by Hager as an innocent cure for scalled head (*farus*) and an exterminator and preventative of lice is made by reducing salicylic acid 10.0 Gm. and borax 3.3 to a fine powder, adding yellow wax 50.0 and lard 250 Gm., previously melted together and colored with alkanet, balsam of Peru 10 Gm., oil of bergamot 50 drops, oil of star-anise 20 drops, and rose-water 30.0, and stirring until the ointment solidifies. *Eczema* and *intertrigo* may be cured by a 4 per cent. ointment of this acid. A lotion made with 1 grain of the acid to an ounce of water has removed the eruption and ulcers that sometimes are produced by *bromide of potassium*. Three cases of *urticaria* are recorded which were cured by about 20 grains of salicylate of sodium three times a day. The following mixture has been recommended in *ozæna*: Borax ʒiij; salicylic acid ʒij; glycerin ʒiiss; water to ʒiij. 1 or 2 drachms of this mixture to half a pint of water may be used as a nasal douche and as a gargle. As an external application it has also been a good deal used in dressing *wounds* and *ulcers*, and especially such as tend to *gangrene*. Sometimes the acid is applied as a fine powder, sometimes in a 1 per cent. solution. Indeed, a claim has been made that it is a perfect substitute for carbolic acid, over which it has the advantage of being inodorous, unirritating, and, when absorbed, not poisonous. It is, however, very irritating unless in a weak solution. Its somewhat styptic qualities have caused it to be used topically in *uterine catarrh*, *leucorrhœa*, and *chronic dysentery*, and even to arrest slight *hemorrhages*. A salicylate of iron has been employed for like purposes. 1 part of the powdered acid mixed with 5 parts of starch is said to correct *fætor* of the axillæ, feet, etc. It has been applied with alleged advantage to soft *chancre*s and to remove *corns* and *warts*. For the latter purpose it may be mixed with collodion. Salicylate of lime has been particularly recommended for *chancre*s and syphilitic sores (*Am. Jour. Med. Sci.*, July, 1880, p. 286). An ointment made with vaseline, and containing from 2 to 4 per cent. of salicylic acid, is recommended by Lassar as the best of all applications in *eczema*. If this ointment is found to be too soft it can be stiffened with oxide of zinc (*Centrallbl. f. d. ges. Ther.*, i, 389). Given by the mouth or rectum, it tends to diminish *fætor* of the stools in diarrhœa and dysentery. The addition of salicylic acid to vegetable infusions, solutions of bromide of potassium, quinia, atropia, morphia, etc. prevents the formation in them of fungous growths. Dr. J. G. Richardson recommends for hypodermic injection the following solution of morphia: R. Morphiæ

acet. vel sulph. gr. xvi; acid. acetic (No. 8) gtt ij; acid. salicylic. gr. iss; aquæ destillat. f ʒj. If, on standing in a conical glass, any sediment is observed, the clear liquid should be decanted.

Administration.—It is probable that salicin, salicylic acid, and salicylate of sodium are equally active physiologically. Salicin, although not very soluble, may be given in water in the dose of from 10 to 40 grains (Gm. 0.60–2.60), and salicylic acid in wafers and in similar doses. It is better to give the smaller dose and repeat it frequently than to administer a full dose at once. These substances may also be administered in powdered liquorice extract. Salicylate of sodium is now generally preferred to other forms of salicylic acid, on account of its solubility, but its alkaline base is probably not immaterial to the result. Not less than 60 or 70 grains (Gm. 4.00–4.60) should be given in divided doses at half-hour intervals, or 20 grains may be administered every 2 hours until six doses are taken, and on each of the two following days every 4 hours. If it disagrees with the stomach, tincture of orange-peel, of cardamom, or of ginger, or a drop or two of chloroform, may be added to each dose, or it may be dissolved in an aromatic infusion. It is said that ergot removes the cerebral symptoms caused by this medicine (Schilling).

Various formulæ for administering salicylic acid are really solutions of its salts: *e. g.* $\mathcal{R}$. Salicylic Acid 120 grs.; Solution of Acetate of Ammonium f ʒij; Water f ʒvj.—*M.* Each fluidounce contains 15 grs. of the salt. *Or.* $\mathcal{R}$. Salicylic Acid 100 grs.; Borax 80 grs.; Water f ʒxvj.—*M.* *Or.* $\mathcal{R}$. Salicylic Acid 120 grs.; Borax 60 grs.; Glycerin q. s.—Mix the acid and borax with f ʒiv of glycerin, heat until solution is complete, and add glycerin to make the whole measure f ʒj. This contains 25 per cent. of the acid. *Or.*, again: $\mathcal{R}$. Peppermint-water. f ʒiv; acetate of potassium. ʒiss; salicylic acid, ʒss; lemon syrup. f ʒij. Dissolve the acetate of potassium in the peppermint-water, introduce the acid gradually with agitation until dissolved, and then add the syrup. Of this solution each dessert-spoonful contains 10 grains of salicylic acid, free or combined. For external use a solution of 1 part of the acid in 300 parts of water is recommended. Cotton saturated with a hot solution of the acid, from 3 to 10 per cent. strong, and properly dried, has been used as a surgical dressing.

ACIDUM SUCCINICUM.—SUCCINIC ACID.

Sal succini volatile.—*Acide succinique*, Fr.; *Bernsteinsäure*, G.

Formula $\text{H}_2\text{C}_4\text{H}_4\text{O}_4 = (\text{CH}_2)_2(\text{COOH})_2$. Molecular weight 118.

Origin.—Succinic acid exists in amber, in unripe grapes, in different species of *Lactuca*, *Artemisia*, and other plants, and in many animal liquids. It is formed in the oxidation of wax, spermaceti, butyric, stearic, and some other fatty acids; of valerianic acid, benzoic acid, and other organic compounds; in the vinous fermentation of sugar; by the deoxidation or under the influence of casein as a ferment from asparagin, tartrates, malates, aconitates, fumarates, etc. It was observed by Agricola (1550), and recognized as an acid by Lemery (1675).

Preparation.—For medicinal use, succinic acid is prepared by the dry distillation of coarsely-powdered amber from a glass retort, which is entirely imbedded in sand and the short neck of which is connected with a large receiver. The heat is gradually increased to about 280°C . (536°F .), and kept at this temperature as long as white vapors are evolved. The distillate consists of succinic acid crystallized in the neck of the retort, while the receiver contains oil of amber and an aqueous liquid which, according to Marsson (1850), contains, besides succinic acid, also acetic, propionic, butyric, valerianic, and capronic acids. On concentrating this solution more succinic acid is obtained. (See *OLEUM SUCCINI*.)

Properties.—The impure acid is in yellowish or brownish prismatic crystals, which have the odor of oil of amber and an acid, empyreumatic taste. It begins to volatilize at 100°C . (212°F .), fuses between 160° and 180°C . (320° and 356°F .), and boils at 235°C . (455°F .), giving off acid vapors, dissolves in 2 parts of boiling and 28 parts of cold water, and is freely soluble in warm alcohol, slightly in ether, and insoluble in oil of turpentine. The pure acid is inodorous, is scarcely affected by oxidizing agents, and by fusing potassa is converted into oxalic acid. With the alkalies and magnesia it forms salts which are readily soluble in water; the salts with most other metals are less freely or not at all soluble in water, but dissolve in solution of potassium acetate. The neutral solutions produce, with ferric chloride, red-brown precipitates.

Tests.—A concentrated aqueous solution of the acid should not produce a precipitate with potassium acetate (absence of tartaric acid), nor with chloride of barium (sulphuric

acid), chloride of calcium (oxalic acid), sulphuretted hydrogen, nor, after neutralization, with sulphhydrate of ammonium (metals). When treated with soda in excess an ammoniacal odor should not be generated, and when heated upon platinum-foil the odor of caramel should not be observed (sugar), nor should finally any fixed residue be left (salts).

Pharmaceutical Uses.—It is employed for preparing

Liquor Ammonii Succinatis (Succinici, *P. G.* 1872), *s. Liq. cornu cerri succinici*. 1 part of succinic acid is dissolved in 8 parts of warm water, and neutralized by 1 part or a sufficient quantity of pyro-oleous carbonate of ammonium; the solution is set aside for 24 hours and then filtered. It has a brownish or brown color, remains clear when mixed with three times its weight of alcohol, and when evaporated and ignited leaves no residue. Pure ammonium succinate is sometimes used for estimating the iron in ferric salts.

Medical Action and Uses.—There is no reason to believe that this acid possesses any active properties or medicinal virtues. It has been taken in doses of from 60 to 120 grains without any definite effects. It is excreted partly by the skin, but chiefly with the urine either unchanged, or, as has been asserted, in the form of hippuric acid. It has been alleged to raise the pulse, promote diaphoresis and the bronchial secretion, and augment the activity of the nervous centres; and has been prescribed in *rheumatism*, *bronchitis*, and *hysteria* and various other spasmodic affections. Even if its apparent utility had been demonstrated, the objection may fairly be made that the acid was not used alone, but as a succinate of ammonium and with empyreumatic oils, etc. The *dose* of the acid may be stated to be between 5 and 15 grains (Gm. 0.30–1.00).

ACIDUM SULPHURICUM, *U. S.*, *Br.*—SULPHURIC ACID.

Acidum sulfuricum, *P. G.*—*Oil of vitriol*, *E.*; *Acide sulfurique*, *Huile de vitriol*, *Fr.*; *Schwefelsäure*, *Vitriölöl*, *G.*

Formula H_2SO_4 . Molecular weight 98. Strength 96 to 97 per cent. Spec. grav. 1.840 to 1.843.

Diluted Sulphuric Acid. Strength 10 per cent. *U. S.*, 13.5 per cent. *Br.* Spec. grav. 1.067 *U. S.*, 1.094 *Br.*

Origin.—Sulphuric acid is found in the free state in certain springs emanating from volcanoes and in the salivary glands of some mollusks, but it mostly occurs combined with various bases both in the mineral and organic kingdoms. At an early date the acid was known to the alchemists, but its preparation from “calcined vitriol” (ferrous sulphate) was first described by Basilus Valentinus in the fifteenth century. Lavoisier (1777) determined it to be composed of sulphur and oxygen, and Richter (1795) ascertained the percentage of the two elements nearly correct. In the manufacture of sulphuric acid Roebuck and Garbett (1746) replaced the glass vessels by a lead chamber, and Lafolie (1774) introduced the use of steam.

Preparation.—1. **SULPHURIC ACID.** Sulphur or iron pyrites is burned in a furnace arranged in such a manner that the sulphurous acid gas is mixed with atmospheric air; in the same furnace, by the heat of the burning sulphur, nitric acid is generated from a mixture of nitrate of sodium and sulphuric acid, the vapors of nitric acid being carried with the mixed sulphurous acid and air into a large leaden chamber, where the current of these gases comes in contact with a jet of steam. The sulphurous acid, in the presence of water, acts upon the nitric acid thus: $3\text{SO}_2 + 2\text{HNO}_3 + 2\text{H}_2\text{O} = 2\text{NO} + 3\text{H}_2\text{SO}_4$. Nitric oxide and sulphuric acid are produced; the latter, being condensed, dissolves in the water, which covers the floor of the lead chamber to the depth of about 2 inches. The nitric oxide, at the moment of its formation, is at once oxidized by the oxygen, which entered the lead chamber with the sulphurous acid gas, into nitrous and hyponitric acids, N_2O_3 and NO_2 , both of which are decomposed in the presence of sufficient water into nitric acid and nitric oxide, the reaction being explained by the following equations: $3\text{N}_2\text{O}_3 + \text{H}_2\text{O} = 2\text{HNO}_3 + 4\text{NO}$ and $3\text{NO}_2 + \text{H}_2\text{O} = \text{NO} + 2\text{HNO}_3$. The nitric acid regenerated in this manner again reacts upon some sulphurous acid gas, oxidizing it to sulphuric acid and becoming reconverted into nitric oxide. It will be observed that, theoretically, a given quantity of nitric acid is capable of oxidizing an unlimited amount of sulphurous acid; the limit in practice is occasioned by the loss of the nitrogen compounds which remain dissolved in the diluted sulphuric acid finally drawn from the chambers. If the nitric acid could be used once only, it is obvious that 170 parts or 2 molecules of the nitrate of sodium could furnish sufficient merely to oxidize the sulphurous acid resulting from 96 parts or 3 atoms of sulphur, while practically about 5 or 6 parts of sodium nitrate are sufficient.

Through the condensation of the sulphuric acid in the chamber, room is made for a fresh quantity of sulphurous acid gas and air, while the nitrogen contained in the air accumulates and is removed through a chimney after it has finally passed through a lead chamber filled with coke, over which sulphuric acid is made to trickle, thus dissolving the nitric oxide contained in the nitrogen. The acid, thus charged with this gas, most likely in the form of a nitro-sulpho-compound, is passed in the form of spray into another smaller chamber placed near the furnace, so that the sulphurous acid and air, in passing through this, may carry the nitric oxide into the first large lead chamber, there to be utilized in effecting the oxidation of the sulphurous acid. Instead of introducing nitric acid vapors with the mixed sulphurous acid and air, as described above, the apparatus is sometimes arranged in such a manner that in the second chamber a number of earthen vessels nearly filled with nitric acid by means of a tube from the top of the chamber are placed upon shelves above each other; or where nitrous acid is obtained in sufficient quantity, as in the manufacture of oxalic acid, this is used in place of nitric acid, with the same success.

The number of lead chambers varies from 4 to 7, and the gases are made to pass through all in succession. The central one is larger, and placed several feet lower than the others, so that the sulphuric acid condensing in the latter will flow into the former. When the acid in the chamber, often designated as *chamber acid*, has attained the specific gravity 1.52 to 1.58, it is drawn off and evaporated in shallow leaden pans until it has reached a density of 1.70 to 1.75. In this operation sulphurous, nitrous, and nitric acids are expelled, and sulphates of iron, lead, and calcium deposited, the salts resulting from the corrosion of the vessels and the impurities of the water. The acid is now usually dark-colored, due to accidental organic admixtures. If further evaporated in the lead pans the metal would be corroded and much acid volatilized. The final concentration must therefore be effected in platinum stills or glass retorts placed in a sand-bath, the distillation being continued as long as a weak acid passes over or until the residue has the desired density. For the preparation of a *pure* sulphuric acid, however, the commercial acid must be distilled from a glass retort, which is placed in a deep sand-bath surrounded by sand and covered with a metallic hood; the neck of the retort is connected without luting with a suitable receiver, which is changed when about one-eighth or one-sixth of the acid has come over; the subsequent portion will have the required specific gravity. It is important that an acid free from arsenic should be selected for distillation.

2. NORDHAUSEN OIL OF VITRIOL, so named because it was first manufactured near Nordhausen in Saxony, is obtained from ferrie sulphate, which is made by allowing ferrous sulphate to oxidize in the air. It is distilled in small earthen retorts, which are placed horizontally in a furnace and connected with earthen receivers. Each retort is charged with from 2 to 3 pounds of the dry salt, and yields about 50 per cent. of acid, which consists of about 1 molecule each of sulphuric anhydride and hydrogen sulphate, $\text{SO}_3 \cdot \text{H}_2\text{SO}_4$. Ferric oxide remains behind, and is used under the name of *colcothar* or *rouge* for polishing glass and metals.

3. ACIDUM SULPHURICUM DILUTUM, *U. S.*, *Br.* Diluted Sulphuric Acid, *E.*; Acide sulfurique diluë, *Fr.*; Verdünnte Schwefelsäure, *G.*—Take of Sulphuric Acid 1 part; Distilled Water 9 parts (5 parts. *P. G.*). Add the acid gradually, with constant stirring, to the distilled water.—*U. S.*, *F. Cod.*

The direction of the Pharmacopœias to add *the acid to the water* must be observed in all cases, and more particularly if large quantities of acid are to be diluted. During the mixing of the two liquids, which is best performed in a porcelain dish or beaker-glass, a considerable elevation of temperature takes place, causing a portion of the water to evaporate; the weight of the cooled mixture should therefore be made up to 10 parts by the addition of distilled water. Filtration through paper or decantation is necessary only when pure sulphuric acid has not been used, to remove the sulphate of lead, which is deposited from the commercial acid on diluting with water. The British Pharmacopœia dilutes 7 fluidounces of sulphuric acid with sufficient water to make the liquid, when cooled to 15.5°C . (60°F .), measure $83\frac{1}{2}$ fluidounces, or 1350 grains of the acid are diluted as before to measure 1 pint (Imperial). The German Pharmacopœia admits for diluted sulphuric acid a specific gravity varying between 1.110 and 1.114.

Purification.—To remove nitrogen compounds from strong sulphuric acid, Maxwell Lyte recommends (1864) the addition to it of $\frac{1}{4}$ or $\frac{1}{2}$ per cent. of oxalic acid, and then exposure to heat until this compound is completely decomposed. To remove arsenic, Busy and Buignet (1863 and 1864) oxidize this metal, if present as arsenious acid, to arsenic acid, and then distil nine-tenths of the sulphuric acid after having previously added some sulphate of ammonium. A. Buchner (1863) avoids distillation in such a case

by reducing the arsenic, if present as arsenic acid, to arsenious acid by heating the sulphuric acid with a little charcoal. Hydrochloric acid gas is then passed through the liquid, and the arsenic is entirely eliminated from the hot acid as chloride of arsenic.

Properties.—1. **SULPHURIC ANHYDRIDE** or **ANHYDROUS SULPHURIC ACID**. This distils first when Nordhausen oil of vitriol is heated. At a low temperature it forms long, colorless prisms having in quantity somewhat the aspect of asbestos. It fuses at about 20° C. (68° F.) to a colorless liquid, boils above 35° C. (95° F.), and dissolves in all proportions of oil of vitriol. When kept at a temperature below 25° C. (87° F.) it is gradually converted into a modification which is slightly soluble in oil of vitriol and melts slowly above 50° C. (122° F.), at the same time passing into the former kind. Both kinds attract moisture with great avidity, and in contact with the air give off white fumes. Its composition is SO_3 .

2. **NORDHAUSEN OIL OF VITRIOL**. This was official in Germany under the name of *Acidum sulphuricum fumans*. It is an oily liquid, emitting white suffocating fumes, and having a specific gravity of from 1.860 to 1.900. It is usually of a brownish color, due to organic matter. Near 0° C. (32° F.) it forms colorless flat crystals, and between 40° and 50° C. (104° and 122° F.) it commences to boil, sulphuric anhydride distilling over; on continuing the heat an acid is finally obtained which boils at 338° C. (see below).

3. **COMMERCIAL SULPHURIC ACID**, **ACIDUM SULFURICUM CRUDUM**, *P. G.* It forms a colorless or brownish, inodorous, oily liquid, intensely acid and corrosive, and having a specific gravity of not less than 1.830 (*P. G.*). It holds a small quantity of lead sulphate in solution, which, however, does not render it unfit for pharmaceutical purposes if it is otherwise pure, more particularly free from arsenic, since that salt is precipitated when the acid is diluted with water or alcohol. It is also liable to contain small quantities of nitric, hydrochloric, and sulphurous acid, iron and other metals, lime, ammonia, and other alkalis.

4. **PURE SULPHURIC ACID**. It resembles the colorless crude acid in its physical properties, and, like it, is very hygroscopic. When cooled to about -35° C. (-31° F.) it congeals, and heated to 338° C. (640° F.) it boils, yielding a colorless gas producing dense white fumes when in contact with the atmosphere, and finally evaporates without leaving any residue. The boiling is usually accompanied with violent concussions. Weaker acids boil at a lower temperature, the strength and density being increased until the boiling-point mentioned above has been reached, when the acid contains 1.5 per cent. H_2O and 98.5 per cent. H_2SO_4 (Marignac, 1853). Pure hydrogen sulphate melts, according to Marignac, at 10.5° C. (51° F.), and has at 0° C. (32° F.) the density 1.854, and at 12° C. (53.6° F.) 1.842, in both cases compared with water of the same temperature. The affinity of concentrated sulphuric acid for water is so great that organic compounds left in contact with it are charred, while the acid at the same time acquires a brown color.

The specific gravities of sulphuric acid of different strength, as ascertained by Vauquelin, Darcet, Bineau, Dalton, Ure, and Kolb, vary in some cases considerably. The foregoing is Bineau's table for a temperature of 15°C . (59°F).

Pure sulphuric acid unites with water and alcohol in all proportions, forming transparent liquids; a white turbidity indicates lead sulphate, which becomes black with hydrosulphuric acid. Arsenic would be indicated by a yellow precipitate occurring in the diluted acid with sulphuretted hydrogen, or more rapidly by nitrate of silver in applying Marsh's test or by Fleitmann's method (see page 28). A cold concentrated solution of ferrous sulphate poured upon the surface of the concentrated acid does not develop a purplish-brown color where the two liquids unite, showing the absence of nitrogen oxides.

The pharmacopœias require the official acid to contain between 96 and 97 per cent. of H_2SO_4 ; 49 parts of it, or $\frac{1}{2}$ molecule, will be exactly neutralized by between 96 and 97 parts of potassium bicarbonate, or 4.9 Gm. of the acid by not less than 96 Cem. of the volumetric solution of soda. The British Pharmacopœia requires for 1000 grain-measures of the latter 50.6 grains of the acid, which corresponds to 96.8 per cent. of H_2SO_4 , equal to 79 per cent. SO_3 .

Sulphuric acid is one of the strongest of acids. It is bibasic, and forms normal and acid salts, which are generally crystallizable and soluble in water. The sulphates of barium and lead are entirely insoluble in water and diluted acids; hence their soluble salts furnish the best reagents for sulphuric acid in its uncombined and combined state.

5. DILUTED SULPHURIC ACID. It has the general properties of the strong acid, but is not of an oily consistence, and is less caustic. It differs from the other diluted mineral acids in containing 10 per cent. of the official, but not of absolute, sulphuric acid; accordingly, 4.9 Gm. of it are neutralized by not less than 9.6 Cem. of the volumetric solution of soda. The British Pharmacopœia requires the diluted acid to contain 11.14 per cent. of SO_3 , equal to 13.65 per cent. of H_2SO_4 ; of it, 359 grains are neutralized by 1000 grain-measures of the volumetric solution of soda.

Impurities.—The most important impurities, arsenic, lead, and nitrogen oxides, have been mentioned before. Saline additions, sometimes made to increase the specific gravity of weaker acids, are recognized by the fixed residue left on evaporating a small quantity from a platinum dish or crucible. Sulphurous and nitrous acid rapidly decolorize potassium permanganate. For the detection of the former Warington recommends (1868) the suspension in a quart bottle, half filled with the sulphuric acid, of a strip of paper colored blue by iodide of starch, which will be bleached by the sulphurous acid; a paper covered with starch and iodide of potassium, suspended in a similar manner, becomes blue in the presence of nitrogen oxides.

Arsenic is found principally in sulphuric acid manufactured from pyrites, more rarely if made from sulphur; for this reason the sulphuric acid manufactured in the United States is often free from this contamination.

Pharmaceutical Uses.—Sulphuric acid is largely used in numerous pharmaceutical processes for the liberation of acids (hydrocyanic, hydrochloric, nitric, citric, tartaric); in the preparation of alkaloids, pyroxylon, ether, and oil of wine; for generating hydrogen with zinc and water; for decomposing certain organic compounds, as in the purification of chloroform; and for the preparation of sulphurous acid, the medicinal sulphates, and of *Acidum sulphuricum aromaticum*.

MIXTURA SULFURICA ACIDA, *P. G.*, s. *Elixir acidum Halleri*. It is prepared by dropping 1 part of pure sulphuric acid into 3 parts of alcohol, and stirring continually; it is a colorless liquid, having nearly the specific gravity of water. It is an alcoholic solution of sulphovinic acid, into which the sulphuric acid is gradually converted. Colored by red poppy-petals, it is *Eau de Rabel* of the French Codex.

MIXTURA VULNERARIA ACIDA, s. *Aqua vulneraria Thedenii*.—Theden's vulnerary water, *E.*; Eau d'arquebusade, *Fr.*; Theden's Wundwasser, *G.* It is a mixture of diluted sulphuric acid 1 part; vinegar 6 parts; alcohol (sp. grav. .892) 3 parts; and clarified honey 2 parts.—*F. Cod.*

MICHEL'S PASTE is a mixture of powdered asbestos 1 part and concentrated sulphuric acid 3 parts. It should be freshly prepared when needed. Similar are the caustic pastes of Rust, Velpeau, and Ricord, in which the asbestos is replaced by saffron, liquorice-root, and powdered charcoal respectively.

Physiological Action.—In a concentrated state sulphuric acid abstracts water from organized matter, turning it black and exposing its carbonaceous elements in the form of charcoal. Injected into the veins, it coagulates the blood and carbonizes it. When swallowed in a concentrated form it destroys all the tissues it touches, and in this con-

dition, as well as when somewhat less strong, it produces severe pain in the throat, œsophagus, and stomach, with violent efforts at vomiting, and collapse. The urine is sometimes albuminous or bloody. The mind remains clear. Even when death does not directly occur, it often does so at a later period, owing to stricture of the œsophagus or intestine resulting from ulceration of the mucous membrane. In medicinal doses it diminishes thirst, restrains sweats depending on debility, improves the appetite, probably by stimulating the stomach, acidifies the secretions, and reduces the frequency of the pulse. Its action upon the teeth, even when it is greatly diluted, is exceedingly injurious, and by continued use it exhausts the digestive functions and causes diarrhœa, with debility and emaciation.

Medical Uses.—The corrosive action of sulphuric acid has been made use of to correct inversion and also eversion of the eyelid (*ectropion* and *entropion*) by forming an eschar upon the convex or projecting surface of the part, which in cicatrizing contracts the tissues and corrects the deformity. It has sometimes been employed as an escharotic application to various infecting or ill-conditioned *ulcers*, particularly in *gangrene* of the mouth and in *caries* of the bones, and also for the extirpation of *cancers*. In the last case a paste is applied to the tumors formed of asbestos and powdered sulphate of zinc, or saffron, saturated with sulphuric acid. The operation is tedious, very painful, and as uncertain as any other for the same purpose. An ointment composed of 1 part of the acid to 8 parts of lard has been recommended for *tinea capitis*; and in the treatment of *scabies* it is often successful either in ointment or lotion, and has the advantage over sulphur ointment of being free from any unpleasant smell. Internally, sulphuric acid in the diluted or aromatic form is much used in chronic diseases with a tendency to a dissolution of the blood, such as *scurvy* and *purpura*, as well as in other and especially uterine passive *hæmorrhages*. It is thought to be particularly useful in mucous hæmorrhages and fluxes, because the acid is eliminated by the mucous membranes; but this explanation would not apply to blood diseases, whether chronic or acute, and especially to *fevers* of a low type, in which it is reputed to be efficient. Still less would it apply to *colliquative sweating*, for which this medicine is one of the very best remedies. Nor can it be assumed to explain the efficacy of the acid in *diarrhœa*, *cholera morbus*, and even *epidemic cholera*. In the last-mentioned cases the most probable view is that its operation is local and in its nature astringent. So far as it acts by being taken into the blood, it probably does so in the same manner, but from within instead of from without. Its apparent power of preventing as well as of curing epidemic cholera appears distinctly to be owing to the astringent influence by which it prevents the absorption of the cholera poison from the alimentary canal, the ordinary channel of its introduction, and at the same time limits the transudation of the contents of the blood-vessels into the bowels. Its value as a prophylactic against cholera is not so well authenticated. Its efficacy in *painter's colic* is generally admitted. It is administered with water, in the proportion of about 2 fluid-drachms (Gm. 8) in 3 pints of water in the course of 24 hours. If it is useful, as alleged, in curing *gravel* and *stone*, its utility is probably due to a tonic action upon the stomach. It has sometimes appeared to remove *tape-worms*, perhaps by its physical action upon these parasites.

As *antidotes* to poisoning by sulphuric acid, chalk, magnesia, carbonate of magnesia, and the alkaline carbonates may be administered.

The *dose* of the strong acid is 1 or 2 drops (Gm. 0.06–0.13) dissolved in not less than 4 ounces of water; of the diluted acid, from 10 to 30 drops (Gm. 0.60–2.00) may be given in the same way.

ACIDUM SULPHURICUM AROMATICUM, *U. S.*, *Br.*—AROMATIC SULPHURIC ACID.

Tinctura aromatica acida, *Elixir vitrioli Mynsichti*.—*Elixir of vitriol*, *E.*; *Elixir vitriolique*, *Teinture (Alcoolé) aromatique sulfurique*, *Fr.*; *Saure aromatische Tinctur*, *Mynsicht's Elixir*, *G.*

Strength of H_2SO_4 : 19.2 per cent. *U. S.*, 13.4 per cent. *Br.* Spec. grav. .955 *U. S.*, .027 *Br.*

Preparation.—Add gradually Sulphuric Acid 200 parts (4 oz. av.) to Alcohol 700 parts (14 oz. av., or 16½ fluidounces), and allow the mixture to cool. Then add to it Tincture of Ginger 45 parts ($\frac{9}{16}$ oz. av., or 1 fluidounce). Oil of Cinnamon 1 part (8½ grains, or 8 minims), and enough Alcohol to make the product weigh 1000 parts (20 oz. av., or 20½ fluidounces).—*U. S.*

Take of Sulphuric Acid 3 fluidounces, or 2479 grains by weight; Rectified Spirit 2 pints (Imperial); Cinnamon-bark in coarse powder 2 ounces; Ginger in coarse powder 14 oz. Mix the acid gradually with the spirit, add the cinnamon and ginger, macerate for 7 days, agitating frequently, then filter.—*Br.*

This preparation has been dismissed from both the French and German Pharmacopœias.

Properties.—The first formula is essentially that suggested by T. N. Jamieson in 1867 as a substitute for one directing, like the last two formulas, the maceration of the aromatics in the mixture of alcohol and sulphuric acid, whereby a preparation of a deep brown-red color is obtained, which in the course of time deposits an unsightly precipitate, due perhaps to modified tannin. The preparation obtained by the new pharmacopœial process is of a light-straw color, and, while it yields only a slight precipitate, has about the same aromatic properties as the former.

On mixing sulphuric acid with alcohol the temperature rises and some sulphovinic (ethylsulphuric) acid is produced, the quantity of which slowly increases with the age of the preparation. For the same amount of sulphur this acid has only one-half the saturating power of sulphuric acid; the acidimetric test must therefore vary with the age of this preparation, and when fresh and made at a low temperature 9.8 Gm. of the acid, properly diluted with water, will require for complete neutralization 38.4 (*U. S.*), 26.8 (*Br.*) Ccm. of the volumetric solution of soda; the *U. S. Pharmacopœia* says "not less than 3.6 Ccm.," which will probably be the limit after keeping for several months. The British Pharmacopœia requires 830 grain-measures of the soda solution for the neutralization of 304.2 grains (6 fluidrachms) of its aromatic sulphuric acid.

Medical Uses.—This preparation is preferable to any other form of sulphuric acid for internal administration. It is peculiarly adapted to the treatment of *gastro-intestinal disorders*, for which the simple acid is also appropriate, and of the *colliquative sweats* of phthisis and other hectic affections. Dose, from 10 to 20 drops (Gm. 0.60–1.30).

ACIDUM SULPHUROSUM, *U. S.*, *Br.*—SULPHUROUS ACID.

Sulphurous anhydride, Sulphur dioxide, E.; *Acide sulfureux*, Fr.; *Schweflige Säure*, G. Formula, SO_2 . Molecular weight 64. Strength 3.5 per cent. *U. S.*, 9.2 per cent. *Br.* Specific gravity, 1.022 *U. S.*, 1.04 *Br.*

Origin and Production.—Sulphurous acid was first distinguished from sulphuric acid by Stahl (1697); its properties in the gaseous state were studied by Priestley (1775), and Lavoisier (1777) showed that it contains less oxygen than sulphuric acid. It is met with in the exhalations of active volcanoes, and is produced on the burning of sulphur and when concentrated sulphuric acid is heated with charcoal or with organic matters, with copper, mercury, or other metals. The official process is as follows:

Preparation.—Take of Sulphuric Acid 14 parts; Charcoal in coarse powder 2 parts; Distilled Water 100 parts. Pour the acid upon the charcoal previously introduced into a glass flask, and mix the two well together. By means of a glass tube and well-fitting corks connect the flask with a wash-bottle, which is one-third filled with water and fitted with a cork having three perforations. Into one of these perforations insert a safety-tube, which should reach nearly to the bottom of the bottle; into the remaining perforation fit a glass tube and connect it with a bottle which is about three-fourths filled by the distilled water. This tube should dip about an inch below the surface of the water. By means of a second tube connect this bottle with another bottle containing a dilute solution of carbonate of sodium, to absorb any gas which may not be retained by the distilled water. Having ascertained that all the connections are air-tight, apply a moderate heat to the flask until the evolution of gas has nearly ceased, and during the passage of the gas keep the bottle containing the distilled water at or below 10° C. (50° F.) by surrounding it with cold water or ice. Finally, pour the sulphurous acid into glass-stoppered, dark amber-colored bottles, and keep them in a cool and dark place.—*U. S.*

In these directions neither the size of the wash-bottle nor the amount of water to be used for washing the gas is given; an 8-ounce or 12-ounce bottle containing 2 or 3 ounces of water will be found to answer the purpose if about 10 ounces of sulphuric acid are used; and if a safety-tube be inserted in the apparatus the delivery-tube may be allowed to reach to near the bottom of the distilled water. The gas which is not absorbed must, to avoid inconvenience, be conveyed either into the open air, into a flue, or, as directed above, into an alkaline solution, where it will be retained.

The process of the British Pharmacopœia is essentially the same: the gas evolved from

4 fluidounces of sulphuric acid and 1 ounce of wood charcoal is washed by passing it through 2 ounces of water and conducted into 20 fluidounces of distilled water.

The charcoal acts as a reducing agent upon the sulphuric acid, generating carbonic and sulphuric anhydrides and water; thus: $C_2 + 4H_2SO_4 = 2CO_2 + 4SO_2 + 4H_2O$. The gas is therefore contaminated with carbon dioxide, which will likewise be retained by the distilled water to a slight extent. A purer acid is obtained by heating copper clippings with concentrated sulphuric acid, when sulphate of copper and sulphurous acid will be produced: $Cu_2 + 4H_2SO_4 = 2CuSO_4 + 2SO_2 + 4H_2O$. Double the quantity of sulphuric acid will be necessary to produce the same amount of sulphurous acid as is produced by the official process.

Properties and Tests.—Sulphur dioxide consists of 1 measure of gaseous sulphur and 2 of oxygen, condensed to 2 measures; it is a colorless, irrespirable gas, has a pungent and suffocating odor, and condenses to a liquid at $-17.8^\circ C.$ ($0^\circ F.$) or under a pressure of 4 or 5 atmospheres; this liquid boils briskly on coming into contact with ice. Water dissolves at $10^\circ C.$ ($50^\circ F.$) 51 volumes, and at $20^\circ C.$ ($68^\circ F.$) 36 volumes, of sulphur dioxide; the solution contains sulphurous acid, $H_2SO_3 = (OH)_2SO$, and when saturated at ordinary temperature has, according to Anthon (1860), the density 1.046 and contains 9.54 per cent. SO_2 . The density of sulphurous acid of different strength has been ascertained as follows:

Per ct. SO_2 .	Specific gravity.			Per ct. SO_2 .	Specific gravity.			Per ct. SO_2 .	Specific gravity.		
	Anthon, med. temp.	Scott, $15^\circ C.$	Hager, $17.5^\circ C.$		Anthon, med. temp.	Scott, $15^\circ C.$	Hager, $17.5^\circ C.$		Anthon, med. temp.	Scott, $15^\circ C.$	Hager, $17.5^\circ C.$
10.00		1.052	1.044	6.68	1.027			3.82	1.016		
9.54	1.046			6.50		1.035	1.027	3.50		1.019	1.014
9.50		1.049	1.041	6.00		1.033	1.025	3.00		1.017	1.012
9.00		1.047	1.039	5.72	1.023			2.86	1.013		
8.59	1.036			5.50		1.030	1.023	2.50		1.014	1.010

7.63	1.031			4.50		1.025	1.019	1.50		1.008	1.006
7.50		1.040	1.033	4.00		1.022	1.017	0.95	1.005		
7.00		1.037	1.030								

Strength and density, as given by the British Pharmacopœia, correspond with the above table, but not the figures given by the U. S. Pharmacopœia. Both authorities determine the strength by iodine, 1 atom of which will be converted into hydriodic acid by $\frac{1}{2}$ molecule of sulphur dioxide; hence 3.2 Gm. of the pharmacopœial sulphurous acid, properly diluted, will not acquire a permanent blue color with starch-paste, until at least 92 Ccm. (*Br.*), 35 Ccm. (*U. S.*) of the volumetric solution of iodine have been added, or 1000 grain-measures of the latter should oxidize 34.7 (*Br.*), 13.2 (*U. S.*) grains of sulphurous acid; $I_2 + H_2SO_3 + H_2O$ yield $H_2SO_4 + 2HI$.

The aqueous solution of sulphurous acid evaporates by heat without leaving any residue; in contact with air it is oxidized to sulphuric acid, and when exposed to light it acquires the property of precipitating sulphide of silver from nitrate of silver. Chloride of barium, slightly acidulated with hydrochloric acid, yields no precipitate with it, or only a slight turbidity. The gas remains with the water when the solution freezes, and at the boiling temperature some time must elapse before it is entirely expelled.

Sulphurous acid is a powerful deoxidizing agent, abstracting oxygen from permanganic, chromic, iodic, arsenic, nitric, and other acids, from ferric, mercuric, argentic, and other salts, and from most vegetable colors, thereby bleaching the latter. It yields hydrogen sulphide and water when in contact with nascent hydrogen. It displaces carbonic acid from its saline compounds, and yields salts which generally are sparingly soluble in water, except the alkaline sulphites; they are inodorous, have a somewhat acrid taste, and on ignition are converted into sulphate and sulphide, or sulphur dioxide is given off, the metallic oxide remaining.

Pharmaceutical Uses.—Sulphurous acid is employed in the preparation of sodium, calcium, and other sulphites, and of calomel by the wet process, and serves as a powerful reducing agent. In pharmacy and the arts it is used for bleaching sponges, bones, straw, and other organic matters, for removing fruit-stains, and for arresting or preventing fermentation and putrefaction.

Medical Uses.—Sulphurous acid is chiefly used for the purpose of destroying or preventing the development of those low forms of cryptogamic life which are supposed

to be the essential element of certain diseases and of the process of fermentation. *Favus* of the scalp and hairy portions of the face is treated by means of lotions containing 1 part of the acid to 3 of water, after the crusts have been removed by means of emollient poultices. It has also been used successfully in the cure of *scabies*. As a lotion for recent *wounds* it has been thought to allay pain, diminish suppuration, and promote cicatrization; and as a gargle it is recommended for ulcerated and gangrenous *pharyngitis*. In many other local affections requiring a stimulant and antiseptic treatment it may be used with advantage. It may be given internally in the treatment of *urticaria* and to prevent the *flatulence* depending upon dyspeptic fermentation, but for the latter purpose the sulphites are preferable. This acid, as it is formed by burning sulphur, has been much used for *disinfecting* shops, hospital wards, etc. which have been occupied by the sick or which are contaminated by foul odors.

The *dose* of sulphurous acid is from 1 to 3 fluidrachms (Gm. 4-12), largely diluted.

ACIDUM TANNICUM, U. S., Br., P. G.—TANNIC ACID.

Acidum gallo-tannicum, *Tanninum*.—*Tannin*, E.; *Acide tannique*, *Tannin*, Fr.; *Gerbsäure*, *Tannin*, G.

Formula $C_{14}H_{10}O_9 = (C_6H_2)_2 \cdot ([OH]_2 \cdot COOH)_2O$. Molecular weight 322.

Origin and Varieties.—Compounds having acid properties and an astringent taste, producing dark-colored solutions or precipitates with salts of iron, and precipitating gelatin and albumen from their solutions, are called by the generic name of tannins. The reaction of tannins with metallic salts, and one of their principal products, leather, were known in ancient times; but Deyeux (1793) and Seguin (1795) first proved tannin to be a distinct compound. The tannins are conveniently arranged into two groups, according to the color produced with ferric salts, which is either dark-green or dark-blue. A large number of plants contain tannin of the latter group, differing, however, from the officinal tannic acid in not furnishing gallic or pyrogallic acid. The tannin obtained from nutgalls is, for this reason, distinguished from the others by the prefix *gallo*. Gallotannic acid has been found in the officinal galls, in Chinese and Japanese galls, in the cups of the fruit of some oaks, and in the leaves of Italian sumach, *Rhus Coriaria*, *Linne*.

Preparation.—Take of Nutgall in fine powder, Ether, each a sufficient quantity. Expose the nutgall to a damp atmosphere for 2 or 3 days, and afterward add sufficient ether to form a soft paste. Let this stand in a well-closed vessel for 24 hours; then, having quickly enveloped it in a linen cloth, submit it to strong pressure in a suitable press, so as to express the liquid portion. Reduce the pressed cake to powder, mix it with sufficient ether, to which one-sixteenth of its bulk of water has been added to form again a soft paste, and express as before. Mix the expressed liquids, and expose the mixture to spontaneous evaporation until, by the aid subsequently of a little heat, it has acquired the consistence of a soft extract; then place it on earthen plates or dishes and dry it in a hot-air chamber at a temperature not exceeding 212° F.—*Br*.

The process adopted by the pharmacopœias is that proposed by Dominé in 1844, and based upon that of Lecommet, first published in 1836, the important modification being the exposure of the powdered galls to a damp atmosphere, and the addition of water to the ether in order to supply the water requisite for rendering the tannin soluble in the ether. That water is absolutely necessary was noticed by Pelouze (1834), who percolated powdered nutgalls with commercial ether containing water—a process suitable for preparing tannin on a small scale; the percolate separates into two slightly-colored layers, the lower of which is a very concentrated solution of tannin. Dominé's plan brings about the same result in less time and with much less ether, for which reasons it is well adapted for the preparation of tannin on a large scale. Mohr, Guibourt, and others used a mixture of ether, alcohol, and water.

Gallotannic acid is insoluble in absolute ether, but in the presence of a little water a definite compound appears to be formed of tannin and ether, or with water in addition thereto, which is insoluble in ether, but may be dissolved in water; the ether retained in this syrupy liquid is larger in quantity than would be dissolved by the same amount of water. The complete drying of the tannin is effected at a somewhat elevated temperature, by which the volatile ingredients of the syrupy liquid cause the latter to froth up, leaving the tannin behind in loose, porous masses somewhat sponge-like in appearance. It is scarcely necessary to state that during the entire process contact with most metals, notably with iron, must be avoided; the operations are best performed in glass, porcelain, or earthen vessels.

Properties.—Tannic acid, thus prepared, has a yellowish-white color, frequently of a slight greenish tint. It has a strongly astringent taste, and is freely soluble in water, alcohol, acetone, oil of bitter almond, and in 6 parts of glycerin; but remains pulverulent when in contact with anhydrous ether which is free from alcohol, and is likewise insoluble, or nearly so, in chloroform, petroleum benzin, benzol, carbon bisulphide, and in most fixed and volatile oils. The solutions have an acid reaction. Tannin being less soluble in acidulated water and in solutions of certain salts than in pure water, its aqueous solution is precipitated by mineral and certain organic acids, by the chlorides and several other salts of the alkalies, these precipitates being again soluble in water. Tannin renders iodine soluble in water, and prevents the reaction of the latter upon starch; this behavior has been recommended by F. Jean for the estimation of tannin. It yields precipitates with the alkaloids and many so-called neutral principles, with lime-water, most metallic salts, with starch, albumen, and gelatin. The latter precipitate is soluble in solutions of gelatin and of tannin, but insoluble in water and aqueous solutions of certain salts (see GELATINA); this tannate of gelatin is formed in the tanning of hides, and is an important constituent of leather. With solutions of pure ferrous salts no change takes place in the absence of oxygen, but ferric salts give at once in diluted solutions a deep-blue color, and in more concentrated solutions a bluish-black precipitate, with a reduction to ferrous compounds. In the presence of alkalies and in contact with air solutions of tannin rapidly assume a brown color. On the application of heat tannic acid is decomposed, and pyrogallol sublimes at 215°C . (419°F .), leaving metagallic acid behind, which is a black, tasteless substance, insoluble in water, soluble in alkalies, and by heat finally consumed without leaving any residue. The odor adhering to tannic acid may, according to Procter (1864), be removed by benzin, together with some coloring matter.

Composition.—The impossibility of obtaining tannic acid in the crystallized state has rendered the determination of its composition very difficult. A brief review of the widely-differing views held by various chemists will be found under ACIDUM GALLICUM. The latest investigations on the subject appear to furnish conclusive proof that chemically pure tannin must be viewed as an anhydride of gallic acid, and that 1 molecule of it represents 2 molecules of the latter, minus 1 of water. This relation is seen from the following equation: $2(\text{C}_6\text{H}_2(\text{OH})_3\text{COOH})$, gallic acid, $-\text{H}_2\text{O} = (\text{C}_6\text{H}_2(\text{OH})_3\text{COOH})_2\text{O}$, tannin $= (\text{C}_{14}\text{H}_{10}\text{O}_9$, which is the formula of Mulder (1848). The official tannin is contaminated with an odorous principle, some coloring matter, and variable quantities of glucose combined with tannin.

Tannin dissolved in water or in diluted alcohol is gradually converted into gallic acid; occasionally *ellagic acid*, $\text{C}_{14}\text{H}_8\text{O}_9$, is also formed. The latter is insoluble in ether, only sparingly soluble in hot water and alcohol, and in contact with excess of potassa becomes dark-red, and finally black.

Impurities.—Tannic acid should burn from platinum-foil without leaving any residue (mineral impurities), and be completely soluble in 5 parts of alcohol (dextrin insoluble) and the same proportion of warm water (resin insoluble), both solutions being nearly transparent.

Pharmaceutical Uses.—Tannin is employed in the preparation of various proximate principles, such as digitalin.

Off. Prep.—Glycerinum acidi tannici, *Br.*; Trochisci and Unguentum acidi tannici, *U. S.*; Collodium stypticum, *U. S.*

Estimation.—The estimation of tannin and the valuation of the various tanning materials is connected with considerable difficulty, and often requires to be modified according to the nature of other organic compounds present. The following methods may be mentioned:

Precipitation with Gelatin.—This method with a freshly standardized solution of tannin was recommended by Fehling (1853), but, the end-reaction not being readily observed, G. Mueller (1859) recommended the addition of alum to the solution, whereby the gelatin tannate is readily separated. Still better for this purpose, according to F. Schulze (1866), is ammonium chloride, with which the tannin solution is saturated in the cold, and in a saturated solution of which salt the gelatin is dissolved. Schulze's method, according to Buechner (1867), is also applicable in the presence of pectin (1860).

Hammer's method depends upon a similar reaction. Powdered animal skin, obtained by rasping, is soaked in water, then strongly expressed and left in contact with the tannin solution; the amount of tannin is calculated from the difference in specific gravity before and after this treatment.

Precipitation with Alkaloid.—R. Wagner (1866) recommended for this purpose a

standardized solution of cinchonine sulphate acidulated with sulphuric acid and tinged with rose-aniline acetate; the addition is made until the liquid acquires a red color.

Precipitation with Ferric Acetate.—Handtke (1861) employed a titrated solution of this salt, containing also sodium acetate and free acetic acid; the blue-black precipitate settles readily.

Precipitation with Cupric Acetate.—Fleck (1860) precipitated with excess of this salt, and determined the excess of copper volumetrically with potassium cyanide; gallate of copper, being soluble in ammonium carbonate, may thus be removed from the tannate. Wolff (1861) considered incineration of the precipitate as preferable; 1 part CuO obtained corresponds with 1.304 parts of tannin.

Precipitation with Tartar Emetic.—Gerland (1863) recommended a volumetric solution of tartar emetic containing ammonium chloride, whereby the precipitate is readily separated.

Colorimetric Method.—Wildenstein (1863) recommended filtering-paper impregnated with ferric citrate; the amount of tannin is estimated by comparison from the depth of color produced on dipping the paper into the solution.

Estimation by Oxidation.—Titration with potassium permanganate until the production of a permanent red color was recommended by Monier (1858). This method was improved by Loewenthal (1860): a definite quantity of indigo solution is added to the tannin, afterward the volumetric solution of the permanganate; the same quantity of indigo is then oxidized, and by subtraction from the previous result the amount of permanganate used for the oxidation of the tannin is ascertained.

Purification of the Tannin Solution.—The pectin compounds are conveniently removed, according to J. Loewe (1865), by slightly acidulating the infusion or decoction with acetic acid, evaporating, and dissolving the tannin by strong alcohol. Buechner (1867) recommended the repetition of this treatment with the undissolved portion for extracting all the tannin.

Neubauer (1871) showed that animal charcoal in contact with the solution removes completely the tannic and gallic acid, but no pectin; titration before and after this treatment with potassium permanganate gives the amount required for tannic and gallic acids.

Physiological Action.—From experiments upon animals (rabbits) with very large doses, it appears that this acid renders the gastric mucous membrane pale and lustreless and coagulates its mucus. Injected into the blood-vessels, it coagulates the albumen of the blood. To the former of these actions, as well as to its inherent astringency, must be attributed the dryness and sense of constriction which it produces in the mouth and fauces. When administered in moderate doses it causes constipation, at least at first, but the state is not made permanent by a continuance or even an increase of the dose, nor does it seem to derange the digestive function, as a general rule. Occasionally, however, it excites pain in the stomach and bowels, thirst, and eructation, and causes a coated tongue, with tenesmus in defecation. The stools are generally without fecal odor. Tannic acid appears not to be absorbed, and not to circulate as such, but to be converted into gallic acid. In this form alone is it found in the blood and urine. Indeed, it could not remain in the blood without coagulating it, as experiments on animals demonstrate. But as gallic acid is not an astringent, and as one of the best uses of tannic acid is to control internal hæmorrhages, it is difficult, while admitting the conversion of the one acid into the other, to explain the therapeutic operation of the latter in the affections named. Several theories have been proposed for this purpose, but all of them are unsatisfactory. Lewin has shown that the coagula of albuminous substances formed by tannic acid are soluble in an excess of albumen, and tannic acid, if made slightly neutral, loses its coagulating power. Thus, an albuminate of tannin formed in the blood is dissolved again in an excess of that alkaline liquid. A small portion of tannin escapes neutralization, and is discharged with the urine unchanged; and hence, according to Lewin, tannin, as such, may exert its power in all parts of the system. It would appear also that the hæmostatic and analogous qualities of tannic acid are due, not to an action upon the blood, but upon the blood-vessels, by which they become constricted and the flow of the blood through them is checked.

Medical Uses.—The astringent property of this substance renders it useful in relaxed states of the gastro-intestinal mucous membrane, such as exist in certain forms of *dyspepsia* (with excessive acid, mucous, or watery secretion, or with flatulence), but still more in chronic *diarrhœa*, *dysentery*, *lientery*, etc. The presence of fever usually contraindicates it. It is less used, although hardly less efficient, in chronic fluxes of other organs, which it can influence only through the blood, as *chronic bronchitis*, *whooping cough*, and *phthisis*. It often moderates, or even suspends, the *night-sweats* of the

last-named disease and those of other heetical states. But it is in *hæmorrhages* that tannic acid especially shows its power. Employed originally to restrain *menorrhagia*, it was afterward used successfully in other forms of uterine hæmorrhage, including those produced by organic diseases of the womb. The more passive forms are the most improved by it. In *hæmaturia*, even of organic origin, in passive hæmorrhage from the *stomach* and *bowels*, in some cases of *hæmoptysis*, and also of *hæmophilia*, it has displayed remarkable efficacy. In hæmoptysis it is best employed in an atomized solution. Not only in forms of *albuminuria* with copious urination, but in those in which the secretion is scanty, or perhaps chiefly in these, it is said to have been useful. Hiller, who tested the tannate of sodium in these cases, found it to be quite unavailing to lessen the albuminuria (*Zeitsch. klin. Med.*, vi. 489).

It is very efficient as a direct or local hæmostatic when finely powdered and applied to a bleeding part. It is neither painful nor irritating. It is, therefore, a convenient application in *hæmorrhage* from the nose, vagina, or rectum, from leech-bites, varicose veins, etc. Its constringing operation is of great value in producing the contraction of various soft tissues.* A concentrated solution, made with an ounce of fresh tannin and 6 drachms of water, has a syrupy consistence, and is preferable to tannin itself for many topical applications. It is adapted to the treatment of wounds, ulcers, and mucous surfaces. A solution of tannic acid in tincture of benzoin (1 part to 4) tends to repress the development of *variolous* pustules. A powder made with 1 grain of tannin and 30 grains of orris- or marshmallow-root has been used as a snuff to arrest acute *coryza* in its forming stage; and an ointment containing 1 grain of tannin and 2 drachms of simple ointment has been applied to the nostrils, on a roll of soft linen or paper, for the same purpose in infants. Powdered tannin may be used as a snuff in chronic *coryza*, and in the treatment of nasal *polypi* a 10 per cent. solution in water has also been used. A watery solution is a useful application to sore *nipples*, and an ointment of tannin, or suppositories containing it, is a useful palliative in *anal fissure*, *hæmorrhoids*, and *prolapsus ani*. A solution of from 15 to 60 grains of tannin in about 4 fluidounces of water, injected into the bladder, has sometimes cured obstinate *vesical catarrh*. Aphthous *ulcers of the mouth*, *mercurial salivation*, *spongy gums*, and a relaxed condition of the mucous membrane of the *pharynx*, are all benefited by this astringent. Introduced into a carious cavity, it often allays *toothache*. In *coryza* and the other forms of chronic mucous inflammation mentioned the glycerite of tannin has been employed, but it is probably less efficient than the watery solution. Injections of a solution of tannic acid have been successfully used in *gleet* and *leucorrhæa*; in the latter disease they are very useful, but less so than the more prolonged application of tampons or sponges saturated with the solution. Tannic acid hip-baths have been recommended as more eligible than these injections, etc. The latter method often cures *prolapsus of the uterus* due to relaxation of the vagina. Chronic inflammations of the *conjunctiva*, especially the granular form, and *pannus*, have been successfully treated with very finely-powdered tannin; and injections of a solution of this substance into vascular *erectile tumors* have been followed by their permanent contraction. A dentifrice containing tannin and charcoal in equal proportions is very efficient in removing the discoloration of the *teeth* produced by preparations of iron.

The *dose* of tannic acid is from 3 to 10 grains (Gm. 0.20–0.60). It is best administered in pill, except in cases of hæmorrhage, when it should be given dissolved in water sweetened and flavored. Lewin recommends, in order to lessen the tendency of tannic acid to disorder the digestive organs, that it be given as follows: $\mathcal{R}$. Solut. of tannic acid in water (2 per cent.) f3v; the white of one egg. Incorporate by shaking. The energy of this mixture appears to be very slight if a prompt astringent action is desired; it may be useful in the few cases which call for a continuous administration of the medicine. Externally, tannic acid is employed in a watery solution containing from 3 to 10 grains to the ounce (Gm. 0.20–0.60 to Gm. 30). Its incorporation in an ointment or with glycerin impairs its astringent action.

ACIDUM TARTARICUM, U. S., Br., P. G.—TARTARIC ACID.

Sal essentielle tartari.—*Acide tartrique*, *Acide du tartre*, Fr.; *Weinsäure*, *Weinsteinsäure*, G.
Formula $\text{H}_2\text{C}_4\text{H}_4\text{O}_6 = (\text{CHOH})_2(\text{COOH})_2$. Molecular weight 150.

* *Styptic colloid*, which consists of a saturated solution of tannin in alcohol, to which ether and then gum-cotton are added to saturation, when applied to a part rapidly condenses and grows firm, so as to arrest the discharge of blood, serum, or pus. It is also used after the surfaces of wounds, fractures, etc. have been coaptated, to keep their edges from being displaced.

Origin.—It is met with either free or in combination with bases in grapes, sumach-berries, tamarinds, pineapples, and other acidulous fruits; also in other parts of many plants. It was first isolated by Scheele (1769), and by Retzius (1770) obtained in crystals.

Preparation.—The British Pharmacopœia gives the following directions: Take of Acid Tartrate of Potassium 45 ounces; Distilled Water a sufficiency; Prepared Chalk 12½ ounces; Chloride of Calcium 13½ ounces; Sulphuric Acid 13 fluidounces. Boil the acid tartrate of potassium with 2 gallons of the water, and add gradually the chalk, constantly stirring. When the effervescence has ceased add the chloride of calcium dissolved in 2 pints of the water. When the tartrate of calcium has subsided pour off the liquid and wash the tartrate with distilled water until it is rendered tasteless. Pour the sulphuric acid, first diluted with 3 pints of the water, on the tartrate of calcium, mix thoroughly, boil for half an hour with repeated stirring, and filter through calico. Evaporate the filtrate at a gentle heat until it acquires the specific gravity 1.21, allow it to cool, and then separate and reject the crystals of sulphate of calcium which have formed. Again evaporate the clear liquor till a film forms on its surface, and allow it to cool and crystallize. Lastly, purify the crystals by solution, filtration if necessary, and recrystallization.

This process is the one which in its main features is followed in preparing tartaric acid on the large scale. An excess of sulphuric acid is necessary for the decomposition of the tartrate of calcium to ensure the complete removal of the calcium, since tartaric acid does not crystallize properly from a solution of acid tartrate of calcium. Boiling the precipitate with the sulphuric acid is avoided, and digestion for 2 or 3 days substituted. After concentration in the vacuum-pan the liquid is heated with wood charcoal or pure animal charcoal to remove coloring matter, filtered, and crystallized. The last crystallizations are more or less colored, and, like the mother-liquor, are purified by digestion with wood charcoal. Should the free sulphuric acid accumulate in the mother-liquor, its partial removal with milk of lime will be necessary. Where chloride of calcium cannot be used as a waste product for the decomposition of the tartrate of potassium the cheaper sulphate of calcium is used for the purpose.

The rationale of this process is as follows: Acid tartrate of potassium yields with calcium carbonate insoluble calcium tartrate and soluble potassium tartrate. The solution of the latter reacts with the calcium chloride or sulphate, furnishing an additional quantity of insoluble calcium tartrate and soluble potassium chloride or sulphate, which is removed by washing. The calcium tartrate, when digested with sulphuric acid, yields sparingly soluble sulphate of calcium, which precipitates, and tartaric acid, which, being freely soluble in water, remains in solution and is recovered by crystallization. Large clear and colorless crystals are best obtained in the presence of a minute quantity of free sulphuric acid.

A process was patented by Goldenberg in 1878, according to which 226 parts of normal potassium tartrate, dissolved in 1800 parts of water, are mixed with 112 parts of burned lime previously slaked with 16 parts of water; the decomposition is effected at ordinary temperatures, the greater part of the calcium tartrate being deposited as a powder, from which the potassa solution is easily filtered; the filtrate retains calcium tartrate, which on boiling is separated in flocks.

The decomposition of argols by lime is effected by heat, when the nitrogenous principles present are decomposed, with the evolution of ammonia, and the calcium tartrate is separated in a gelatinous form, changing, however, to finely pulverulent on neutralizing the alkaline liquid with hydrochloric or sulphuric acid. The brown calcium tartrate is collected on a filter, washed, expressed, and decomposed by sulphuric acid, and the solution of tartaric acid treated with boneblack, or once more converted into the calcium salt by boiling with lime and chalk, whereby a much lighter colored precipitate is obtained.

Tartaric acid is now largely manufactured in the United States; in 1867 over 212,000 pounds were imported; in 1882, only 8 pounds.

Properties.—Tartaric acid crystallizes in colorless, oblique, rhombic prisms or tables, which are inodorous and have a strongly acid but agreeable taste. They have the specific gravity 1.764, dissolve at 17° C. (62.6° F.) in 0.6 parts of water, 2 parts of 85 per cent. alcohol, 3.6 parts of absolute alcohol, 23 parts of ether, and 250 parts of absolute ether; are more freely soluble in the same liquids at the boiling temperature, and are likewise soluble in methylic alcohol and in glycerin, but insoluble in chloroform and benzin.

We found (1863) the density of aqueous solutions of tartaric acid at 16° C. (60.8° F.) to be as follows:

Tartaric acid, per cent.	Specific gravity.	Tartaric acid, per cent.	Specific gravity.	Tartaric acid, per cent.	Specific gravity.	Tartaric acid, per cent.	Specific gravity.
1.00	1.0044	15.00	1.071	30.00	1.153	45.00	1.240
2.50	1.0114	17.50	1.083	32.50	1.167	47.50	1.255
5.00	1.023	20.00	1.097	35.00	1.181	50.00	1.271
7.50	1.035	22.50	1.111	37.50	1.195	52.50	1.287
10.00	1.047	25.00	1.125	40.00	1.209	55.00	1.304
12.50	1.059	27.50	1.139	42.50	1.224	57.50	1.325

The crystals contain no water of crystallization, are not deliquescent in the air, and may be heated to 135° C. (275° F.) without losing weight (see below), but they melt, and on heating the mass to about 200° C. (392° F.) it is decomposed, with disengagement of water, carbon dioxide, acetic acid, and other compounds, gives off the odor of burning sugar, and leaves a charcoal which ultimately burns without leaving any residue. In American commerce tartaric acid is usually found in the state of powder. The aqueous solutions of tartaric acid and of its salts deviate the plane of polarized light to the right; hence the name of *dextrotartaric acid*. Some grapes appear to contain naturally an acid isomeric with the foregoing, which is called *racemic*, *wic*, or *paratartaric acid*. The same acid is obtained by heating for several days in closed vessels tartaric acid with about 15 per cent. of water to 175° C. (347° F.); its solutions do not affect polarized light, but some of its salts crystallize in two distinct hemihedric forms, one of which con-

FIG. 9.

Crystal of Tartaric Acid.

tains the ordinary or dextrotartaric acid, while the other contains *levotartaric acid*, another isomeric form, turning the plane of polarized light to the left. When dextrotartrate of cinchonine is heated to 170° C. (338° F.), it is converted into paratartrate, but at the same time a fourth isomeric modification is obtained, the calcium salt of which crystallizes after the calcium paratartrate. This new acid is *meso-* (or *inactive*) *tartaric acid*, so called because its solutions have no effect upon polarized light, and the acid cannot be resolved into dextro- and levotartaric acids under the same circumstances as racemic acid. Finally, a fifth isomeric acid may be obtained from tartaric acid by fusion, which occurs between 170° and 180° C. (338° and 356° F.), when without loss in weight *metatartaric acid* is formed, whose solution has the same influence upon polarized light as that of the acid from which it was made; but it is deliquescent, and its salts dissolve more freely in water and crystallize in forms different from the dextrotartrates. L. Pasteur was engaged during the years 1847 to 1853 in investigating most of these facts. These isomeric compounds are, however, little known.

Tartaric acid is a strong bibasic acid, forming normal and acid salts, most of which are readily obtained in crystals; all are blackened by heat, and evolve an odor similar to that of burning sugar.

The normal tartrates, with the exception of those with an alkaline base, are nearly all insoluble or slightly soluble in water, but dissolve in diluted nitric acid. Calcium tartrate is almost insoluble in water, but dissolves in chloride of ammonium, acetic acid, and cold potassa solution, being precipitated from the latter on boiling. Tartaric acid, added to the concentrated solution of a potassium salt, produces a precipitate of acid tartrate of potassium; a similar precipitate, which is rather more soluble in water, is produced with ammonium salts; the same precipitates are obtained with solutions of acid tartrates or with neutral tartrates dissolved in diluted hydrochloric acid.

Impurities.—Tartaric acid, heated upon platinum-foil, should be consumed without leaving more than a trace of ash (mineral impurities). It should completely dissolve in 3 parts of alcohol (saline impurities). Its solution in 10 parts of water is not precipitated or colored dark by hydrosulphuric acid (lead, copper, etc.), and is not precipitated by chloride of barium (sulphuric acid), by sulphate of calcium (oxalic or racemic acid) or by oxalate of ammonium (calcium salts). 1.50 Gm. of tartaric acid dissolved in alcohol, and the solution mixed with half its bulk of water and of concentrated solution of potassium tartrate, yields a precipitate of potassium bitartrate, which, after washing with diluted alcohol and drying, weighs 1.88 Gm. A mixture of solutions of 1 part each of tartaric acid and of potassium acetate, in 3 parts of cold water, on being mixed with an equal bulk of alcohol, yields a precipitate which, if collected after 2 hours and washed and dried as stated before, should weigh between 1.25 and 1.26 parts (U. S.). A solution

of 0.75 Gm. of tartaric acid requires for exact neutralization 10 Ccm. of the volumetric solution of soda, or 75 grains of the former need 1000 grain-measures of the latter (*Br.*).

Off. Prep.—*Ferri et ammonii tartras*, *Pulvis effervescens compositus*, *U. S.*; *Sodæ citro-tartras effervescens*, *Br.*

Physiological Action.—Given to dogs in large and concentrated doses, it acts poisonously, quickening the pulse and respiration, and causing debility, spasm, paralysis, and death, after which the blood remains liquid, but the stomach is not inflamed. It is in part excreted unchanged with the urine. It has been given to cats in large doses without striking consequences. In man, an ounce of tartaric acid dissolved in half a pint of warm water is said to have acted like a corrosive poison, causing violent burning pain in the throat and stomach, followed by obstinate vomiting, and death at the end of 9 days. Nearly the whole of the alimentary canal was found highly inflamed. But in another case 6 drachms of the acid were taken within 24 hours without the least inconvenience. The alleged poisonous action in the first case is therefore open to doubt.

Medical Uses.—Tartaric acid is hardly ever prescribed in medicine alone, but generally in combination with alkalis or their carbonates or with carbonate of magnesium. It may be used to prepare whey, which is thought to be febrifuge and diuretic, and it is said to modify the unpleasant taste of the liquid preparations of cinchona, senna, and rhubarb. Associated with sugar, mucilage, and some flavoring extract, it serves to moisten the throat in *pharyngitis and pulmonary catarrh*; and it is even alleged to be capable of dissolving the false membranes of *diphtheria* (*Med. News and Abstract*, Sept. 1881, p. 536). It is said to correct the *fetor of the feet* to which some persons are subject when it is strewn as a dry powder in the stockings. Dose, 10 to 30 grains (Gm. 0.50–2.00).

ACIDUM VALERIANICUM.—VALERIANIC ACID.

Acidum valericum.—*Acide valériannique*, *Acide valérique*, Fr.; *Baldriansäure*, *Valeriansäure*, G.

Formula $\text{HC}_5\text{H}_9\text{O}_2 = (\text{CH}_3)_2\text{CH}.\text{CH}_2.\text{COOH}$. Molecular weight 102.

Origin and Formation.—Valerianic acid has received its name from valerian-root, from which it was obtained and recognized as a distinct acid by Grote (1830); it has been found in the flowers of *Anthemis nobilis*, in wormwood, angelica-root, etc., and in dolphin oil, obtained from *Delphinus globiceps*, *Cuvier*, by Chevreul (1817), who named it *delphinic acid*; it is found among the products of oxidation of a large number of organic substances, and is prepared for medicinal purposes almost exclusively by oxidizing amyl alcohol with bichromate of potassium and sulphuric acid, a process recommended by Balard (1845).

Preparation.—Valerian-root is distilled with water, the oil is removed from the acid distillate, the latter neutralized with soda, and evaporated to dryness. 5 parts of this residue are, according to Wittstein (1845), dissolved in 5 parts of water, and distilled with 4 parts of sulphuric acid diluted with 8 parts of water. The oily portion of the distillate is purified by fractional distillation. The yield is increased if bichromate of potassium and sulphuric acid are added to the water distilled with the root (Lefort, 1846).

In the preparation of valerianic acid from fusel oil valerianate of sodium is prepared as the first step (for details see *SODII VALERIANAS*), and this is then distilled with sulphuric acid. To obtain a concentrated acid B. J. Crew (1860) manipulates as follows: 8 parts of sodium valerianate and 3 parts of water are mixed, and $3\frac{1}{2}$ parts of sulphuric acid gradually added to the mixture. Sulphate of sodium is formed, and the liberated valerianic acid rises as an oily layer to the surface. The latter is separated, and repeatedly agitated with small portions of oil of vitriol to deprive it of water, which cannot be separated by distillation. When the specific gravity of the oily layer has been reduced to below 0.950, it is distilled, and that portion of the distillate having the specific gravity 0.940 or more is collected by itself, to be dehydrated by sulphuric acid as before. The remaining portion of the distillate, rather more than half the quantity of the whole, will have the required specific gravity, 0.935. The weaker but heavier acid comes over first, and may be readily brought to the specific gravity 0.945 by oil of vitriol, when it is again ready for fractional distillation (F. C. Musgiller, 1868).

Properties.—Valerianic acid is a colorless, thin, oily liquid, of a disagreeable odor resembling that of valerian and of old cheese, and has a sour, acid, unpleasant taste, producing upon the lips and tongue the sensation of burning; diluted with water, the taste is less disagreeable, with a sweet after-taste. When heated, valerianic acid evaporates

without residue, and ignited burns with a luminous flame. It is soluble at 15° C. in 30 parts of water, and by agitation with a small quantity of that liquid takes up about 20 per cent. of its weight, without losing its oily consistence. It dissolves in all proportions in alcohol, ether, chloroform, carbon bisulphide, and volatile oils, the hydrated acid, however, producing a turbid mixture with the last-named liquids. The specific gravity is 0.935, which increases if the acid becomes more hydrated; its boiling-point is 175° C. (347° F.). Musgiller ascertained that an acid of 0.933 specific gravity boils between 177.2° and 178.9° C. (351° and 354° F.); if of greater density the boiling-point is lower. The hydrate, $C_5H_{10}O_2 \cdot H_2O$, has the density 0.945, and requires only 25 parts of cold water for solution.

The composition of valerianic acid, $C_5H_{10}O_2$, bears to amylic alcohol, $C_5H_{12}O$, the same relation as acetic acid does to ordinary alcohol. (See ACETUM.) Hydrogen being eliminated from the alcohol in the form of water under the influence of oxidizing agents, the remaining molecule is oxidized to the acid; $C_5H_{12}O + O_2$ yields $HC_5H_9O_2 + H_2O$. The officinal acid is *isopropylacetic acid*. Three other acids of the same ultimate composition may be prepared, which, however, differ from the preceding in their specific gravities, boiling-points, behavior to polarized light, and the solubility in water of their barium and silver salts.

The normal salts of valerianic acid, when perfectly dry, are inodorous; in the presence of moisture, and still more in contact with carbonic acid, they have the odor of the acid; their taste is decidedly sweet. Most of the salts are soluble in water, several dissolve also in alcohol; from these solutions valerianic acid is liberated by nearly all the mineral and organic acids, even by acetic acid.

Impurities.—The solubility of valerianic acid, in not less than twenty-six and not over thirty times its weight of water, affords a ready means of discovering the presence of certain impurities. Alcohol decreases, and water, acetic acid, and butyric acid increase, the density of valerianic acid, and render it more soluble in water, while it becomes less soluble and of less density through the presence of amylic alcohol, amylic aldehyd, amyl valerianate, and fixed oils. On adding ammonia-water slightly in excess to valerianic acid a clear solution should be produced; this is turbid or separates an oily layer in the presence of one or more of the four compounds last mentioned. Butyric acid, if present, will, according to Laroque and Huraut, produce with concentrated solution of acetate of copper pale-blue scales of copper butyrate, while pure valerianic acid mixed with the same solution yields a mixture which is transparent for several minutes, then separates oily drops of copper valerianate, which are gradually converted into a greenish-blue crystalline powder. Acetic acid is readily detected by neutralizing the acid with ammonia and adding to the cold clear liquid a slight excess of diluted ferric chloride or subsulphate, when ferric valerianate will be precipitated and ferric acetate form a deep brown-red solution. Admixtures of hydrochloric or sulphuric acid are detected in the aqueous solution of valerianic acid, after adding a little nitric acid, by the nitrates of silver and of barium.

Off. Prep.—Ammonii valerianas, Quinæ valerianas, *U. S.*

Physiological Action and Medical Uses.—According to Reissner's experiments on animals, it coagulates albumen, blood-serum, and milk, and is slightly irritating to the integuments. Its odor is not imparted to the urine or the blood, but may be perceived in the peritoneal cavity. It quickens but weakens the heart's action and the respiration, produces debility and then paralysis of the limbs, and spasms before death; after which, if it takes place rapidly, the gastric mucous membrane is pale, but if slowly this membrane and that of the intestine are inflamed, the kidneys congested, and the urine is turbid and bloody. The acid is not used in medicine except in combination, but it is very doubtful if it gives any special properties to the bases with which it is associated, unless it does so in valerianate of ammonium.

ACONITIA, Br.—ACONTINE.

Aconitina, Aconitinum.—Aconitine, Fr.; Aconitin, G.

Formula $C_{35}H_{43}NO_{12}$. Molecular weight 645.

Preparation.—The outlines of the process recognized by the British Pharmacopœia are as follows: Coarsely-powdered aconite-root is exhausted with alcohol by heating to ebullition, then cooling, and finally percolating; the tincture is completely freed from alcohol by distillation and evaporation; the extract is mixed with twice its weight of boiling distilled water; the mixture allowed to cool and filtered; the filtrate is precipitated by ammonia in slight excess, and the mixture heated gently over a water-bath, whereby the

precipitate forms a mass which is readily separated by a filter, and after drying reduced to a coarse powder, which is exhausted with pure ether; the ethereal liquid is distilled, the impure alkaloid dissolved in warm distilled water acidulated with sulphuric acid, and when the solution is cold ammonia diluted with four times its bulk of distilled water is cautiously added; the precipitate is collected on a filter, washed with a small quantity of distilled water, and dried by slight pressure between folds of filtering-paper.

The process proposed by Prof. Procter (1861) as a modification of that previously suggested by Headland was adopted by the U. S. Pharmacopœia previous to 1880, and is as follows: The tincture obtained by digesting and displacing powdered aconite-root with alcohol is concentrated by distillation to one-third of the weight of the root; the liquid is mixed with an equal bulk of water acidulated with sulphuric acid; oil and resin which separate are removed; the remaining liquid, containing aconitine sulphate, is concentrated to a small bulk, and agitated with ether to remove more of the oil and impurities; a slight excess of ammonia is added to liberate the alkaloid, which is exhausted by agitation with ether; lastly, the ether is evaporated spontaneously and the dry residue powdered.

Neither of these processes yields *pure* aconitine, the product being always amorphous and of variable composition. Duquesnel (1872) showed that the use of mineral acids in the preparation of aconitine causes the production of amorphous alkaloids, while aconitine is not decomposed by tartaric acid; his process, modified by Wright (1876, 1880), is as follows: Powdered aconite-root is exhausted with alcohol containing 0.5 per cent. of tartaric acid: the alcohol is distilled and evaporated at a low temperature or *in vacuo*; the extract is diluted with its own bulk of water, filtered from the oil and resin, agitated with ether or petroleum naphtha, whereby more resin is removed, and then precipitated by excess of potassium carbonate; the alkaline liquid retains the amorphous bases in solution, while the washed precipitate, after dissolving in ether, mixing this solution with petroleum naphtha, and evaporating, yields crystallized aconitine, which still retains a small proportion of the amorphous alkaloids, from which it can be completely freed only by a tedious and very wasteful process.

Hottot and Liégeois's process (1864), which has been largely followed in France, differs from the preceding one mainly in the substitution of sulphuric for tartaric acid, and in the precipitation of the alkaloids by magnesia.

According to Wright (1876), the amount of pure aconitine obtainable from aconite-root is .03, or possibly .04, per cent., being about one-third of the total yield of alkaloid (Groves).

Properties.—Aconitine, as obtained by the process of the British Pharmacopœia, is a white, usually amorphous solid, soluble in 150 parts of cold and 50 of hot water, and much more soluble in alcohol and in ether; it is strongly alkaline to reddened litmus, neutralizing acids and precipitated from them by the caustic alkalies, but not by carbonate of ammonium or the bicarbonates of sodium or potassium. It melts with heat and burns with a smoky flame, leaving no residue when burned with free access of air. When rubbed on the skin it causes a tingling sensation, followed by prolonged numbness. Aconitine is colored orange-yellow by sulphuric acid, changing to brown and colorless; its solution in diluted phosphoric acid, carefully evaporated, becomes violet-colored; mixed with sugar, aconitine becomes rose-red with sulphuric acid. As seen in commerce, aconitine is always a mixture of several alkaloids. (See ACONITUM, p. 115.)

From his researches reported to the British Pharmaceutical Conference (1866 to 1874) Mr. T. B. Groves concluded that pure aconitine occurs in two modifications, a crystalline and an amorphous, both of which, when precipitated with ammonia and heated to boiling, do not fuse, but become quite brittle. Amorphous aconitine dissolves in 1000 parts, crystallized nitrate of aconitine in 520 parts, of water containing 1½ per cent. of ammonia; the latter solution gradually heated becomes turbid, and when near the boiling-point separates microscopic crystals of aconitine, while the ammoniacal solution containing the amorphous alkaloid becomes clear again near the boiling-point of the liquid. The ammoniacal solutions of both modifications speedily decompose, the amorphous aconitine being somewhat more stable. Pure aconitine gives no characteristic color-reactions with acids or oxidizing agents. Its nitrate crystallizes readily from neutral solutions (Groves).

These investigations were continued by C. R. Alder Wright (1875 to 1880), who found the physiologically active and crystallizable aconitine to have the composition above given, and when heated with water to 140° or 150° C. (284° or 302° F.), or saponified with an alkali, to be decomposed into benzoic acid (18.92 per cent.), and amorphous *aconine*, $C_{36}H_{39}NO_{11}$, which is bitter, not acid, almost insoluble in ether, dissolves readily in water, alcohol, and chloroform, and is identical with acolyctine and napelline. On heating aconi-

tine to 100° C. with strong solution of tartaric acid, it yields *apoaconitine* $C_{33}H_{41}NO_{11}$, which crystallizes from ether and melts at 185° C. Both derivatives may be present in commercial aconitine. These and the other amorphous bases are with great difficulty removed by repeated crystallization from ether or ether and petroleum naphtha, and are best eliminated by crystallization as nitrate or hydrobromate. The pure alkaloid has an acrid and faintly bitter taste, is nearly insoluble in water and benzine, but dissolves readily in chloroform, benzol, ether, and alcohol, and melts in a capillary tube at 183° to 184° C., the melting-point being lowered and the color more darkened by the presence of amorphous bases; on being dissolved in ether, and the solvent allowed to evaporate spontaneously, the last drop of it should dry up to crystals; the acid obtained on saponification, on being fused at 250° C. with potassa, the mass treated with hydrochloric acid and ether, and the ethereal solution evaporated, should not give a green color to ferrie chloride (absence of pseudaconitine). The figures, ascertained by elementary analysis, are the only reliable means of distinguishing aconitine from japaconitine.

Pseudaconitine, $C_{33}H_{41}NO_{12}$ (see p. 115), which has been sometimes sold for aconitine, closely resembles the latter base in appearance and behavior, but may be distinguished from it by requiring about 230 parts of chloroform, 100 parts of boiling ether, and 1500 to 2600 parts of diluted ammonia of $1\frac{1}{4}$ per cent. strength for solution; by its lower melting-point (104° to 105° C.); and by yielding on saponification with alcoholic potassa 26.49 per cent. of veratric acid. Its nitrate crystallizes only from strongly acid solutions (Groves).

Liégeois and Hottot found that aconitine precipitated by ammonia from cold solutions contains 25 per cent. of water, which is given off at 85° C. (185° F.), and Hager (1875) has directed attention to this as a source of the variable strength of commercial aconitine. According to Wright, however, the process adopted for its preparation is evidently of primary importance.

That commercial aconitine varies greatly in strength has been repeatedly observed. Dr. Squibb (*Ephemeris*, i. 135) suggests that no aconitine should be accepted which will not give within 15 minutes a distinct aconite sensation, not amounting to tingling, but very suggestive of it, from $\frac{1}{800}$ of a grain (.0008 Gm.) diluted to the measure of 1 fluidrachm (3.7 Ccm.), after holding the solution for 1 minute in the anterior part of the previously well-rinsed mouth. Tested in this manner, he found 1 grain of good aconite-root to be represented by 1, $\frac{4}{8}$, $\frac{1}{83}$ (Merck's pseudaconitine), and $\frac{1}{111}$ (Duquesnel's crystallized aconitine) grain of different commercial samples of aconitine. The last-named sample (Duquesnel's) was ascertained (*Ephemeris*, i. 167) to be a nitrate containing not more than 80.7 per cent. of the hydrated alkaloid.

Off. Prep.—Unguentum aconitiæ, Br.

Physiological Action.—When applied to the sound skin in an ointment or in alcoholic solution it produces itching and prickling, followed by anæsthesia of the part, without redness or heat. In contact with the derm it causes an intense and prolonged burning, and it violently irritates the conjunctiva. Its local action on the tongue, fauces, and stomach produces burning and tingling sensations. Several experimenters have thrown doubt upon the identity in action of aconite and aconitine, some expressing their views of the differences between them by saying that the former is acro-narcotic and the latter narcotic. The acro-narcotic principle, sometimes called napellina, appears to be feebler than aconitine, but to resemble it in all respects except that it does not poison the heart of batrachians (Murray). In regard to the action of aconitine experimenters are not agreed. Some maintain that it paralyzes the central nervous system; others, that it paralyzes the peripheral motor nerves; still others, that it affects simultaneously the cerebral nervous system and the muscles, paralyzing both; and, finally, it is held to act essentially on the centres of the medulla oblongata and spinal cord proper, first exciting and then paralyzing them. The centres of voluntary movement are affected before the sensory centres become involved. The order in which the different organs are paralyzed is said to be the sensory, and then the motor nerves, the sympathetic nerve, and finally the muscles. The respiratory apparatus and the heart are affected through the nervous system, and death is due to a suspension of the respiration caused by the action of the poison upon the medulla oblongata. These results have been substantiated by Mackenzie. They also agree essentially with those of Harley, the most interesting and lucid of all. His experiments were performed on the horse, dog, cat, and on man. Their results in the lower animals were, summarily, these: Paralysis of the external muscles of respiration which dilate the chest; intermittent spasm of the muscles attached to the upper part of the chest and of those of the respiratory passages: incomplete paralysis of the diaphragm;

increased frequency of the heart-beat proportioned to the impediment to the circulation; persistence of the heart-beat after respiratory death; spasm of the pharynx and œsophagus; and general debility, but no muscular paralysis. These conclusions have been confirmed by Ringer (1880). On dissection the lungs are collapsed and pale; the heart retains its irritability for some time; its left cavities are empty and contracted; and the right side, as well as the large veins leading to it, is distended with dark blood.

Fothergill's experiments on rabbits, guinea-pigs, and cats show that a lethal dose of aconitine ceases to be so if the animals have had an appropriate dose of digitalin from 5 to 9 hours previously. In like manner, the lethal effects of aconitine are prevented by atropia and also by strychnia: "while aconitine kills by paralyzing the respiration, atropine and strychnia, which act very powerfully on the respiratory centres, are potent to prevent death." According to Oulmont, aconitine displays physiological and therapeutical action in the dose of a quarter of a milligram (gr. $\frac{1}{250}$), but may be gradually increased to 1 and even 2 milligrams (gr. $\frac{1}{80}$ to $\frac{1}{40}$) a day without injury.

The action of aconitine upon man is illustrated by Harley's observations. One-two-hundredth of a grain of aconitine taken internally caused slight tingling in the mouth and face, lasting for several hours. The one-hundred-and-fiftieth of a grain occasioned also a sense of glowing and numbness and a tendency to sleep. One-fiftieth of a grain produced the following effects: languor, giddiness, sleepiness, hazy vision, nausea in the erect posture, dysphagia, pain in the back of the neck and behind the jaws, a glowing, tingling feeling over the whole body, and burning heat in the gullet. The sense of muscular weakness is comparable to that induced by conium. To these symptoms may be added colic, spasmodic vomiting, and dysphagia; in some cases darting pains in the branches of the fifth nerve; dilatation of the pupils; acceleration, followed by progressive irregularity and debility, of the heart, and a corresponding infrequency of the respiratory movements and lowering of the temperature. In fatal cases the pulse is small, weak, and, above all, irregular; the rate and rhythm of the respiratory movements are similarly affected; the skin is cold and clammy, the pupils contracted; vision is impaired; there is a burning pain in the mouth, extending along the gullet, a swollen tongue, dysphagia, and great præcordial anxiety; vomiting usually occurs and convulsions, and consciousness is more or less impaired. Post-mortem examination shows hyperæmia of the stomach and small intestines, and the viscera generally are charged with blood. Cases of fatal poisoning by aconitine are very rare (Stevenson, *Guy's H. R.*, xli. 307; Laborde et Duquesnel, *Des Aconits et de l'Aconitine*, 1883). Napelline appears to be identical with aconitine in the nature of its effects, but their intensity is "incomparably less" than those of crystallized aconitine.

Medical Uses.—The internal employment of this alkaloid ought rarely to be resorted to, on account of its dangerous activity as a poison. Aconitine has been administered in febrile diseases for the same reason that aconite and other sedatives of the heart have been employed, and the result has been that, although the medicine lessened the frequency of the pulse, it exerted no appreciable influence upon the course or issue of the disease. Such was a result of Harley's use of the medicine in *scarlet* and *typhus fevers*, although it appeared to him that in typhus treated by this medicine the crisis occurred early. It has also been administered advantageously for the cure of *neuralgia* in the dose of $\frac{1}{125}$ gr. (Gm. 0.0005), and probably in neuralgia of the fifth pair there is no remedy more efficient. It is said to have arrested the paroxysms in cases which had resisted all other remedies. The cure of some extremely aggravated cases of facial neuralgia has been accomplished by doses of aconitine, beginning with $\frac{1}{125}$ gr. (Gm. 0.0004), and gradually increased to $\frac{1}{95}$ gr. (Gm. 0.007), three times a day (*c. g.* Weir, *Philad. Med. Times*, x. 48). But it is chiefly in recent cases produced by cold that its efficacy is displayed. According to Oulmont and Gubler, the pain and fever of acute articular *rheumatism* are rapidly reduced by aconitine given daily to the amount of $\frac{1}{125}$ gr. (Gm. 0.0005). The efficacy of the medicine is not, however, accepted as proven, and its dangerous qualities should deter from its unnecessary use, which we hold the treatment of rheumatism by its means to be. Owing to the varying degrees of strength of the alkaloid as found in the shops, the primary dose should not exceed gr. $\frac{1}{250}$. It may be repeated two or three times a day, and given less or more frequently and in smaller or larger doses, according to its effects. Its efficiency is, however, much greater in the form of an ointment, which may contain 2, or from that to 5, grains in a drachm of lard (Gm. 0.13–0.30 in Gm. 4), or in the form of a solution made by dissolving 1 grain of aconitine in 2 fluidrachms (Gm. 0.06 in Gm. 8.00) of alcohol. Its mixture or solution is facilitated by chloroform. Either preparation should be applied with a soft brush or with the finger protected by a glove. Gubler has used the medicine hypodermically in the dose of gr. $\frac{1}{128}$ twice a day.

Origin.—The plant, which attains a height of 3 to 4 feet (.9 to 1.2 M.) and is very variable in appearance, as indicated by one of its specific names, is met with throughout the greater portion of Asia and Europe, mostly in mountainous regions. It grows in the Himalaya Mountains at an altitude of from 10,000 to 16,000 feet, and from there north and west in Siberia, and in Europe south to the Alps and Pyrenees. It is frequently cultivated for ornament and for medicinal use, but Schrott (1853) found the cultivated plant far less active than the one grown wild. The poisonous properties of this and allied species have been known in ancient times, and the Greek name, *akoniton*, was most likely applied to these plants. Aconite was introduced into medicine by Stoerck (1762).

Description.—1. ACONITE-ROOT. The subterraneous portion of the plant consists of a tuber, which is contracted below into a conical root; from a lateral bud of the tuber a short rhizome is produced, developing at its end again into a tuber, bearing a bud at its top from which the stem for the succeeding year will be produced. This second tuber is fully developed in the fall of the first year, and withers a year afterward, by which time it has produced fruit and developed another (the third) tuber. The parent tuber and its offspring are often met with in the commercial article still united by the short rhizome, or, if detached, showing the scar and often a portion of this branch. As met with in commerce, it is of a conical shape, 2 to 3 inches (50 to 75 Mm.) in length, and about an inch

FIG. 10.

Tubers of *Aconitum napellus*, *Linne*, with a transverse section.

(25 Mm.) in thickness at the crown; the numerous rootlets are mostly broken off, giving the tuber a tuberculated appearance from the remnants of the radicles. At the top it is crowned with a short portion of the stem or with the terminal bud. It is of a dark-brown color externally, longitudinally wrinkled, and breaks with a short, non-fibrous fracture; internally, it is compact and whitish if of latest growth, or brownish, porous, and often hollow if of the previous year's growth. The transverse section shows a thick bark, enclosing a star-shaped six to eight-rayed pith, having a thin, vascular bundle in each ray. The radish-like odor of the fresh root disappears on drying; the taste is at first sweetish, then acrid and burning, with a persistent sense of numbness; which effect furnishes a good criterion of the quality of aconite-root; the shrivelled and porous tubers are usually less efficient. The degree of impression produced upon the tongue by aconite-roots taken at random from a larger quantity is regarded by Dr. Squibb as an approximate test of its value. Dr. A. B.

Lyons (1882) has modified this test by preparing a tincture representing 10 per cent. of the root, and applying a single drop of this to the tongue. By the intensity and the duration of the effect produced one can judge pretty correctly of the value of a given sample.

Admixtures.—The tubers of the allied blue-flowering species of aconitum are sometimes dug up and mixed with the official. The tubers of *Aconitum Cammarum*, *Jacquin* (s. *Ac. variegatum*, *Linne*), are globular-ovate, smaller than the preceding, the central pith about five-rayed and the rays rounded. Those of *Aconitum Stoerckeanum*, *Reichenbach* (s. *Ac. Cammarum*, *Linne*, s. *Ac. Napellus*, *Stoerck*), are often 3 to 5, attached to the parent tuber, of a slender conical shape, and with the pith roundish pentagonal in out-

line. The root of *Imperatoria Ostruthium*, *Linne*, or European masterwort, resembles aconite-tubers in shape, but has an aromatic odor and pungent taste, and exhibits upon transverse section numerous oil-cells arranged in several circles.

2. **ACONITE-LEAVES.** They are alternate, smooth, petiolate, 2 to 3 inches (50–75 Mm.) in length, nearly orbicular in outline, somewhat heart-shaped at the base and divided to the base, the lower into five, the upper into three, segments, each of which is again three or sometimes five-cleft, the last divisions being linear-lanceolate, often toothed, show a prominent rib beneath and a furrow above, which extends into the petiole, this being of about the length of the leaf. The texture of aconite-leaves is somewhat leathery, their color rather bright-green, and somewhat shining above and paler beneath. In the dry state they have a slight herbaceous odor and a taste which soon becomes bitter and acrid, producing tingling upon the tongue. The leaves are usually mixed with a portion of the handsome purplish-blue flowers, which grow in terminal racemes, have the upper sepal helmet-shaped, ending in a short point curved upward, and enclosing two long-stalked but short-bladed petals, and contain numerous hypogynous stamens and three short, slightly divergent ovaries.

The leaves of *Aconitum Stoerckeanum*, *Reichenb.*, are similar in appearance, but the segments are broader; those of *Ac. Cammarum*, *Jacq.*, are less deeply incised and have nearly rhomboid segments.

Other Species of Aconite.—BISH OR BIKH ROOT, also called Nepaul aconite-root, obtained from *Aconitum ferox*, *Wallich*, s. *A. virosum*, *Don*, and perhaps from other species of aconitum indigenous to the Himalayas, is occasionally met with in commerce. It is conical in shape, 2 to 4 inches (5–10 Cm.) long, about 1 inch (25 Mm.) and over in its upper diameter, longitudinally wrinkled, externally of a brownish-black color, internally whitish and somewhat spongy, or compact and of a resinous somewhat translucent appearance upon the smooth and short fracture. Its taste is intensely acrid.

ACONITUM HETEROPHYLLUM, *Wallich*. The conical or fusiform roots of this Himalayan species have a mucilaginous bitter taste without acidity, and are used in India, under the name of *atis*, for their tonic and anti-periodic properties. They are of a yellowish-gray color, rough from the numerous root-scars, internally white and mealy, and contain about $\frac{1}{12}$ per cent. of a bitter non-poisonous alkaloid, *atisine*, which appears to be combined with aconitic acid; the alkaloid was discovered by Broughton.

ACONITUM LYCOCTONUM, *Linne*. Von Schroff (1875) recalled attention to the fact that the aconite-leaves which are used in Lapland as a potherb are from a blue-flowering variety of this species, the *Ac. septentrionale* of Koelle, which contains only a very minute quantity of bitter alkaloid in the leaves, though more in the rhizome and rootlets.

ACON. ANTHORA, *Linne*, a yellowish or white-flowering species of Europe, has bitter roots, which were formerly used as a tonic, and, according to Hooker, the roots of the allied *Acon. multifidum*, as also those of *Acon. rotundifolium*, indigenous to India, are eatable.

ACONITUM CHINENSE, *Siebold*, *Ac. japonicum*, *Thunberg*, and perhaps other species, yield Chinese and Japanese aconite-root, which vary in shape, size, and poisonous properties, and appear in the Eastern market in the dried and salted condition and preserved by steeping in vinegar. Their poisonous properties and their constituents vary according to origin and mode of preservation. Geerts (1880) states that the most toxic Japanese aconite-root consists of the young tubers of *Ac. Fischeri*, *Reich*. Paul and Kingzett have isolated *japaeconitine*, which was found by C. R. A. Wright to closely resemble his aconitine. Langgaard (1880) obtained two alkaloids, *rotoine* and *scopoleine*, possessing a physiological action similar to atropine.

Constituents.—The important medicinal constituent of both aconite root and leaves is the acid alkaloid *aconitine* or *napeaconitine*, combined with aconitic acid associated with bitter amorphous alkaloids, one of which, *napeleine*, was discovered by Hübschmann (1857), and subsequently (1867) found by him to be identical with *acolyetine*, one of the alkaloids obtained by him from *Aconitum Lycoctonum*, *Linne*, which plant contains a second alkaloid, *lycoctonine*, but no aconitine. Wright has shown (1877) that these two alkaloids should be regarded as decomposition-products—namely, *acolyetine* from aconitine, and *lycoctonine* from the principal acid alkaloid of bikh-tubers, which has been named *pseudaconitine*. The last-named alkaloid is also present in very small quantity in aconite-root, from which T. and H. Smith obtained (1864), by almost neutralizing the acid solution of crude aconitine with carbonate of sodium, a crystallizable non-poisonous alkaloid, bearing in its behavior a close resemblance to narcotine, and for which the name of *aconeline* has been proposed. Groves failed (1866) to obtain it, and Wright did not observe it; but the latter proved the existence of two amorphous alkaloids which are soluble in solution of potassium carbonate. One of these, *piceaconitine*, has a bitter taste free from acidity; its composition is represented by the formula $C_{31}H_{45}NO_{10}$, and upon saponification with an alkali it splits into benzoic acid and *piceaconine*, $C_{24}H_{41}NO_9$, the latter resembling the analogous derivative of aconitine. The salts of *piceaconitine* are crystallizable.

Wright's total yield of crystalline and non-crystalline alkaloids from 200 cwt. of aconite-root was 0.07 per cent. Hottot (1864) obtained 0.06, and Hager (1863) between 0.64 and 1.25 per cent. Procter (1863), by testing with Mayer's solution, showed a total of 0.93 per cent. of alkaloids from aconite-root cultivated at New Lebanon, N. Y., and 0.44 per cent. from commercial European aconite-root, but by actual experiment he obtained only 0.42 and 0.20 per cent. respectively.

The herb from which Geiger and Hesse (1833) first isolated the mixed alkaloids usually contains a small percentage thereof, the fresh herb yielding to Wright 0.011 per cent., equal to about 0.05 per cent. of total alkaloids from the dry herb.

Aconite-leaves contain also albumen, gum, chlorophyll, extractive matter, and salts. In aconite-tubers resin, fat, mannit, cane- and grape-sugar have been found; the absence of a volatile alkaloid was demonstrated by Groves (1866).

Aconitic acid, $\text{H}_3\text{C}_6\text{H}_3\text{O}_6$, has been obtained also from *Delphinium Consolida*, *Equisetum fluviatile*, and by the decomposition of citric acid by heating it rapidly in a retort until oily streaks make their appearance in the neck, when the residue is exhausted with ether to free it from the undecomposed citric acid. By this process citric acid is deprived of 1 molecule of water; $\text{C}_6\text{H}_8\text{O}_7$ (citric acid) yields H_2O and $\text{H}_5\text{C}_6\text{H}_3\text{O}_6$. Aconitic acid crystallizes in colorless laminae, or warts, which are easily soluble in water, alcohol, and ether, and which fuse at 140°C . (284°F). Aconitate of calcium = $\text{Ca}_3(\text{C}_6\text{H}_3\text{O}_6)_2 \cdot 6\text{H}_2\text{O}$, dissolves with difficulty in water after it has been in the crystalline state.

Nepaul aconite contains an alkaloid which was at first supposed to be identical with aconitine, but was afterward described under various names, like *acraconitine* (Ludwig, 1869), *napelline* (Wiggers, 1857), and *nepaline* (Flückiger, 1869). The name *pseudaconitine* or *feraconitine* is now given to this substance, which, according to Groves (1870-74), exists in two modifications, one crystalline, but yielding uncrystallizable salts, the other amorphous; the latter becomes sticky in boiling water, while the former coheres and becomes plastic only if treated with boiling water immediately after having been precipitated by ammonia. Another alkaloid, resembling Hübschmann's napelline, but probably differing from it, is likewise met with in bikh-root. Duquesnel (1871) and Patrouillard (1872) regarded pseudaconitine and aconitine as identical, differing from each other merely in the amount of other inert constituents contained in them. C. R. A. Wright (1875-80), however, proved the former to have the composition $\text{C}_{36}\text{H}_{49}\text{NO}_{12}$, and when acted upon by alcoholic solution of soda at 100°C . (212°F .) observed it to be decomposed into *dimethyl-protocatechuic (veratric) acid*, $\text{C}_9\text{H}_{10}\text{O}_4$, and an uncrystallizable base, *pseudaconine*, $\text{C}_{27}\text{H}_{34}\text{NO}_8$, which prevents also the crystallization of pseudaconitine; the latter is closely related to the opium alkaloids narcine and narcotine, which give rise to derivatives of dimethyl-protocatechuic acid. The same author regards Hübschmann's lycocotinine merely as a mixture of these two alkaloids, pseudaconine predominating.

Off. Prep.—*Of the leaves*: Extractum aconiti, Br.; *Of the root*: Aconitia, Br.; Extract. aconiti (fluid.), U. S.; Liniment. aconiti, Br.; Tinctura aconiti (radicis), U. S., Br.

EMPLASTRUM ACONITI.—Emplâtre d'aconit, Fr.; Aconitpflaster, G.—Exhaust by percolation Aconite-root in fine powder, 16 troyounces, with Alcohol. Distil from the tincture the greater part of the alcohol, and evaporate the residue to a soft uniform extract by means of a water-bath. Add to this sufficient resin plaster, previously melted, to make the mixture weigh 16 troyounces, and then mix them thoroughly.—U. S. 1870.

This is an efficient plaster if prepared from good aconite-root, which it represents weight for weight, and the alcoholic extract of which is easily and uniformly incorporated with the resin plaster.

Physiological Action.—Experiments upon fish, serpents, earth-worms, frogs, birds, etc. show that in all these animals aconite causes loss of sensibility, and paralysis terminating in death. The same general effects are exhibited by dogs, but in some instances it is evident that general sensibility is obtunded, if not suspended, even while locomotion is unimpaired. The first effects of a poisonous dose are staggering and weakness of the limbs, then disordered breathing, paralysis of the limbs, general anaesthesia, blindness, imperfect respiration, spasms, and death. Associated with these phenomena are slow pulse and breathing and lowered temperature, followed by rapidity and irregularity of the action of the heart and lungs. After death the stomach is not inflamed and the vessels of the cerebral meninges are gorged with blood. It is inferred from these and other results of experiment that aconite acts primarily upon the extremities of the nerves, and especially of the motor nerves. Upon *man* the following effects have been noted, chiefly in the very numerous cases in

which it has been prescribed in an overdose or been taken by mistake: After a dose of 5 minims of the tincture there is felt a tingling, numb sensation in the lips and tongue and in the tips of the fingers, with a sense of muscular weakness and depression; the pulse falls in frequency and force and the breathing is somewhat slower. A dose of 10 minims produces the same symptoms greatly intensified and more prolonged. Beyond this dose the effects become poisonous; besides tingling of the skin there may be lancinating pains in the joints; there is vertigo with dimness of vision, alarming debility, and a pulse of between 30 and 40 in a minute, which afterward grows frequent and irregular. The skin is cool and moist, nausea and vomiting occur, and the sickness and depression may last for several days. (For illustrative cases see *Edinb. Med. Jour.*, xxviii. 653; Reichert, *Phila. Med. Times*, xii. 105.) In poisonous doses which yet have not proved fatal the preceding symptoms occur in an intensified degree. If the dose is a fatal one, there is complete loss of sight, hearing, and speech, yet consciousness may still be retained; the pupils are dilated, the muscles are tremulous or convulsed, the pulse is imperceptible at the wrist, and may be so even in the axilla; the skin is cold, and death usually takes place by syncope. No characteristic lesions are found after death, but the heart is generally arrested in diastole, and most frequently is filled with dark blood. Large doses of aconite are said to leave behind them general debility, tremulousness, photophobia, feverishness, impaired digestion, and sometimes a tendency to jaundice. Experiments made to determine the influence of aconite on the secretion of urine (Mackenzie, *Practitioner*, xxiv. 1) appear to show that in obstructive heart or kidney disease it neither maintains the action of the kidneys nor evacuates dropsical fluid, but that where these conditions do not exist, and in certain febrile states, it has a tendency to increase the urinary secretion. (Further information regarding the action of this drug will be found under ACONITIA.)

Medical Uses.—Aconite has been proclaimed by not a few writers of authority to be a potent remedy for *rheumatism*; it may be admitted to possess some value as a sedative of arterial action, and thereby as an indirect anodyne, but it is in no proper sense a remedy for the disease. Indeed, it falls so far short of alkalies in the articular, and of iodide of potassium in the muscular, variety of rheumatism that its practical value is next to nothing, and it does not enter into the catalogue of remedies which are prescribed for the disease by judicious practitioners. It is of still less utility in *gout* than in rheumatism. But in both affections it may be employed as a topical application for mitigating pain. So far as the internal use of aconite in *neuralgia* is concerned, a somewhat analogous judgment may be given. Undoubtedly it sometimes palliates severe suffering in this disease affecting the nerves of the face or the chest, especially when it is at the same time applied, in the form of a strong tincture, over the superficial and painful nervous branches. Aconite plaster, which is no longer officinal, may be used in a similar manner, and as a sedative of local pain in chronic *rheumatism*, *white swelling*, etc. In the greater number of cases of neuralgia, not the direct effect of external causes, the affection depends upon states of the system which must be remedied by quinia, arsenic, iron, etc., and in which the sole indication for aconite is fulfilled by its local application. It is sometimes very efficient in relieving *toothache* when introduced into a carious cavity. But the risk of poisoning in such cases outweighs the advantages of the medicine. The same reflection is suggested by its use in *palpitation* of the heart, whether nervous or arising from organic disease of that organ, in *dysentery*, *amenorrhœa*, etc. In traumatic *tetanus* a like consideration should forbid its use, in spite of certain cases in which it seems to have been advantageous.

The statements which have been made respecting the virtues of aconite in purely inflammatory affections and fevers—*e. g. pneumonia*, *tonsillitis*, *rheumatism*, *erysipelas*, *typhoid fever*, *puerperal fever*, *remittent fever*, and *traumatic fever*—have not been supported by concurrent experience. Probably the medicine is more efficient in acute *tonsillitis* than in the other diseases enumerated. But if certain reports of its use in *pneumonia* (*e. g. Spark, Practitioner*, xxii. 196; Dobie, *ibid.*, p. 401) were to be taken as a guide, it has effected what no other medicine can do. It is said to have cut short the disease within from 1 to 3 or 4 days of its commencement. Evidently, the reporters have overlooked the fact that pneumonia sometimes does not go beyond the first or congestive stage. Like various other sedatives and more numerous stimulants, aconite will sometimes prevent the development of certain diseases, such as coryza, tonsillitis, laryngeal and bronchial catarrhs, and even nervous asthma. Walsh has commended the use of aconite in *pericarditis* when the general conditions are sthenic and the disease is at its onset; and yet he admits that an overdose of it will dangerously accelerate the heart's action and lessen its power.

The risks greatly outweigh the benefits of its administration in this as in all other internal diseases. It seems to rest upon the same error which led to the employment on the one hand of digitalis and on the other of white and green hellebore in such affections, and which consisted in mistaking a reduction of the pulse-rate for the cure of the disease which caused its increase. It should constantly be borne in mind, in reference to the two last-mentioned medicines, and still more in regard to aconite, that the lowering effect upon the pulse is brought about at the expense of the power of the heart. When employed in fevers and inflammations, it should always be given in very small and frequently repeated doses, such as half a minim every quarter or half hour until some of its characteristic effects appear, when the dose should be diminished or given at longer intervals.

The treatment of *poisoning* by aconite consists in evacuating the stomach with mechanical emetics and the stomach-pump, and sustaining vitality by means of the galvanic battery and by the administration of stimulants, including alcoholic liquids, coffee, and external heat. Oxygen has apparently tended to revive failing life, and hence artificial respiration is indicated. Strychnia is regarded as indicated physiologically; and digitalis, or, preferably, digitalin and atropia, may be given for their sustaining operation upon the heart. (For the use of these agents in poisoning by aconite see ATROPINA and DIGITALIS.) Two cases occurred (O'Brien, *Med. Record*, xv. 128; Clark, *ibid.*, xvii. 6) which demonstrate the power of *morphia*, hypodermically administered, to rescue from impending death persons poisoned by aconite, and others have been recorded. To assist in preventing syncope the patient's head should be kept low. According to Harley, death results from asphyxia and progressive collapse of the lung, the former being due to the spasmodic closure of the respiratory passages and paralysis of the muscles of inspiration, and notably of the diaphragm.

Dose.—Of the powdered leaves or root 1 or 2 grains (Gm. 0.06–0.13) are a minimum dose, but aconite is seldom employed in this form. The extract and tincture are preferable for internal administration, and for the local effects of the medicine either the tincture, aconite plaster, or aconitia may be employed. It must not be forgotten that alarming symptoms have been produced by a dose of 3 drops (Gm. 0.02) of the saturated tincture of aconite-root.

Napelline (probably Hübschmann's) is alleged by Laborde to produce essentially the same effects as aconitia, but only when given in a much larger dose than the latter. Thus, while half a milligram (gr. $\frac{1}{120}$) of aconitine fatally poisons a dog, it requires 3 or 4 centigrams (gr. $\frac{1}{4}$ to $\frac{3}{4}$) of napelline to produce any effect on a similar animal. It is also asserted that napelline induces a calm and refreshing sleep, like that occasioned by narcaine (*Bull. de thérap.*, ciii. 94). It would be a singular fact if a derivative of aconite should possess soporific qualities that do not belong to the drug itself (see p. 115). In doses of half a grain napelline is said to have been a very efficient palliative of *neuralgia* of the fifth nerve. It has also been given for the relief of this affection in doses of one-twenty-fourth of a grain every 2 hours (*Bull. de thérap.*, cv. 220).

ACTÆA SPICATA, *Linné*.—BANEERRY ROOT.

Radix Christophoriana.—*Racine de Saint-Christophe*, Fr.; *Christophseurzw*, *Wolfswurzw*, G.

Nat. Ord.—*Ranunculacæ*, *Cimicifugæ*.

Origin.—The plant is a native of Central and Northern Europe, and a variety with red berries (*A. rubra*, *Bigelow*) is indigenous to the Northern United States and Canada. The leaves are twice or thrice ternately compound, with ovate or oblong, sharply cleft or toothed leaflets. The whitish flowers are in short, dense racemes. The fruit of the European variety is glossy black. Another American species, *A. alba*, *Bigelow*, is taller and has longer racemes and white berries.

Description.—The rhizome and rootlets closely resemble the corresponding parts of *cimicifuga*, but are shorter, thinner, and of a blackish-gray color. When dry they are nearly inodorous; their taste is bitter, afterward acrid and sweetish. The constituents are similar to those of *cimicifuga*.

Physiological Action and Medical Uses.—*A. spicata*, or baneberry, and *A. alba* and *rubra*, are sometimes used in domestic medicine where they flourish—the first in Europe, the others in this country. They are probably very analogous, if not identical, in their mode of action, which is that of an irritant emeto-cathartic. The berries of the European species are said to occasion violent and even fatal delirium, as well as gastrointestinal disorder. They destroy the life of hens and ducks, but sheep, asses, and goats devour the green leaves without injury. The powder and decoction are used to kill *fleas*

and *lice*. The fresh root of the plant has been used in veterinary medicine, and was formerly regarded as a remedy for *asthma*. Whatever virtues belong to either of these species probably exist more perfectly in *cimicifuga*. *A. spicata* is administered in an infusion made with 30 grains (Gm. 2), to be taken in 1 day.

ADANSONIA DIGITATA, *Linné*.—BAOBAB.

Baobab, E., Fr., G.

Nat. Ord.—Sterculiaceæ, Bombacææ.

Description.—The tree is indigenous to tropical Africa, and has been introduced and naturalized in various parts of the East and West Indies. It is remarkable for its enormous size, the trunk being about 15 feet (4.5 M.) high up to the branches, but attaining a circumference of 100 feet (30 M.) and more, and being divided into branches 50 to 70 feet (15–21 M.) long. It has a smooth, gray bark; palmate leaves, with 5 to 7 obovate or elliptic rather acute and somewhat dentate leaflets, which are about 5 inches (12 Cm.) long. The flowers are about 4 inches (10 Cm.) long and wide, have 5 thickish, obovate, white petals, and numerous stamens, with the lower half of the filaments united into a tube, and produce a roundish, oblong fruit about 10 to 12 inches (25–30 Cm.) long and containing about 50 blackish, subreniform seeds, which are covered with a whitish, acidulous pulp. The bark, leaves, and flowers have a mucilaginous taste. The fruit is known as *monkey-bread* (*Pain de singes*, Fr.: *Affenbrot*, G.), *Ethiopian sour-gourd*, and in Southern Africa as *cream-of-tartar fruit*. The pulp surrounding the seeds contains, according to F. L. Slocum (1880), acid potassium malate, pectin, and glucose.

The Australian species, *A. Gregorii*, *F. v. Mueller*, is of smaller dimensions.

Medical Uses.—The bark of the baobab does not appear to affect any of the functions, except perhaps by increasing the appetite. The natives of Senegal are said to use it for its emollient qualities, and to mix the powder of its leaves with their food. It at first attracted attention in consequence of its alleged power of curing *intermittent fever*, but no confirmation of the original assertion is accessible, and it is quite improbable that a mucilaginous plant should possess such a virtue. A decoction is made with an ounce of baobab-bark and a quart of water (Gm. 32 in 1000), reduced by boiling to a pint and a half.

ADEPS, U. S.—LARD.

Adeps preparatus, Br.: *Adeps suillus*, P. G.; *Acungia*, *Acungia porci* s. *porcina*.—*Prepared lard*, *Hog's lard*, E.: *Aconge*, *Graisse de porc*, *Saindoux*, Fr.; *Schweineschmalz*, G.

The prepared or purified internal fat of the abdomen of the hog, *Sus scrofa*. *Linné*.

Class Mammalia; order Pachydermata.

Preparation.—For medicinal purposes the fat attached to the mesentery, omentum, and kidneys of the hog killed during the winter or spring should be selected, as this has a higher fusing-point than if obtained during the summer or from other parts of the body. It is that portion which is ordinarily called the “leaves,” and should be as free from blood as possible. Hogs which have been fed on corn and similar amylaceous food appear to yield a more solid lard than hogs fed on the refuse of the kitchen. The British Pharmacopœia gives the following directions for preparing lard: Take of the internal fat of the abdomen of the hog, perfectly fresh, 14 pounds. Remove as much of the membranes as possible; cut the fat into small pieces, put it into a suitable vessel with about 4 gallons of cold water, and, while a current of water is running through the vessel, break up the masses of fat with the hands, exposing every part to the water, so that whatever is soluble may be thus dissolved and carried away. Afterward collect the washed fat on a sieve or in a cloth; drain away as much as possible of the water, liquefy the fat at a heat not exceeding 212° F., and strain through flannel, pressing the residue while hot; then put it into a pan heated by steam, and keep it at a temperature a little but not much above 212° F., stirring it continually until it becomes clear and entirely free from water; finally, strain it through flannel.—*Br.*

Perfumers obtain it inodorous, or nearly so, by adding to every pound of the fused lard about 15 grains of powdered alum and 30 grains of table-salt, and continuing the heat until a scum rises, which is to be carefully removed, and the fat is uniform in appearance; it is then allowed to cool, and worked upon a slab or in a mortar while a slow stream of clear water passes over it, whereby the salts are completely removed. The fat is then remelted and the heat maintained until the water has completely separated or evaporated.

Properties.—Lard is a soft white fat, having a faint odor entirely free from rancidity, a bland taste, and a neutral reaction; like other fats it dissolves completely in ether, benzin, benzol, carbon disulphide, chloroform, and volatile oils. It has a density of about 0.938, fuses near 35° C. (95° F.) to a clear, nearly colorless liquid, and at or below 30° C. (86° F.) is a soft solid. In contact with the air, particularly when exposed to the light, it speedily oxidizes and becomes rancid, acquiring an acid reaction, a disagreeable odor, and an acrid taste; this change is accelerated by the presence of alkalies.

As met with in commerce, lard often has a rancid odor, and is then unfit for medicinal use. Salt is often added to prevent it from becoming rancid, but should be carefully removed by fusing the lard and stirring it in hot water, and afterward washing it until the fat is tasteless or nitrate of silver ceases to produce a precipitate with the washings. Carbonate of potassium is used to impart an artificial whiteness to commercial lard and to incorporate with it considerable proportions of water; such lard is to be purified by remelting and washing with water. Adulterations with mucilaginous jellies are removed in the same manner.

Constituents.—Lard is a mixture of olein, palmitin, and stearin, the last two fats being obtainable to the amount of 30 to 40 per cent. by subjecting the lard to pressure near the freezing-point of water. The expressed liquid is known in commerce as *lard oil*, and is extensively used for various purposes; it furnishes a cheap adulterant for some of the more costly non-drying oils. The solid portion is called *stearin*, and is employed for making candles, soap, etc. When melted lard is allowed to cool slowly a portion of the solid fats separates in granules; hence lard and all its preparations should be constantly stirred while cooling, to obtain them of uniform smoothness.

Preservation and Tests.—Lard should be preserved in glass, porcelain, or other well-glazed vessels, which must be entirely impervious to fat; the vessels should be well filled and protected from the access of air and light. Rancidity is readily ascertained by the acid reaction which alcohol acquires on being agitated with melted lard. On melting lard in a narrow test-tube, the oily liquid should be perfectly transparent and not separate a stratum of water. The adulterations mentioned above are detected by ether or chloroform, in which they are insoluble; distilled water, on being boiled with lard, should not acquire an alkaline reaction (alkaline carbonates), and after separating the fat the liquid should not form a precipitate with nitrate of silver (sodium chloride) or assume a blue color on the addition of compound solution of iodine (absence of starch).

ADEPS BENZOINATUS, U. S.—BENZOINATED LARD.

Adeps benzoïnatus, Br.; *Unguentum benzoïnî*, U. S. 1870; *Arungia balsamica* s. *benzoïnata* s. *benzoata*.—*Benzoated lard*, *Ointment of benzoïn*, E.; *Aronge* (*Graïsse*) *benzoïnée* (*balsamique*), Fr.; *Benzoïnirtes Schmalz*, G.

Hog's lard impregnated with benzoic acid and the odorous principle of benzoïn.

Preparation.—Benzoïn, in coarse powder, 2 parts; Lard, 100 parts. Melt the lard by means of a water-bath, and, having loosely tied the benzoïn in a piece of coarse muslin, suspend it in the melted lard, and, stirring them together frequently, continue the heat for 2 hours, covering the vessel and not allowing the temperature to rise above 60° C. (140° F.). Lastly, having removed the benzoïn, strain the lard, and stir while cooling.—U. S.

Take of prepared Lard 1 pound; Benzoïn, reduced to coarse powder, 160 grains. Melt the lard by the heat of a water-bath, add the benzoïn, and, frequently stirring them together, continue the application of heat for 2 hours; finally, remove the residual benzoïn by straining.—Br.

The result of both processes is practically identical, though the first formula directs for 1 pound avoirdupois only 140 grains of benzoïn. By enclosing the latter in a muslin bag and regulating the temperature the benzoïn is more thoroughly exhausted than if it was allowed to melt, and empyreuma is prevented. As prepared by the U. S. Pharmacopœia of 1870, by mixing 2 fluidounces of tincture of benzoïn with 16 troyounces of melted lard, it was necessary to strain after the evaporation of the alcohol, so as to remove the resin, which has an irritating effect on tender surfaces.

Fixed oils dissolve the benzoic acid and odorous principles contained in benzoïn. Pure benzoic acid has no preservative influence on lard; that property appears to be due solely to the balsamic principle of benzoïn and similar bodies. Hence the rancidity of lard may be prevented by impregnating it with the balsamic principles of storax, Peru or Tolu balsam, in the proportion of 1 or 2 parts of balsam to 100 parts of lard; the latter constitutes the so-called *balsamic lard* (Procter, 1863). In a similar manner *populated lard*

(*Unguentum populi s. populeum*) is obtained by digesting 1 part of poplar-buds and 2 parts of lard until the moisture has evaporated, when the undissolved matter is removed by expressing and straining. B. F. Scholl (1883) ascertained that for the preservation of fats a larger amount of storax is required than of benzoïn. Groves found (1866) that volatile oils generally preserve fats from rancidity to some extent, and that the oils of cloves, allspice, and sassafras are best adapted for this purpose, in the proportion of 4 drops to 1 ounce of fat.

Pharmaceutical Uses and Preparations.—Lard and benzoïnated lard are used as ingredients in ointments, cerates, and sometimes also in plasters as a substitute for olive or other oil. The base of the following ointments is lard only: Ung. aconitiæ, Ung. atropiæ, Ung. belladonnæ, Ung. hydrargyri subchloridi, Ung. iodi, Ung. potassæ sulphuratæ, Ung. potassii iodidi, Ung. sulphuris iodidi, Ung. veratriæ, *Br.*

The following ointments are made with benzoïnated lard for their base: Ung. acidi gallici, Ung. acidi tannici, Ung. belladonnæ, Ung. chrysarobini, *U. S.*; Ung. gallæ, *U. S.*, *Br.*; Ung. hydrargyri ammoniati, Ung. iodi, Ung. iodoformi, *U. S.*; Ung. plumbi acetatis, *Br.*; Ung. plumbi carbonatis, Ung. plumbi iodidi, Ung. potassii iodidi, Ung. stramonii, *U. S.*; Ung. sulphuris, *U. S.*, *Br.*; Ung. sulphuris alkalinum, Ung. veratrinæ, *U. S.*; Ung. zinci oxidi, *U. S.*, *Br.* Benzoïnated lard enters also into the suppositories of the British Pharmacopœia.

Lard is also an ingredient in the following: Ceratum, *U. S.*; Ceratum (emplastrum) cantharidis, *U. S.*, *Br.*; Cerat. extr. canthar., Cerat. resinæ, *U. S.*; Unguentum (simplex), Ung. hydrargyri, *U. S.*, *Br.*; Ung. mezerei, *U. S.*; Ung. sabinae, Ung. terebinthinæ, *Br.*

Physiological Action and Uses.—Lard is used in medicine chiefly on account of the property it possesses in common with all unctuous substances of facilitating manual and mechanical operations by its lubricating qualities, and also because it shares the same property of protecting exposed tender surfaces from the action of the air. Like other fats and oils, it is difficult of digestion, and therefore is sometimes used as a laxative for children and for its protective power in *diarrhœa*, *dysentery*, etc. Enemata of melted fresh lard are extremely soothing in acute dysentery. It has been proposed as a substitute for cod-liver oil in the treatment of *phthisis*, but its indigestible nature unfits it for this purpose. It has been employed externally in the same disease by inunction of the chest, and probably with the advantage of protecting the lungs from the external impression of cold. In the treatment of bronchial and laryngeal *catarrh* in children, and indeed of all pulmonary affections of early life, this simple application is valuable, not only for the reason assigned, but because it seems, when the cough is dry and urgent, to render expectoration freer. The same may be said of its use in *coryza*, in which the ointment should be applied on the bridge of the nose. In *scarlet fever* inunction of the whole body protects the skin from the atmosphere, and thereby lessens the burning and itching, and both directly and indirectly lowers the temperature and the pulse-rate. It also tends to prevent a sudden chill on exposure to the air, and hence diminishes very much the occurrence of scarlatinous *dropsy*. But with this end in view the application must be continued for some time after the acute febrile symptoms have disappeared. It is thought that the anginous symptoms of scarlet fever may be moderated by keeping the neck enveloped in well-greased flannel cloths, but of this the evidence is slender. In *measles* it is probable that the *bronchitis* may be moderated by similar applications upon the chest. The best form in which lard can be used for the above purposes is simple ointment. The strongest objections to its use are the necessity of soiling much body- and bed-clothing, and the repugnance which is generally manifested by patients to its frequent repetition. Benzoated lard, especially with a modicum of glycerin, is preferable to prepared lard or simple ointment when a mild stimulant action is desired besides the protective influence.

ADIANTUM.—MAIDENHAIR.

Herba capillorum veneris.—*Capillaire*, Fr.; *Frauenhaar*, *Venushaar*, G.

The frond of *Adiantum capillus Veneris*, *Linné*, and *A. pedatum*, *Linné*.

Nat. Ord.—Filices.

Origin.—The first species is indigenous to Southern Europe, and grows in moist rocky places; the second is common in rich moist woods of North America.

Description.—The European maidenhair has a polished, blackish-brown stipe about a foot (30 Cm.) high, tri- or bipinnate below, pinnate above; the leaflets are short-stalked, irregular, roundish wedge-shaped, oblique at the base, obtusely lobed, and with linear marginal fruit-dots. The American species has the stipe forked at the summit, each branch

recurved and with 6 or 7 pinnate branches; the leaflets are triangular oblong, on the lower margin entire, the upper margin cleft and fruit-bearing; otherwise resembling the preceding. Both have a faintly astringent, sweetish, and slightly bitter taste; the American maidenhair has also a faint aromatic odor. Their constituents are a small quantity of tannin, a bitter principle, mucilage, sugar, and a trace of volatile oil.

Pharmaceutical Uses.—*SYRUPUS ADIANTI*, *S. CAPILLORUM VENERIS*.—Syrup of maidenhair, *E.* As employed in Europe, it is prepared by making an infusion with 1 part of the drug and 10 parts of boiling water, and dissolving in the strained liquid 19 parts of sugar.

Allied Species.—Other species indigenous to Mexico and South America are employed there for similar purposes. *Asplenium Adiantum nigrum*, *Linné*, was formerly known in Europe as *black maidenhair*, and *Aspl. ruta muraria*, *Linné*, as *white maidenhair*; the latter is also a native of the United States.

Medical Uses.—The indigenous species of maidenhair is reputed to be useful in the same affection for which its European congener has long been celebrated—viz. in *pulmonary catarrh*; and a syrup made with the latter species is, in France, an ordinary flavoring addition to expectorant mixtures. It is demulcent and slightly stimulant.

ÆTHER, *U. S., Br., P. G.*—ETHER.

Æther sulphuricus, *Naphtha vitrioli*.—*Sulphuric ether*, *E.*; *Æther hydrique s. vinique s. sulfurique*, *Fr.*; *Æther*, *Schwefeläther*, *G.*

Ether of the specific gravity 0.750 (*U. S.*), 0.735 (*Br.*), 0.724–0.728 (*P. G.*), 0.720–0.725 (*F. Cod.*).

Stronger or pure ether has a specific gravity not exceeding 0.725 (*U. S.*), 0.720 (*Br.*).

Formula $(C_2H_5)_2O$. Molecular weight 74.

Preparation.—Take of Rectified Spirit 50 fluidounces; Sulphuric Acid 10 fluidounces; Chloride of Calcium 10 ounces; Slaked Lime $\frac{1}{2}$ ounce; Distilled Water 13 fluidounces. Mix the sulphuric acid with 12 fluidounces of the spirit in a glass matrass capable of containing at least 2 pints, and, not allowing the mixture to cool, connect the matrass, by means of a bent glass tube, with a Liebig's condenser, and distil with a heat sufficient to maintain the liquid in brisk ebullition. As soon as the ethereal fluid begins to pass over, supply fresh spirit through a tube into the matrass in a continuous stream, and in such quantity as to equal the volume of the fluid which distils over. For this purpose use a tube furnished with a stopcock to regulate the supply, connecting one end of the tube with a vessel containing the spirit raised above the level of the matrass, and passing the other end through a cork fitted into the matrass. When the whole of the spirit has been added and 42 fluidounces have distilled over the process may be stopped. Dissolve the chloride of calcium in the water, add the lime, and agitate the mixture in a bottle with the impure ether. Leave the mixture at rest for 10 minutes, pour off the light supernatant fluid, and distil it with a gentle heat until a glass bead of specific gravity 0.735, placed in the receiver, begins to float. The ether and spirit retained by the chloride of calcium and by the residue of each rectification may be recovered by distillation and used in a subsequent operation.—*Br.*

The details of the process of the *U. S. Pharmacopœia* of 1860 and 1870 were elaborated by Dr. Squibb in 1858, and may be briefly stated as follows: 36 troyounces of sulphuric acid are gradually added to 2 pints of strong alcohol contained in a 6-pint tubulated retort; by means of a sand-bath the liquid is rapidly heated to between 130° and 138° C. (266° and 280° F.), and 4 pints of strong alcohol are then run into the retort in a continuous stream, the flow being regulated so that the temperature of the boiling liquid shall be maintained between the limits mentioned, and the distillation being finally discontinued when the temperature rises to 141° C. (286° F.). The distillate is well agitated with a solution of 360 grains of potassa in 3 fluidounces of distilled water; after 24 hours the supernatant liquid is decanted into a retort, and with a gentle heat distilled until the distillate attains the required specific gravity. Yield, about 3½ pints.

Etherification.—When alcohol and sulphuric acid are mixed, 1 molecule of each compound unites to form sulphovinic acid and water; $C_2H_6O + H_2SO_4$ yields $C_2H_5HSO_4$ (sulphovinic acid) + H_2O . On the application of heat and in the presence of a fresh portion of alcohol a further reaction takes place, whereby sulphuric acid is reproduced and ether formed, the latter distilling over; $C_2H_5HSO_4 = (C_2H_6O) + H_2SO_4$ yields H_2SO_4 and $(C_2H_5)_2O$. The apparent result of the entire reaction, it will be noticed, consists in the abstraction of 1 molecule of water from 2 molecules of alcohol, the remaining elements forming

1 molecule of ether, while the sulphuric acid remains free, merely determining by its affinity for water the decomposition of the alcohol. The incorrectness of such an explanation of etherification is readily demonstrated by the different products of decomposition obtained in case the supply of alcohol is insufficient or the sulphuric acid is used in excess, when oil of wine, sulphurous acid, olefiant and other gases, are generated. (See *OLEUM ÆTHEREUM*.)

By calculation upon the above equation for the production of sulphovinic acid, it will be found that 2 parts of sulphuric acid require nearly 1 part of strong alcohol for the formation of sulphovinic acid, and subsequently the same weight of alcohol is required to decompose all the sulphovinic acid, with the production of ether. However, if the whole amount of the alcohol is added at once, a considerable portion of it will distil over before the temperature of etherification has been attained. In practice, the addition of about 10 per cent. of the second part of alcohol has been found most advantageous, making the proportion of acid and alcohol 9 parts of the former to 5 parts of the latter. This proportion has been adopted in the British Pharmacopœia; in the United States authority a somewhat larger amount (about 6 parts) of alcohol was directed for 9 parts of sulphuric acid. If the quantity of alcohol is increased beyond the proportions given, the boiling-point of the mixture will be lowered and a proportionate amount of alcohol will distil over with the ether. On the other hand, a reduction of the alcohol below the proportions indicated will result in an increase of the boiling temperature and the production of a larger or smaller amount of the decomposition-products mentioned above.

As the ether distils over, a sufficient amount of alcohol is admitted into the retort, so as to maintain the original proportion of the two liquids. This part of the process requires careful attention, and is determined either by comparing the bulk of the alcohol added with that of the distilled ether, or, more practically, by keeping the boiling-point of the liquid in the retort between the limits given above. If the boiling-point should rise above 138° C. (280° F.), the supply of alcohol is insufficient, and if the temperature should fall below 130° C. (266° F.), alcohol has been added too freely, and the excess must be removed by cutting off its flow, either partly or entirely, until the proper temperature has again been reached.

Since in the formation of ether sulphuric acid is continually regenerated, its power of etherification is theoretically unlimited; practically, however, it ceases when about five or six times its weight of alcohol has been subjected to its influence. The main cause for this limit is found in the water which in the course of the process accumulates in the retort and weakens the sulphuric acid. In the beginning of the distillation a considerable proportion of the liberated water comes over with the ether, so that the distillate separates into two layers. As the acid in the retort becomes weaker, a larger proportion of alcohol evaporates with the ethereal and aqueous vapors, so that after some time the distillate will be found to be a clear and uniform mixture of ether, alcohol, and water. The pharmacopœias do not direct the preparation of ether to be pushed to the utmost limit of the etherizing power of the sulphuric acid, but when about double its weight of alcohol has been used the process is discontinued.

The crude ether obtained by the Pharmacopœia process consists of ether, alcohol, and water, but contains, besides these, variable proportions of other decomposition-products, among which sulphurous acid, oil of wine, and occasionally acetic acid, are found. The acids are removed by agitating the crude product with an alkali—potassa or lime—in the presence of water, the latter serving also the purpose of abstracting much of the alcohol from the ethereal liquid. To avoid the loss of too large a quantity of ether, the potassa is dissolved in a small quantity of water, or, as directed by the British Pharmacopœia, a larger proportion of a nearly concentrated solution of calcium chloride containing slaked lime is used, which dissolves the alcohol, but only a small quantity of ether. When the aqueous liquid after sufficient agitation has subsided, the ether is drawn off and rectified until the distillate has the proper specific gravity, which is conveniently ascertained, according to the British Pharmacopœia, by keeping in the receiver a glass bead of the proper density, which will begin to float as soon as the density of the distillate is the same. This rectification is best performed by placing the retort in a water-bath, then heating the bath and carefully regulating the heat, so that the ebullition never becomes violent, in which case the vapors are apt to escape condensation and to become ignited. The condenser should be capacious and well cooled whenever ether is distilled.

Older Theories.—Ether, or a mixture of ether and alcohol, was probably obtained by the alchemists in the thirteenth century, but a process for its preparation from equal parts of oil of vitriol and alcohol was first devised, in the sixteenth century, by Valerius Cordus,

who called it *oleum vitrioli dulce verum*. The name "ether" (spiritus æthereus) was first used for this liquid by Frobenius in England (1730). Fourcroy and Vauquelin (1797) regarded ether as alcohol deprived of water by the action of sulphuric acid, and Valentin Rose proved (1800) that ether contains neither sulphur nor an acid. Berzelius explained the action of sulphuric acid upon alcohol by catalytic force. Liebig regarded sulphovinic acid as a double sulphate of water and ethylic oxide (ether), which is decomposed by heat, with the liberation of ether. Rose explained this decomposition by water displacing the ether from the compound mentioned. Graham ascribed the result to the polymerizing power of sulphuric or sulphovinic acid, whereby alcohol = $C_2H_5 + HO$ (old notation) is converted into ether = $C_4H_8 + HO$. According to Robiquet (1854), carbylic sulphate = $C_2H_4S_2O_3$ and water are first formed, and these, with alcohol, yield ether and sulphuric acid; thus: $C_2H_4S_2O_3 + 2H_2O + C_2H_5O = C_4H_8O + 2H_2SO_4$. The theory explained at the beginning of this article was first advanced by Williamson (1850-54), and is supported by the discovery of ethers containing two distinct alcohol radicals.

STRONGER (PURE) ETHER.—Æther fortior, *U. S.*; Æther purus, *Br.*; Æther, *P. G.*—Stronger ether, Pure ether, *E.*; Ether hydrique pur, *Fr.*; Reiner Äther, *G.*

Take of Ether and Distilled Water, each 2 pints; Lime recently burned $\frac{1}{4}$ ounce; Chloride of Calcium 4 ounces. Put the ether with 1 pint of the water into a bottle, and shake them together; allow them to remain at rest for a few minutes, and when the two liquids have separated decant off the supernatant ether; mix this with the remainder of the water, and again, after separation, decant as before. Put now the washed ether, together with the lime and chloride of calcium, into a retort to which a receiver is closely attached; let them stand for 24 hours, then distil with the aid of a gentle heat.—*Br.*

The process of the *U. S. Pharmacopœia* of 1870 differed from the preceding one in this, that the ether was agitated with an equal bulk of water, then decanted, agitated with calcium chloride and lime in powder, set aside for 24 hours, decanted, and distilled until about one-half had been recovered, the remainder yielding a weaker distillate.

The object of these processes is the removal of alcohol by agitating the ether with water, the last portions of which, together with nearly the whole of the remaining alcohol, are afterward separated by the calcium chloride and lime, the latter of which should be used unslaked. The distillation may be continued as long as ether of the proper specific gravity is obtained. The weaker ether, recovered by continuing the distillation, may be reserved for a subsequent operation.

Properties.—1. **ABSOLUTE ETHER.** It is a colorless, very limpid, not solidifiable liquid, of a strong refractive power, and having a specific gravity of 0.710 at 20° C. (68° F., Richter), to 0.712 at 25° C. (77° F., Gay-Lussac). It has a peculiar penetrating odor and a sweetish, pungent taste. It boils at 34° to 35° C. (93° to 95° F.), the vapors having a specific gravity of 2.58, and volatilizes very rapidly at ordinary temperature, thereby producing a considerable diminution of temperature. It is easily ignited, and burns with a bright flame, yielding water and carbonic acid. Its vapor, mixed with a large quantity of air, if ignited explodes with great violence. In consequence of this property and of the great density of its vapor great care should be exercised in handling ether or manipulating with it in the vicinity of a flame. It dissolves phosphorus, sulphur, iodine, bromine, some metallic sulphides, chlorides, bromides, and iodides, bromoform, iodoform, chloroform, alcohols, benzol, benzin, fats, volatile oils, many resins, most alkaloids, and some organic acids. W. H. Greene (1879) observed that on mixing 20 Gm. of absolute ether with 43 Gm. of chloroform the temperature rises 15° C. and little contraction in volume takes place; the mixture begins to boil at 50° C., and may be separated into its constituents by repeated fractional distillation. When shaken with an equal bulk of water, absolute ether loses one-fourteenth of its volume, which is dissolved by the water, a little of this liquid being dissolved by the ether (Boullay). The presence of water and alcohol is detected by mixing the ether with an equal bulk of carbon bisulphide, which should result in a perfectly clear liquid; a piece of potassa kept in the ether for 24 hours becomes coated with a yellowish film and imparts a yellowish color to the liquid if alcohol be present (Boettger, 1872). Aniline-violet is insoluble in absolute ether, but in the presence of 1 per cent. of alcohol colors the liquid distinctly (Stefanelli, 1875). Well-dried powdered tannin remains pulverulent in absolute ether, but in the presence of water forms a tough mass or thick solution. Frederking (1870) recommended glycerin for the detection of water and alcohol.

Ether has a neutral reaction to test-paper, but when kept for a long time in partly-filled bottles acquires an acid reaction from free acetic acid; this is regarded as the result of oxidation, facilitated by the presence of moisture, or, as suggested by N. E. Henry, to the

decomposition of a little acetic ether assumed to be present in ether. According to Lieben (1873), alcohol is very slowly regenerated when ether is left in contact with water. That ether is capable of forming a hydrate was shown by Tanret (1878), who on filtering an ethereal liquid observed on the upper part of the filter a frost-like congelation having the temperature -3.5°C . (25.7°F .), and, after removing adhering ether by blowing upon it, yielding 17 to 18 parts of water for 37 of ether; the formula $(\text{C}_2\text{H}_5)_2\cdot 0.2\text{H}_2\text{O}$ requires 18 parts.

2. STRONGER OR OFFICIAL PURE ETHER has a density of not over 0.725 at 15°C . (59°F .) or 0.716 at 25°C . (77°F .), and is composed of about 94 per cent. of ethyloxiide (absolute ether) and about 6 per cent. of alcohol containing a little water; it boils at 37°C . (98.5°F .), and dissolves in 8 times its volume of water at 15°C . (59°F .). The specific gravity of ether required by other pharmacopœias is not exceeding 0.720 at 60°F . (*Br.*), 0.720 to 0.725 at 15°C . (*F. Cod.*), 0.724 to 0.728 at 15°C . (*P. G.*); the last-named authority requires that water after agitation with an equal volume of ether should not be increased in volume more than 10 per cent.

If a piece of pale-blue litmus-paper moistened with water be immersed 10 minutes in a portion of the ether, the color should not change. On evaporating at least 50 Cem. in a glass vessel no fixed residue should appear, and on evaporating a portion dropped upon blotting-paper no foreign odor should be developed. When 10 Cem. are agitated with an equal volume of glycerin in a graduated test-tube, the ether layer, when fully separated, should not measure less than 8.6 Cem. It should boil actively, in a test-tube half-filled with it and held a short time in the hand, on the addition of small pieces of broken glass.—*U. S.*

3. OFFICIAL ETHER. Its specific gravity is 0.750 (0.735, *Br.*). It evaporates without residue, does not redden litmus, and when 10 Cem. of it are shaken with an equal bulk of glycerin it should not be reduced to less than 7.5 Cem.

Hager gives the following table, showing the percentage by weight of ether of the specific gravity 0.7185, contained in the alcoholic distillates obtained in the rectification of ether; temperature 17.5°C . (68.5°F .):

Per ct. ether.	Specific gravity.	Per ct. ether.	Specific gravity.	Per ct. ether.	Specific gravity.	Per ct. ether.	Specific gravity.	Per ct. ether.	Specific gravity.
99	0.7198	89	0.7290	79	0.7397	69	0.7516	59	0.7640
98	0.7206	88	0.7300	78	0.7408	68	0.7528	58	0.7653
97	0.7215	87	0.7310	77	0.7420	67	0.7540	57	0.7666
96	0.7224	86	0.7320	76	0.7432	66	0.7552	56	0.7680
95	0.7233	85	0.7331	75	0.7444	65	0.7564	55	0.7693
94	0.7242	84	0.7342	74	0.7456	64	0.7576	54	0.7707
93	0.7251	83	0.7353	73	0.7468	63	0.7588	53	0.7721
92	0.7260	82	0.7364	72	0.7480	62	0.7601	52	0.7735
91	0.7270	81	0.7375	71	0.7492	61	0.7614	51	0.7750
90	0.7280	80	0.7386	70	0.7504	60	0.7627	50	0.7764

According to the same author, 100 measures of water dissolve the following measures of ether of the densities stated: 8 meas. ether, sp. gr. 0.719–0.721; 10 meas. ether, sp. gr. 0.724–0.726; 13 meas. ether, sp. gr. 0.729–0.731; 16 meas. ether, sp. gr. 0.733–0.735; 20 meas. ether, sp. gr. 0.738–0.741; 23 meas. ether, sp. gr. 0.743–0.746; 26 meas. ether, sp. gr. 0.748–0.750.

The purity of the official ethers is determined by their properties, which must agree with those given above.

Pharmaceutical Uses and Preparations.—Ether, or pure ether, is used as a solvent for the removal of inert matter in preparing Digitalinum, Extract. ergotæ liquidum, Ext. stramonii (*Br.*), and Tinct. opii deodorata (*U. S.*); and as a solvent for obtaining Acid. tannicum and the official Oleoresinæ (Extracta ætherea). *U. S.*, *Br.* It is also an ingredient in the different collodions; in Liquor epispasticus (*Br.*); Oleum æthereum (*U. S.*); Spiritus ætheris (*U. S.*, *Br.*); Spir. ætheris compositus, *U. S.*

Physiological Action.—Plants confined in an atmosphere of ethereal vapor lose their irritability, their color, and then their life. Insects are rapidly benumbed, apparently die, and, if the exposure is prolonged, die in reality. In birds and quadrupeds an excited intoxication is followed by oppression of the cerebral functions, anæsthesia with loss of muscular co-ordination, muscular relaxation, and complete insensibility, during which the urine and feces may escape; the capillaries are everywhere distended with blue or venous blood, respiration is suspended, and finally death takes place by arrest of

the heart. In this series of phenomena cerebration is first impaired, then anæsthesia precedes loss of motility, and last of all the movements of the respiratory muscles and those of the heart cease. Indeed, Knoll (1876) inferred from his experiments that the toxic effects of ether are never so intense as those of chloroform, and that it is hardly possible to arrest the heart's action by the direct action of this preparation. Among the effects which, in common with chloroform, it produces may be mentioned rigidity of the thoracic muscles, which, however, is slight and transient if it occurs at all; the period of slow respiration is briefer, and that of hurried respiration never so considerable as in the case of chloroform; and while chloroform may arrest respiration abruptly, ether never has that effect, even when its administration is prolonged. Ether diminishes the pressure against the heart, and lessens the labor of that organ, while chloroform has an opposite effect. The real danger of ether, as proved both experimentally and clinically, lies in its embarrassing the respiration (Arloing, 1879). Again, Newman (1880) found that while chloroform in 75 seconds stops the pulmonary circulation and requires 600 Ccm. of air and 720 seconds to restore it, ten times as much ether is required and only 270 seconds to produce the same effect, which can be removed in 180 seconds by 200 Ccm. of air. To the same purport are Ringer's experiments (1881). Comparing sulphuric ether with chloroform and ethidene, he states that "whilst 1 or 2 minims of chloroform or ethidene dichloride rapidly weaken the heart and arrest the ventricle, even 50 minims of anhydrous ether merely accelerate the beats and weaken them a little" (*Practitioner*, xxvii. 13).

When a compound nerve-trunk is etherized in any part of its course, it loses its sensibility at all points beyond that of the application, although it may retain its motor power, but a prolonged application destroys this also. Introduced into the rectum, especially in the form of vapor, ether produces the same phenomena as when given by the stomach or inhaled. The odor and taste of ether impregnate the flesh of animals for several days after they have inhaled it fully, and in the nervous centres is found a deficiency, and in the liver an excess, of fatty elements.

On man the primary impression of ether, even when smelled, is that of an agreeable nervous stimulant. On the skin it excites coolness if allowed to evaporate, but occasions irritation if confined. When swallowed, it creates burning heat in the throat, œsophagus, and stomach, and a rapid intoxication like that of alcohol, but more intense and of shorter duration. When inhaled, pure ether excites at first cough and dyspœa, and then a pricking of the hands and feet and exhilaration of the spirits, with a peculiar perception of lightness, while the senses all become perverted or blunted: that of touch much less so than the sense of pain, so that severe injuries may be received without their being felt, and brief operations may at this stage be advantageously performed. The muscular system gradually becomes relaxed, while consciousness is growing more perverted or obscured. Meanwhile, the pulse and respiration are generally quickened, the skin becomes warm and moist, and the pupils are contracted, but as complete unconsciousness and anæsthesia supervene, general relaxation is more or less rapidly displayed, the pupils are dilated, the respiration is slow and deep, the pulse infrequent and feeble, the skin cool and moist, and sometimes cyanotic. This state continues only for a few moments after the vapor ceases to be inhaled; consciousness returns almost suddenly, but numbness and weakness remain for some time longer. Dr. Packard has called attention to what he calls the "first insensibility," which is shown by the patient ceasing to repeat a movement he has continued until then to make when directed. This brief insensibility, which lasts from 1 to 3 minutes, may be taken advantage of for the performance of various minor operations, and is not apt to be followed by headache, nausea, etc. It is not accompanied by marked muscular relaxation. Of occasional after-effects of anæsthesia from ether may be mentioned vomiting, congestion of the brain or lungs, various hysterical phenomena, and more rarely epileptiform or tetanoid symptoms, but these effects are exceedingly rare when the ether is pure and skilfully given. The first vomiting, is less usual than after chloroform. The psychical effects of ether are various: sometimes a pugnacious disposition is developed, sometimes an amorous, and even a lascivious, tendency; and again, an irrepressible tendency to say things which under normal circumstances would have been kept profoundly secret, or to use indecorous and even indecent language. Ether drunkenness, like chloral intoxication, numbers a great many victims, most of whom, but for fanatical notions of temperance, would have become the prey of alcohol. It appears to be less permanently injurious than the more usual and brutal vice; for if some deaths are attributed to it, there are instances of its habitual indulgence without serious injury. In the case of a lad addicted to it the usual doses at last amounted to between 1 and 2 pints daily, with-

out apparently impairing his mind (*Boston Med. and Surg. Jour.*, Sept. 1881, p. 262; *Med. Record*, xxiv. 459).

In appropriate cases and properly administered, we believe pure sulphuric ether to be beyond all comparison the safest of the anæsthetic agents employed in general surgery, and that *when these conditions have been observed* there is not a single authenticated example of its having destroyed life. The practical superiority of ether over chloroform is that in cases appropriate for the anæsthetic use of either agent the pulse always gives warning of danger from ether, but in death by chloroform no such signal can be relied on. In 1880 a committee of the British Medical Association presented a report upon anæsthetics, in which the following statements occur: "The danger with ether approaches from the pulmonary rather than the cardiac side, so that by establishing artificial respiration we have a means of warding off death;" and again: "The advantages which chloroform possesses over ether are more than counterbalanced by its additional dangers." In the rare cases which have proved fatal from ether-inhalation the mode of death was precisely the same as that above described in animals destroyed by it: the lungs have become obstructed or the brain congested, while the sustained pulsation of the heart showed a continued capacity of living. In nearly all such cases where an examination has been made after death it has revealed the existence of disease in the kidneys, brain, lungs, or heart, which, had it been known, would have rendered not only the use of an anæsthetic, but even the performance of a grave surgical operation, inexpedient. (Compare *Phila. Med. Times*, xi. 545, 772; *ibid.*, xii. 740; *Med. News*, xl. 295; *Med. Record*, xxiii. 261; *Bull. de thérap.*, ci. 377; *Boston Med. and Surg. Jour.*, Dec. 1883, pp. 560, 568.) Death by chloroform, on the other hand, is nearly always inexplicable by any peculiar condition of the patient, and is the direct effect of the inherent toxic qualities of the anæsthetic. These considerations have doubtless induced a great many physicians in England, Ireland, France, and Germany, as well as in this country, to substitute ether for chloroform in surgical operations.

Medical Uses.—The inhalation of the vapor of ether has in a great measure supplanted its earlier administration in a liquid form, but the latter should not be neglected. It may be given to alleviate nervous *headache* and the pain of flatulent, renal, and hepatic *colic*, spasmodic *vomiting*, including that of *pregnancy* and sea-sickness, and *asthma*, and to prevent or subdue the paroxysms of *hysteria*. Even puerperal *mania* has been held in check by ethereal enemata. It is occasionally indicated as an adjuvant to alcohol in the *typhoid state* of febrile affections, particularly when some temporary exhaustion calls for a transient but vigorous stimulation. Within the last few years ether has been administered hypodermically as a stimulant in cases of exhaustion from *hemorrhage* in the *adynamic* state of fevers (*Bull. et Mém. de la Soc. de thérap.*, 1882, p. 127); but it is not quite clear that its administration by the mouth or the rectum would not have been as efficient. In urgent cases the ordinary hypodermic syringe has been injected, and the operation repeated at intervals of several hours. It would appear that abscesses are very apt to follow this operation. In the treatment of *tape-worm* a full dose of ether to benumb the parasite, so as to facilitate its expulsion by means of castor oil, given directly afterward, is sometimes successful; and so are enemata of ether in destroying *ascarides* of the rectum. Ether has been used for a long time in conjunction with oil of turpentine and also with castor oil with a view of removing *biliary calculi* by dissolving them. The efficacy of the treatment, if real, may depend in part upon the local anæsthetic action of the medicine, but some authorities entitled to respect maintain the reality of its solvent operation also. Whatever view of the mode of action may be entertained, it is certain that ether very frequently removes the symptoms of biliary calculi. The difficulty of digesting cod-liver oil and other forms of fatty food in pulmonary *phthisis* has been supposed to depend upon a deficiency of pancreatic juice and the crude condition in which such food is brought into contact with that secretion. It is claimed that ether, by emulsifying the oil, and also stimulating the stomach and duodenum, and thereby increasing the flow of pancreatic juice, renders the aliment much more assimilable than it would otherwise be. It is also claimed that these views have received the confirmation of experience, and that by the use of ether after taking the food in question it is fully and easily digested, and that the objects of its administration, the increase of the patient's weight and the abatement of the pulmonary symptoms, are secured. The scientific adaptation of the medicine to the purpose in view is very complete, but, like other remedies proposed on similar grounds, and by their proposers regarded as fulfilling their object, this one does not appear to have been found successful. On the contrary, the unpleasant taste of ether, whether given separately or combined with oil, and the offensive eructations to which it

gives rise, render a continued use of it difficult, if not impossible, and evidence is wanting to confirm the results at one time attributed to it.

Besides being taken internally, ether in its liquid form is applied externally to produce anæsthesia or by the cold it occasions in evaporating to cause a contraction of the tissues. With the former object it is familiarly used to relieve the pain of neuralgic headache, and also when applied over the superficial portions of nerves to palliate neuralgia. It affords prompt relief in toothache from carious cavities, especially when associated with camphor, and also in earache when applied on cotton with oil or in the form of vapor. In some cases of deafness due to a rheumatic condition of the auditory canal it is said to have been curative. In irritative congestion of the retina, and photophobia generally, a little ether allowed to evaporate from cotton-wool, so placed in the hollow of the hand as to cover the eye at the distance of an inch or two, affords decided relief. The refrigerant action of ether is best shown in some cases of hernia strangulated by a mere excess of blood in the tumor; it contracts the tissues, expels the blood, and permits the reduction of the bowel. The vomiting of pregnancy, which, as above stated, has sometimes been arrested by the inhalation of ether, is also said to have been subdued "by freezing the pneumogastric nerve under the sterno-mastoid on both sides of the neck alternately" (Lester). A similar application, "first to the epigastrium, and then for 5 minutes on both sides of the throat," is stated to have relieved obstinate hiccup (Regoni). It is claimed that ether spray can arrest the development of malignant pustule and carbuncle (Zimmerlin), and also of tonsillitis (Concato).

Ethereal inhalation is employed to produce anæsthesia, and thereby, according to its degree, to relieve pain, relax muscular tension and spasm, or produce unconsciousness. In surgery it permits the performance of operations which would without it be inexpedient or impracticable, both by abolishing the sense of pain and preventing the struggles of the patient, and hence it has probably diminished the mortality of grave surgical operations. It has been successfully administered for this purpose while the patient remained asleep (*Jour. Am. Med. Assoc.*, i. 244). Age is no contraindication to its use, but it should rarely be employed when there is disease of the kidneys, lungs, brain, or heart, or when the sensations of the patient are needful to guide the surgeon's hand. Operations upon the fauces and nasal passages involving the flow of blood are embarrassed, and may be rendered dangerous, by anæsthesia; it is unfavorable to success whenever the voluntary muscular action of the patient is required; it is unnecessary when the duration of an operation is short or its severity is insignificant. In general, the severer the operation the less danger of accident is there from inhaling ether; the greater number of cases with alarming symptoms have occurred where the operation was trivial, as in extracting teeth, opening abscesses, etc. In obstetrics the inhalation of ether robs the throes of labor of their acutest pain, and hence lessens the exhaustion of the patient; and in tedious and complicated labors, in cases of great tenderness or rigidity of the maternal organs, of unusual susceptibility to pain and great nervous irritability, in labors requiring manual or instrumental interference, and in puerperal convulsions, anæsthesia by ether has long been and continues to be a precious remedy. It does not involve any risk of injury either to child or mother if judiciously employed, while, by lessening the rigidity of the os uteri and perineum without impairing the strength of the expulsive efforts, it facilitates and shortens labor. It is the best palliative for after-pains. For all of the purposes mentioned, except those which involve operations on the interior of the uterus, it is unnecessary to produce the narcotic degree of anæsthesia. It is proper, however, to observe that during childbirth a degree of anæsthesia, by any of the agents employed, may be produced without danger, which, under other circumstances, and especially in surgical operations, might be attended with risk. This peculiar immunity of the parturient woman is probably due to the high nervous tension which her state involves.

The diseases which call for anæsthesia include all painful and spasmodic affections; e. g. neuralgia, dysmenorrhœa, gout in the stomach, biliary and nephritic colic, tetanus, hydrophobia, chorea, hysteria, puerperal and other reflex convulsions, whooping cough, spasmodic croup, laryngismus stridulus, delirium tremens, mania, etc. In all of these it eliminates one or the other, or both, of the symptoms which tend to exhaust the patient. In some local affections of a painful nature, such as lumbago, sciatica, and other forms of neuralgia, the hypodermic use of ether has been employed with advantage. The dose at first should not usually exceed 10 or 15 minims; subsequently it may be increased.

Local anæsthesia may be produced by projecting upon the skin a stream of atomized pure ether or of ether and chloroform. The former is preferable, from the rapidity of its action and the complete congelation it produces, so that a variety of surgical opera-

tions may be performed by its aid without inflicting pain. Among them are not only such minor ones as opening abscesses, the evulsion of nails, the excision of nævi, hæmorrhoids, and other small tumors, and the amputation of fingers, the incision of carbuncles, fistulae, etc., but this method has also been applied to the removal of large tumors of the skin, breast, etc., to amputations, ovariectomy, Cæsarean section, etc. The latter uses indicate rather the extreme limits of its application than its practical utility. Local anæsthesia of the lumbo-sacral region by ethereal vapor has been used to mitigate the throes of labor; of the hypogastric region to arrest uterine hæmorrhage and promote contraction of the uterus; to facilitate the reduction of *hernia* and of *paraphimosis*; to relieve the pain of *neuralgia* by a direct action, and the spasms of *chorea* and other spasmodic affections by its application to the spine. The local use of ether as an anodyne antedates the discovery of anæsthesia by the inhalation of ether.

The hypodermic use of ether has of late (1883) been largely extended. About 1 Ccm. has been generally injected at a time, and the operation repeated as often as necessary. It causes a smarting and burning pain for a short time, but no further ill effects. This method has been found singularly efficient in cases of collapse, however arising, when the patient is unable to swallow; *e. g.* in *cholera*, *typhoid fever*, *pneumonia*, *pulmonary œdema*, *capillary bronchitis*, *infantile and puerperal convulsions*, post-partum and other hæmorrhages, the collapse of *opium- and chloral-poisoning*, etc. It is of interest that the ethereal injections nearly always augment the secretion of urine (Zuelzer, *Centralbl. f. d. g. Therapie*, i. 472). *Sebaceous tumors* of the scalp have been successfully treated by injecting into them with a hypodermic syringe from 5 to 10 drops of ether three or four times, at intervals of several days, until the contents of the cyst were liquefied and its walls inflamed, when the dissolved sebaceous matter and the pus were pressed out (*Bull. de thérap.*, cv. 454).

Administration.—The average dose of sulphuric ether is a fluidrachm (Gm. 4). It may be administered upon powdered sugar and rapidly swallowed with a mouthful of water. Smaller doses may be given by incorporating it with syrup or spermaceti, and diluting the mixture with water or mucilage, which should be made cold by ice if possible. It has also been administered in gelatin capsules. Ether should be administered by some one familiar with it, and who will attend to nothing else. It should not be used while the stomach contains food; no alcoholic drink of any kind should be given to the patient before the operation, nor should he be kept under the influence of the anæsthetic longer than is absolutely necessary. According to Mr. Osborn, chloroformist to St. Thomas's Hospital, London, "Valvular disease of the heart, shown by cardiac murmurs, need be no hindrance to the administration of ether, a fatty heart which is not diagnosable by any auscultatory signs being the form of heart disease which is the most dangerous." Feebleness of pulse also is not a contraindication to the inhalation of ether; indeed, a depressed pulse frequently acquires strength and volume under its influence. It is most conveniently employed by means of a sponge saturated with ether and enclosed in a cone made of a napkin or of coarse paper, large enough to cover the nose and mouth of the patient, and open at the smaller end. Or if the napkin alone be employed, the ether may be poured freely upon its internal surface. The late Dr. Lente held that a capital precept in etherization is to produce anæsthesia as rapidly as possible by overwhelming the patient with as much of the vapor as he can possibly inhale. This method is generally preferred by American surgeons, but Mr. Osborn, above referred to, would apply to all anæsthetics the same law, that the first inhalations of the vapor should be freely diluted with air, for, according to him, large quantities suddenly placed over the patient's mouth and nostrils occasion gasping and struggling for breath. Care must be taken not to allow the contact of flame with the ethereal vapor.

ÆTHER ACETICUS, U. S., Br. Add., P. G.—ACETIC ETHER.

Naphtha aceti.—Acetate of ethyl, E.; *Ether acétique*, *Naphte acétique*, Fr.; *Essigäther*, *Essignaphtha*, G.

Formula $C_2H_5C_2H_3O_2$. Molecular weight 88.

Preparation.—It may be obtained by distilling a mixture of 8 parts of dry acetate of sodium, 5 parts of rectified spirit, and 10 parts of sulphuric acid, adding the distilled product to half its weight of chloride of calcium in a stoppered bottle, letting them remain together for 24 hours, and then decanting and rectifying the ethereal liquid.—*Br. Add.*

The first step in this process is to dehydrate the crystallized acetate of sodium by exposing it to a temperature gradually increased to about 110° C. (230° F.) until it ceases

to lose weight: the water which is thus expelled is nearly 10 per cent. of the weight of the crystallized salt. The remaining operation may be performed in two ways, so that the distillation of the ether may be effected either at once or after some time. If the first is desired, the dry, coarsely-powdered salt is introduced into a retort of sufficient size, which is connected with a good condenser; the alcohol is then added through a funnel-tube inserted in the tubulure, and afterward the sulphuric acid in small quantities. If the latter is added too rapidly, the mixture will become too hot and much alcohol will distil over; should this occur, it is to be returned to the retort. The mixture may then at once be distilled from a water-bath. Or sulphovinic acid may be formed by digesting the mixed sulphuric acid and alcohol in a flask for some time, care being taken to avoid the loss of alcohol; the liquid is then poured upon the sodium acetate contained in the retort; the distillation of acetic ether will commence at once, and should be continued until a dry mass remains behind. This latter process, however, does not appear to be a very desirable one, for W. I. Clark obtained thereby a smaller amount of acetic ether and a greater residuum of secondary products.

A continuous process for its preparation has been devised by J. A. Pabst (1880): 50 Ccm. each of sulphuric acid and strong alcohol are heated in a retort to 140° C. (284° F.), and then a mixture of 1 liter each of 96 per cent. alcohol and 93 per cent. acetic acid is allowed to flow in slowly. At first some ethyl ether comes over; afterward the distillate contains, with considerable uniformity, 85 per cent. of acetic ether. The reaction takes place between 130° and 135° C. (266° and 275° F.). Clark considers this process of no practical value.

Acetic ether was first obtained by Lauraguais (1759) by distilling strong acetic acid with alcohol: the distillate in this case requires to be repeatedly returned into the retort.

The distillate contains, besides acetic ether, water, some alcohol, and acetic acid. To remove the latter, some carbonate of calcium or prepared chalk is added in slight excess and agitated with the liquid until effervescence ceases; acetate of calcium is thus formed, which dissolves in the liquid. Dry chloride of calcium, broken into small pieces and free from alkaline reaction, is now added gradually to prevent the liquid from becoming heated. It will combine with the water, forming a dense solution, which also contains the calcium acetate and nearly all the alcohol of the distillate. After repeated agitation the acetic ether is allowed to separate, when it is removed from the watery liquid and rectified from a clean retort or flask, which is placed in a water-bath kept at a temperature of about 90° C. (194° F.). Clark (1883) ascertained that calcium chloride solution dissolves fully 2 per cent. of its volume of acetic ether; he prefers the removal of water by rectifying the ether over exsiccated sodium acetate.

In the above manipulations sulphovinic acid is first formed (see page 122), 1 molecule of which reacts with 1 molecule of sodium acetate, producing acid sulphate of sodium and acetic ether, according to the equation $\text{C}_2\text{H}_5\text{HSO}_4 + \text{NaC}_2\text{H}_3\text{O}_2 = \text{NaHSO}_4 + \text{C}_2\text{H}_5\text{C}_2\text{H}_3\text{O}_2$ (acetic ether). In Pabst's process the products of the reaction between sulphovinic and acetic acid are sulphuric acid and acetic ether.

The weights of the different ingredients given in the formula of the British Pharmacopœia are very nearly the theoretical proportions. An excess of sodium acetate would cause the distillate to be contaminated with free acetic acid, while an excess of sulphuric acid and alcohol would result in the production of ethyl oxide (ether). Any other acetate in an equivalent proportion may be substituted for the sodium acetate.

In acetic ether the basylous H of acetic acid is replaced by the basylous radical C_2H_5 , forming a compound having the above formula.

Properties and Tests.—Acetic ether is a colorless, limpid, volatile liquid having an agreeable, refreshing ethereal and somewhat acetous odor and taste. The pure ether has a density of .9104 at 0° C. (Kopp), and of .8981 at 15° C. (Mendelejeff; water at 4° C.); the densities given by the Pharmacopœias are: .889 to .897 (*U. S.*), .900 to .904 (*P. G.*), and .910 (*Br.*). The density is no evidence of purity, since acetic ether dissolves ether, alcohol, and chloroform in all proportions, and at 15° C. one-twenty-fourth of its volume of water. It is also soluble in water, requiring of that menstruum at 0° C., 8 volumes, and at 15° C., 9 volumes, or 10 parts by weight (Clark), 11 or 12 parts, *Br.*, about 17 parts, *U. S.* It boils between 74° and 76° C. (165° and 168.8° F.), *P. G.*, at 74.5° C. (166° F.), *Br.*, at about 76° C., *U. S.* It is very inflammable, though less so than ether, and burns with a yellowish-white (bluish-yellow, *U. S.*) flame and the odor of acetic acid vapors. It has a neutral reaction to test-paper, but if kept in contact with the air, and particularly in the presence of water, free acetic acid is formed. Solutions of potassa, soda, and other oxides decompose it gradually or rapidly, if heated, into acetic acid and

alcohol; but metallic sodium does not act upon acetic ether in the cold, except in the presence of water or alcohol (Wanklyn; Ladenburg). It dissolves a little phosphorus and sulphur, and is a good solvent for volatile and fixed oils, many resins, cantharidin, and other organic compounds.

The *purity* of acetic ether is determined by its neutral reaction, its specific gravity, its volatility without residue, and its behavior to water; when 10 Ccm. of it are agitated with an equal volume of water in a graduated tube, the ethereal layer, after its separation, should not measure less than 9 Ccm.—*U. S., P. G.*

Off. Prep.—Spiritus odoratus, Tinctura ferri acetatis, *U. S.*

Physiological Action and Medical Uses.—According to Dr. H. C. Wood, in pigeons and rabbits it produces perfect unconsciousness, without as much previous struggling as when sulphuric ether is used, and has the advantage over that compound of being less inflammable. On the other hand, its volatility is less. On account of its pungency and agreeable odor and its stimulant and antispasmodic qualities it is used for several of the minor purposes of sulphuric ether, and especially to stimulate the nasal passages in cases of *syncope* and *nervous agitation*. Its vapor may also be inhaled under similar circumstances, and to allay *laryngeal* and *bronchial irritation* and *nervous cough*. It may be given internally for the relief of *colic* and *flatulence* in the dose of 30 minims (Gm. 2), or, more properly, diluted. Externally, it may be applied in all the cases in which sulphuric ether is appropriate.

ÆTHER FORMICICUS.—FORMIC ETHER.

Æther formicus.—*Ether formique*, Fr.; *Ameisenäther*, G.

Formula $C_2H_5CHO_2$. Molecular weight 74.

Preparation.—It was first obtained by Bucholz (1782), and is conveniently prepared, according to Kopp, by mixing in a retort 8 parts of dry sodium formiate with 7 parts of alcohol of 88 per cent., and adding 11 parts of strong sulphuric acid. On the addition of the acid enough heat is usually produced to volatilize the ether. The distillate, if acid, is agitated with an equal bulk of water containing lime or magnesia in suspension, and after separation rectified from chloride of calcium.

Properties.—Formic ether is a colorless, thin, inflammable liquid of a strong, agreeable odor somewhat suggesting that of peach-kernels, and a pungent taste. Its density at 17° C. (62.8° F.) is .918; its boiling-point is 55° C. (131° F.). It dissolves in about 9 parts of water, and in all proportions in alcohol, methylic alcohol, ether, fixed and volatile oils.

Physiological Action.—Byasson made experiments with this compound upon dogs, rats, and guinea-pigs. He regarded it as readily undergoing decomposition into alcohol and alkaline formiates through the alkali of the blood. When inhaled, it lowers the temperature as much as 3½° C., induces signs of asphyxia, but not so marked as those caused by chloroform, and causes muscular relaxation and anæsthesia. The effects persist for several hours. Hypodermic injections of Gm. 1–2 in guinea-pigs and rats, and of Gm. 4–6 in dogs, produce a less degree of asphyxia, but more somnolence, lowering of temperature, and a diminution, but not a complete suppression, of sensibility. In man 6 or 8 Gm. occasion no other symptom than drowsiness. The urine contains formic acid.

ÆTHER METHYLICUS.—METHYLIC ETHER.

Oxide of methyl, Hydrate of methylene, E.; *Ether méthylique, Oxyde de méthyl*, Fr.; *Methyläther, Holzäther, Formäther*, G.

Formula $(CH_3)_2O$. Molecular weight 46.

Preparation.—Dumas and Peligot, who discovered this ether in 1835, direct the preparing of it by distilling a mixture of 1 part of methylic alcohol and 4 parts of sulphuric acid, and purifying the gas by prolonged contact with caustic potassa, whereby carbonic and sulphurous acids are removed, and *methyl-sulphuric ether*, which has a garlic-like odor, is decomposed. Kane recommended the purification of the gas by passing it through milk of lime.

Properties.—Methylic ether is a colorless, inflammable gas, heavier than air, of an ethereal odor and aromatic taste. At –36° C. (–32.8° F.) it forms a colorless liquid which boils at –21° C. (–5.8° F.). Water dissolves 35 volumes of the gas, acquiring the odor and taste of the latter, and evolves it again at a moderate heat. It is more

soluble in strong sulphuric acid, and still more freely in wood-spirit, alcohol, and ether. A solution in the latter liquid, saturated at 0° C. (32° F.), has been recommended by Dr. B. W. Richardson under the designation of *methyl-ethyl ether*. It should be kept in well-corked bottles in a cool place.

Physiological Action and Medical Uses.—Being gaseous and only feebly held in solution by alcohol, it is more readily absorbed than this liquid into the blood. Its anæsthetic operation is somewhat peculiar. A pigeon under a bell-glass filled with the vapor of methyl ether, or made to inhale it from a kind of respirator, falls into a quiet sleep without agitation or convulsion. Dr. Richardson, experimenting upon himself, observed that there was no preliminary spasm excited by it in the larynx or elsewhere—no rigidity, lividity, or other change of color. The pulse rose to 96; the anæsthesia was perfect, and was not preceded by convulsion or followed by nausea. In some further experiments (upon guinea-pigs) the anæsthesia was carried as far as possible, and the respiration ceased several minutes before the heart stopped. After death the lungs were not congested, but the pulmonary veins and both sides of the heart were filled with fluid blood, which was dark on the left side. In death by bichloride of methylene the blood in the same cavity is light red. The repletion of the heart contrasts with the emptiness of its cavities in death by chloroform. According to Richardson, it is a safe anæsthetic, yet is objectionable because it rapidly volatilizes from its solution, and its odor is more unpleasant than that of ether, chloroform, or bichloride of methylene.

ÆTHYLENI BICHLORIDUM.—BICHLORIDE OF ETHYLENE.

Æthylum chloratum, Elaylum chloratum, Liquor Hollandicus.—*Ethene chloride, Dutch liquid, E.; Liqueur des Hollandais, Huile du gas oléfiant, F.; Æthylenchlorid, Elayt-chlorid, G.*

Formula $C_2H_4Cl_2$ or $CH_2Cl.CH_2Cl$. Molecular weight 98.8.

Preparation.—Olefiant gas and Dutch liquid were discovered by Dieman, Troostwyk, Bondt, and Lauwernburgh (1795). The latter is produced on bringing the former in contact with chlorine gas. 1 part of strong alcohol is mixed with 3 or 4 parts of sulphuric acid and sufficient sand to form a thick mixture, which is heated, and the gas passed successively through sulphuric acid, solution of potassa, and sulphuric acid, whereby it is deprived of alcohol, ether, and sulphurous and carbonic acids. The gas thus purified is conducted into a retort containing a mixture of 2 parts of black oxide of manganese, 3 of common salt, 4 of water, and 5 of sulphuric acid. The retort is at first very moderately warmed, and afterward heated until the liquid distils. The distillate is washed with water and rectified over chloride of calcium.

Properties.—It is a colorless, thin, oily liquid, having an ethereal odor resembling that of chloroform, and a sweetish ethereal taste; it has the specific gravity 1.27 at 0° C. (32° F.) or 1.253 at 15° C. (59° F.), boils at 85° C. (185° F.), is sparingly soluble in water and freely soluble in alcohol and ether. It is inflammable, and burns with a yellowish flame having a green border, and giving off vapors containing hydrochloric acid. When agitated with water the latter does not acquire an acid reaction to litmus-paper, and when agitated with sulphuric acid the mixture is not blackened. On being mixed with alcoholic solution of potassa, water and potassium chloride are formed, and gaseous *chloroethylene*, $CH_2.CHCl$, is given off at a moderate temperature; this gas condenses at $-18^{\circ}C.$ ($-4^{\circ}F.$).

Allied Compounds.—By the action of chlorine upon Dutch liquid a number of chlorinated compounds may be obtained, which are isomeric with the chlorinated compounds produced under similar circumstances from *chloride of ethyl, chlorethane*, or, as it is frequently termed, *muriatic (hydrochloric) ether*.

CHLORIDE OF ETHYL, C_2H_5Cl or $CH_3.CH_2Cl$ (molecular weight 64.4), is obtained by passing dry hydrochloric acid gas into cold strong alcohol, distilling at a very moderate heat, washing the distillate with water and a weak alkaline solution, and rectifying. It is a thin, colorless, inflammable liquid, having an ethereal odor and a sweetish aromatic afterward somewhat alliaceous taste. It dissolves in about 50 parts of water, boils at 12.5° C. (53.6° F.), and at 0° C. (32° F.) has the density .9214. If chlorine, not in excess, acts upon it,

MONOCHLORINATED HYDROCHLORIC ETHER (ethylidene chloride, ethylene chloride), $C_2H_4Cl_2$ or $CH_3.CHCl_2$, is produced. It is isomeric with bichloride of ethylene, which it resembles in odor, but its density is only 1.198; it boils at 57.5° C. (135.5° F.), is decomposed by strong sulphuric acid, and when heated with alcoholic solution of potassa distils almost without change.

On continuing the action of chlorine, the following isomeric compounds are obtained from

Ethyl chloride.

$C_2H_5Cl_3$. Sp. gr. 1.372; boiling-point $75^{\circ}C$. ($167^{\circ}F$).
 $C_2H_5Cl_4$. " 1.530; " " $127.5^{\circ}C$. ($261.5^{\circ}F$).
 C_2HCl_5 . " 1.644; " " $158^{\circ}C$. ($316.4^{\circ}F$).
 C_2Cl_6 . Prisms; fuse at $160^{\circ}C$. ($320^{\circ}F$), boil at $182^{\circ}C$. ($360^{\circ}F$); odor aromatic, camphoraceous.

Ethylene chloride.

Sp. gr. 1.442; boiling-point $115^{\circ}C$. ($239^{\circ}F$).
 " 1.576; " " $147^{\circ}C$. ($296.6^{\circ}F$).
 " 1.663; " " $158^{\circ}C$. ($316.4^{\circ}F$).

Physiological Action and Medical Uses.—When bichloride of ethylene was tested by Simpson, he found that although it was capable of producing anæsthesia without excitement of the pulse or subsequent headache, yet it caused so great irritation of the throat that few persons could persevere in breathing it long enough to induce the anæsthetic state. Other experimenters have reached the same conclusions, but it is generally agreed that the liquid does not tend to induce the dangerous collapse which constitutes the chief objection to chloroform. This conclusion has been fully sustained by the experiments of Dr. Reichert (*Phila. Med. Times*, xi. 492), which prove that death from this agent invariably takes place from failure of the respiration, and not from any direct action upon the heart. In regard to its administration, Dr. Reichert insists that while it does possess irritant properties, and does cause distress when first inhaled, the distress is not much, if any, worse than that caused by the inhalation of ether. As a local anæsthetic this preparation has been applied to the seat of pain in *neuralgia* and other limited painful parts, such as exist in *cancer*, etc. The dose required to produce anæsthesia is about the same as that of chloroform.

Chloride of ethyl, formerly known as muriatic or hydrochloric ether, appears to be almost identical in its primary effects with sulphuric ether, but they are more transient and are less apt to be followed by nausea. Its extreme volatility, however, renders it unmanageable in practice, and even dangerous if used near a flame. It is sometimes dissolved in an equal bulk of alcohol, and dispensed as alcoholic muriatic ether for the same purposes to which Hoffmann's anodyne is applied. It may be given in the dose of from 10 to 30 drops (Gm. 0.60–2.00) in sweetened water or in a little wine or spirit and water.

Ethydene chloride was employed by a committee of the British Medical Association in six experiments. Its odor is agreeable, it produces rapid narcosis without much previous excitement, and its use is rarely followed by nausea and vomiting. It appears to render the pulse more, and then less, frequent. In from 8 to 12 minutes complete anæsthesia and muscular relaxation are produced, the respiration going on regularly but slowly, the pulse being full and slow. There is neither pallor nor blueness of the face. Such results were also obtained by Bird (*Times and Gaz.*, Jan. 1879, p. 62) in patients operated upon for diseases of the eye. The phenomena were those occasioned by a strong stimulant of the heart's action, and the reporter's only apprehension was lest, "if it always proved such a stimulant," the reaction might be excessive. But Ringer declares, without qualification, that "ethyden dichloride affects the ventricle just like chloroform" (*Practitioner*, xxvii. 13). If this declaration refers to degree as well as to kind, it is discordant with the statements just made, and also with the latest results obtained by the committee of the British Association, among which the following are included: vomiting is occasioned by ethyden as well as by chloroform, but is more persistent after chloroform; with both the pulse falls as the respirations increase, but with chloroform the effect is both more frequent and more marked, and chloroform retards the heart-beats more, and oftener produces dirotism; chloroform and ethyden reduce the blood-pressure in animals, but chloroform more rapidly, irregularly, and to a greater degree; in no single experiment with ethyden was there an absolute cessation of the heart's action or of respiration; as regards comparative danger to life, chloroform stands first, then ethyden, and lastly ether (*Amer. Jour. of Med. Sci.*, Apr. 1881, p. 555). The final judgment of the same committee is, that ethyden is free from the disadvantages of ether and the dangers of chloroform. The use of this anæsthetic by Macphail in minor surgical operations led him to analogous conclusions (*Edin. Med. Jour.*, xxv. 220).

Clinical experience with ethyden has quite reversed the judgment concerning it based almost exclusively upon physiological experiments. Reichert finds a record of about 3000 administrations with a list of 3 deaths, and 4 cases in which the most alarming symptoms ensued. In all of these cases, except one of which no details are given, death took place by failure of the heart. He also states that ethyden was abandoned by Snow on account of its danger, and that it is probably more dangerous than chloroform, notwithstanding the views entertained of its physiological action (*Med. News*, xl. 206). As lately as 1883 a death from it occurred in England during a very slight surgical operation (*Phila. Med. Times*, xiii. 420). It is administered by pouring the liquid on a piece of lint placed in a tumbler, which is held over the mouth and nose, or by "Jun-

ker's apparatus," employed for inhaling chloroform. From 1 drachm to an ounce (Gm. 4-30) has been employed in several operations.

ÆTHYL BROMIDUM.—BROMIDE OF ÆTHYL.

Æther hydrobromicus.—*Hydrobromic ether*, E.; *Bromure d'éthyle*, *Æther hydrobromique* (*bromhydrique*), Fr.; *Bromäthyl*, *Bromwasserstoffäther*, G.

Formula C_2H_5Br . Molecular weight 108.8.

Preparation.—Serullas (1827), the discoverer of this ether, recommended its preparation by the action of bromine upon alcohol in the presence of phosphorus. Personne (1861) replaced the latter by amorphous phosphorus. Prof. Remington (1877) suggested the following modification of Personne's process: 33 parts by weight of absolute alcohol are introduced into a flask or retort, which is placed in ice; when thoroughly cooled, 6 parts of amorphous phosphorus are added, and afterward 26 parts of bromine dropped in, with the precaution of avoiding too great an elevation of temperature. The mixture is allowed to stand 24 hours, and then distilled; the distillate is washed with water and, if acid, with a little alkali, and finally rectified over chloride of calcium. The residue in the retort is phosphorous acid, or phosphoric acid and phosphorus; the reaction is analogous to that produced in preparing hydriodic ether. Dr. W. H. Greene (1879) found the following process to work satisfactorily: 12 parts of coarsely-powdered potassium bromide, and 11 parts of sulphuric acid diluted with its bulk of water, are heated in a flask; when hydrobromic acid begins to be disengaged, 12 parts of alcohol are allowed to flow in slowly; the distillate requires washing with water and alkaline carbonate before rectification.

Properties.—Bromide of ethyl is a colorless, very volatile liquid of a strong ethereal odor and a sweetish and warm taste. It has the density 1.419 at 15° C. (59° F.), boils at 40.7° C. (105.2° F.), burns with some difficulty with a green, non-sooty flame, is sparingly soluble in water, and dissolves in all proportions in alcohol and ether.

History.—In 1849, Nunnelly not only tested the anæsthetic virtues of this compound upon animals, but used it in various surgical operations, and claimed for it a superiority over chloroform. But the supreme authority of Simpson maintained the use of the latter, and caused the bromide to be forgotten by the medical profession in general. But in 1865, Nunnelly brought the subject before the British Medical Association, and stated that for 1 year he had performed all the operations in the Leeds Eye Infirmary with the assistance of this ether. But he failed to make any impression upon his audience. In 1876, Rabuteau made some experiments upon animals with bromide of ethyl, and in the following year it was used experimentally and clinically by Dr. Turnbull of Philadelphia, when it was taken up by Dr. Levis and others and applied to the graver operations of surgery.

Physiological Action.—*On Animals*: The earliest experiments with bromide of ethyl were made by Nunnelly. He introduced a cat into a jar containing a drachm of the liquid. The animal immediately showed signs of insensibility; the respiration grew slower and then ceased. Its lungs were found collapsed, the pulmonary veins full, the bronchial mucous membrane pale; the right side of the heart and the large veins were distended with blood; the left ventricle was contracted and empty; the vessels of the meninges were filled with blood. This experiment was repeated by Dr. Turnbull with identical effects, except that he found the kidneys very much congested. The lungs were bloodless, and the right side of the heart was "distended with ante-mortem clots." The experiments of Wolff gave essentially the same results. Dr. H. C. Wood also concluded from his experiments that "the bromide of ethyl acts as a cardiac paraly sant," and that "its action is more analogous to that of chloroform than of ether, and therefore partakes of the dangerous qualities of the former"—conclusions which were fully corroborated by Reichert, who also proved that it at times acts altogether out of proportion to the dose used (*Amer. Jour. of Med. Sci.*, July, 1881, p. 54). The only dissentient from these conclusions was also a physiological experimenter, who compared the action of this bromide to that of nitrous oxide, from which it really differs *toto calo*. More recently, Sidney Ringer found that it "arrests the ventricle, and must, therefore, act on the muscular substance of the heart. . . . Like sulphuric ether, it accelerates its beats" (*Practitioner*, xxvii. 17).

On Man: The taste of this liquid is rather sweet and pleasant, but it is irritating to mucous surfaces. Internally, in doses of from 5 to 30 drops, well diluted, it produces only a slight drowsiness, and, inhaled, it is represented as "the most agreeable and rapid

anæsthetic yet brought before the medical profession." Similar virtues were attributed to it by Dr. Levis, to whom its vogue as a surgical anæsthetic was chiefly due. According to Turnbull, its advantages are a rapid elimination by the lungs and an "increase of pulse and respiration." In 1880 he pronounced it safe when used with care, claiming that the heart and respiration are but slightly affected by it unless it is employed in excessive quantities, and that it is rapidly eliminated by the kidneys, as well as by the lungs; he dwelt upon the advantages due to its agreeable odor, its non-inflammability, its slight tendency to cause vomiting or headache, salivation, or bronchial flux, as compared with chloroform or ether, and noted the rapidity with which its effects pass off (*Trans. Amer. Med. Assoc.*, xxxi. 261). It is true that some surgeons, like Prof. Agnew, found it even more liable than chloroform to cause vomiting (*Phila. Med. Times*, x. 372). This tendency was also noted by Terillon, almost the only European physician who seems to have used the compound. Describing its anæsthetic properties, he says that "it causes relaxation rapidly, without asphyxia and without excitement, if largely administered from the first. During the anæsthetic stage, unlike chloroform, it causes suffusion of the face and neck, frequency of the pulse, and dilatation of the pupils; consciousness returns promptly. On the whole, although it seems to require a less careful supervision than chloroform, yet it certainly ought not to be used by unskilful hands" (*Bullet. de thérap.*, xcviii. 402). Terillon expressly states that he witnessed no tendency to suspension of the heart's action, and only apprehended danger from respiratory embarrassment. Some reporters have declared that its action upon the circulation is similar to that of ether, and that it causes increased frequency and strength of the pulse. One assures us that no greater toxic effects are produced upon the system than would result from the administration of ether or alcohol (*Med. Record*, xviii. 67). The frequency of the pulse under its use has also been pointed out by Reeve (*Med. News*, xlii. 317).

Deplorable experience has shown how erroneous were all such judgments. Several cases of death occurred under the administration of this agent so much lauded for its superior safety, and many other cases in which death was certainly imminent. In the fatal cases the result was usually due to syncope, but in one of them did not take place for several days, and then by exhaustion from vomiting. In the cases that did not terminate fatally the phenomena were usually those of cardiac syncope or of obstruction. In one instance pleasant intoxication, excitement, and spasm were followed by sleep, and then by a sudden cessation of the pulse (*Med. Record*, xvii. 554). In another the pulse suddenly failed, the face grew cyanotic, the respiratory movements imperceptible, the eyes upturned and fixed, the jaws locked, and the whole body stiffened (*Phila. Med. Times*, x. 430). In a third case the head was jerked back and spasms affected all the muscles, the breathing was rapid, and the pulse small (*Med. Record*, xvii. 469).

It appears probable that bromide of ethyl may be dangerous in two ways: first, as a compound, and then by its decomposition in the body. In the former of these modes of action it resembles chloroform, and destroys life by arresting the heart. The possibility of the latter operation has been suggested by Dr. Squibb (*Trans. Amer. Med. Assoc.*, xxxi. 285), who pointed out that the danger from anæsthetics is in proportion to the noxiousness of their radicals. Those which are the most readily tolerated are so in proportion to the simplicity and innocuousness of the elements of which they are composed. Bromine is an irritant poison, and bromide of ethyl is very easily decomposed, and its 73 per cent. of bromine, an active irritant, is disseminated through the system. According to Squibb, chloroform, although it contains 89 per cent. of chlorine, does not produce as toxic effects as ethyl bromide, simply because 2 atoms of chlorine are not as poisonous as 1 atom of bromine. The danger from either anæsthetic is by no means passed when consciousness returns; the chlorine in the one case and the bromine in the other remains behind, and may still induce grave and even fatal effects. In some cases the remote phenomena are distinctly those of irritant poisons. In corroboration of the last statement may be quoted Reichert's reference to Nunnelly's experiments with ethylene dibromide and ethyl iodide, in which the animals appeared perfectly well after the experiments, but after some hours perished from blood-poisoning (*Am. Jour. of Med. Sci.*, July, 1881, p. 556).

Uses.—When first introduced, this anæsthetic was cordially welcomed by many surgeons as being more agreeable and prompt than ether and less dangerous than chloroform; and one of its leading but still cautious advocates declared that his "continued experience with it in the surgery of a large general hospital and in private practice impressed him with the conviction that it is the best anæsthetic known to the profession" (*Phila. Med. Times*, x. 247). The disasters that followed soon after this and similar declarations seem

to have discouraged its advocates and led to its disuse in general surgery. Even in *parturition*, for which it was declared peculiarly adapted, it did not find acceptance, although it continues to be used by some accoucheurs (*Med. News*, xlii. 329); but in *epilepsy*, *hysteria*, and *angina pectoris*, for which it at first was employed, it has almost ceased to be recommended as a remedy. As a local anæsthetic, applied with a hand-atomizer, it was used by Terillon in operations for opening *abscesses*, removing *vegetations*, in *fistula* and in forcible dilatation of the *anus*, flexion of *anchylosed joints*, etc.

Administration.—Bromide of ethyl may be administered in the same manner as sulphuric ether and chloroform. Those most active in promoting its use urged that unless the first portions “were crowded on the patient” it was not apt to act promptly; one also said, “I prefer always to make a rapid and decided impression with the lint and napkin held closely over the nose and mouth of the patient.” After it became known that its mode of action, and therefore its dangers, are of the same kind as those of chloroform, such advice would hardly have been given. The quantity used has varied from 1 fluidrachm in short and trivial operations to 11 fluidrachms in an operation of 40 minutes’ duration. The same precautions should be used as in the case of other anæsthetics relating to repletion of the stomach, the position of the patient, his breathing deeply, preventing pressure on his neck or chest. Quite as important, if not more so, is it that the surgeon should be certified by a competent physician that the patient is not affected with any organic disease tending to increase his risk. It has happened that, for want of such a precaution, patients have been allowed to take this agent or chloroform while laboring under disease of the brain or lungs or a convulsive disorder. In using it to produce a local anæsthesia the orifice of the atomizer should be large and not nearer than about 3 inches from the skin, and the spray should not be very fine. About 3 minutes are required to produce congelation.

ÆTHYL IODIDUM.—IODIDE OF ETHYL.

Æther hydriodicus, *Hydriodic ether*, E.; *Iodure d’éthyle*, *Ether hydriodique*, Fr.; *Jod-äthyl*, *Jodwasserstoffäther*, G.

Formula C_2H_5I . Molecular weight 156.

Preparation.—This compound was prepared by its discoverer, Gay-Lussac (1815), by distilling a mixture of absolute alcohol and concentrated hydriodic acid, and separating the ether from the distillate by means of water. Much better results are obtained by distilling a mixture of alcohol, phosphorus, and iodine, as proposed by Serullas (1827); and the substitution of amorphous for ordinary phosphorus, first used by Personne (1861), affords still greater advantages. Reith and Beilstein (1863) obtained the best results by macerating for 24 hours a mixture of 10 parts of amorphous phosphorus, 50 parts of alcohol, specific gravity .83, and 100 parts of iodine, the latter added in small quantities; the mixture is then distilled, the distillate decolorized by a little solution of soda, and freed from water by rectification over chloride of calcium. The residue in the retort from the first distillation consists of phosphoric acid, the reaction occurring according to the following equation: $5I_2 + P_2 + 10C_2H_6O$ yields $10C_2H_5I + 2H_3PO_4 + 2H_2O$.

Properties.—Iodide of ethyl is a colorless, non-inflammable liquid having a peculiar penetrating odor. It is freely soluble in alcohol, nearly insoluble in water, does not react upon litmus, boils near $72^\circ C.$ ($161.6^\circ F.$), and has at $15^\circ C.$ ($59^\circ F.$) the specific gravity 1.93. Exposed to air and light, it liberates iodine, and is gradually colored red and brown; the presence of metallic mercury, or preferably silver, prevents the coloration, but not the decomposition. Iodine is also liberated by chlorine gas, nitric acid, and strong sulphuric acid.

Medical Action and Uses.—More than 30 years ago (1849), Nunnally reported as a result of experiment that three out of four animals were rendered insensible by this preparation, and all of them died. He even declared that, although the animals were not made insensible, the effect of the inhalation was generally fatal. For these reasons, probably, the use of the compound was for a long time suspended, and, as it now appears, unnecessarily. Iodide of ethyl has been used by inhalation to bring the system speedily under the influence of iodine, and especially in chronic *bronchitis* and pulmonary *phthisis*. It doubtless contributes to diminish the bronchial secretions. But its more demonstrable and useful property consists in its rendering the act of breathing deeper and easier, while it exhilarates somewhat, but has no soporific or anæsthetic effect, nor does it depress any of the functions. Of the different forms of *dyspnoea* in which it gives more or less relief, spasmodic *asthma* is the one which it most relieves (Lawrence, *Med. Record*, xvii.

688; xxiii. 58). If the iodine contained in the compound has a share in its action, it is probably a subordinate one. It has been used with benefit in chronic *laryngitis*. 10 or 15 drops (Gm. 0.60–1.00) may be inhaled several times a day from a handkerchief or an appropriate respirator.

AGARICUS ALBUS.—WHITE AGARIC.

Fungus laricis, *Boletus laricis*.—*Purging agaric*, E.; *Agaric blanc*, *Agaric purgatif*, Fr.; *Lärchenschwamm*, G.

Polyporus officinalis, *Fries*, s. *Boletus laricis*, *Jacquin*, s. *B. purgans*, *Persoon*.

Nat. Ord.—*Fungi*, *Polyporei*.

Origin.—This fungus grows on old trunks of the European larch in Central and Southern Europe, and on *Larix sibirica*, *Ledebour*, in the northern section of Asia, whence it is brought into commerce. It is without a stalk, hoof-shaped or irregularly conical, 4 to 8 inches (10–20 Cm.) broad, 2 to 4 inches (5–10 Cm.) thick, and sometimes 8 to 12 inches (20–30 Cm.) high, externally grayish or yellowish; the hymenium on the lower side is in the form of small yellowish pores. It is collected in autumn and winter, and deprived of the firm outer rind.

Description.—Agaric occurs in commerce in irregular pieces of the size of a fist, and frequently much larger. It is white, light, somewhat spongy, very friable, but not readily pulverizable, has a faint odor and a sweetish afterward acrid and lastingly bitter taste.

Substitution.—We have noticed (1875) a white insipid fungus, mixed with powdered agaric to impart a bitter taste, sold in place of the medicinal drug. The substitute appeared to be a species of *Agaricus*, with a lamellate hymenium, the greater part of which had been removed. Another occasional substitute, according to Wiggers, is the cap of *Polyporus ignarius* dusted over with the powder of white agaric.

Constituents.—White agaric has been analyzed by Bucholz (1808), Bouillon-Lagrange, Trommsdorff, and Bley (1834); the boletic acid of the latter, according to Bolley and Dessaignes (1853), is identical with *fumaric acid*, and Braconnot's *fungic acid* was ascertained by them to be a mixture of citric and malic acids. Fumaric acid has also been found in several other fungi. Martius and Will (1846) separated *laricin*, $C_{14}H_{48}O_2$, in the form of a white, amorphous, bitter powder, soluble in alcohol and oil of turpentine and forming a jelly with hot water. Fleury (1870) obtained *agaric acid*, which crystallizes in needles, is freely soluble in strong alcohol, less so in ether, and is almost insoluble in water. On exhausting agaric with boiling alcohol, Masing (1870) observed the separation, on cooling, of a slowly crystallizing fusible body, which dissolves readily in alkalis but is less soluble in alcohol than agaric acid. The same author denies the presence of benzoic acid, observed by Bouillon-Lagrange; by the process of the latter he obtained an amorphous resin. The resins were further examined by Masing (1875); two are sparingly soluble in cold alcohol and crystallizable; one of these is soluble in chloroform, has a faintly bitter taste, and melts at 125° C. (257° F.); the other is sparingly soluble in chloroform, and melts at 90° C. (194° F.). The resin soluble in cold alcohol is a mixture of two resins, brownish-red, intensely bitter and readily soluble in chloroform, glacial acetic acid, benzol, and amyl alcohol. Many fungi contain mannit, others mycose; which of the two is present in agaric has not been ascertained.

Medical Action and Uses.—The ancients used agaric as a purgative in large doses and as an astringent in small doses. In the former way, and owing probably to its resin, it is said to have produced watery stools and colic, with nausea and vomiting in some cases; and in the latter it was employed to check *diarrhoea* and restrain *sweating*. It is for the last-mentioned purposes that it is now occasionally used, as well as to diminish excessive *bronchial secretion*. These three indications are often associated in pulmonary consumption, and it undoubtedly is one of the best palliatives that can be used of the symptoms mentioned. Murrell (*Practitioner*, xxix. 321) traces its use to De Haen in 1767, who learned it from an old woman. From that time it has been employed successfully to check colliquative sweating, and in pulmonary phthisis it also palliates the cough and promotes sleep, perhaps indirectly. It is said also to hasten the drying up of the *milk* in weaning. Agaric may be given in pill, in the dose of 2 or 3 grains (Gm. 0.12–0.20), and repeated hourly or less frequently, according to the urgency of the case. Wolfenden (*Times and Gaz.*, Oct. 1881, p. 442) recommends 20-grain doses of powdered agaric, but owing to its dryness, lightness, and bitterness it is taken with difficulty in this form. Murrell gave pills made of the extract, each pill of 3 grains being equivalent to

9 grains of the powder. A tincture and a fluid extract have also been found efficient. The active principle, agaricine, has been prescribed in doses of one-twelfth of a grain (Gm. 0.005). Prepared agaric is useful as an application to leech-bites and similar wounds to arrest hæmorrhage, and formed into cylinders it serves for moxas.

AGAVE.—AMERICAN ALOE.

Century-plant, E.; *Maguey*, E., Fr.; *Agave*, G.

Agave americana, Linné.

Nat. Ord.—Amaryllidaceæ.

Description.—The plant is indigenous to the tropical portion of America, has been introduced and naturalized in Southern Florida, and is frequently met with in cultivation in all parts of the globe, and to some extent naturalized in the warmer portions thereof. The leaves are all radical, curving backward, about 6 feet (5.4 M.) long, thick and fleshy, lanceolate in shape, and at the apex and margins armed with sharp spines. The plant flowers in its native localities usually in about 10 years, but attains a considerable age before flowering in temperate climates, hence the name “century-plant;” the rapidly-growing flowering scape reaches a height of 30 to 40 feet (9–12 M.).

Agave mexicana, Lamarck, and *A. vivipara*, Linné, are closely-allied Mexican species.

Uses.—A translucent gum is obtained from it, known as *gum-maguey*, which is partly soluble in water, the solution containing malate of calcium, besides a substance resembling arabin. The fibres of the leaves, known as *pita*, are strong and valuable for cordage. The juice of the plant, *aguamiel*, or honey-water, is saccharine, and is either evaporated to the consistence of honey, or more frequently fermented to yield a vinous acidulous beverage, which in Mexico is called *pulqué*, and by distillation a kind of brandy known as *mezcal* or *aguardiente de maguey*. The roots are regarded as possessing alterative properties. (For papers on the uses of *Agave* the reader is referred to *Amer. Journ. Pharm.*, 1875, p. 78, and 1876, p. 301.)

Agave virginica, Linné, of the Southern United States, produces a scape about 4 or 5 feet (1.2–1.5 M.) high. Its roots are very bitter.

Medical Action and Uses.—The fresh juice of this plant is acidulous or acrid, and is said to be laxative and diuretic. A nearly-allied species furnishes a juice from which, as above stated, the Mexican alcoholic drink *pulqué* is prepared; and in the Southern States of this country a tincture is made from the roots of *A. Virginica*, and used for the relief of *colic* and as an antidote to the *rattlesnake's bite*. This plant is known as the *rattlesnake's master*.

AGRIMONIA.—AGRIMONY.

Herba agrimonie.—*Aigremoine*, *Eupatoire des Grecs*, Fr.; *Odermennig*, *Leberklette*, G.

Agrimonia Eupatoria, Linné.

Nat. Ord.—Rosaceæ, Roseæ.

Description.—An herbaceous perennial, about 2 feet (60 Cm.) high, indigenous to Europe and North America, and growing along roadsides and the border of woods. The root is fibrous, several-headed, and brown; the stem almost simple; the leaves about 5 inches (13 Cm.) long below, pinnate, with 4 to 8 pairs of elliptic-oblong, coarsely-toothed leaflets, intermixed with several pairs of minute ones; the stipules semi-cordate, clasping, and coarsely serrate. The yellow flowers are rather small, in slender spicate racemes, and have a persistent top-shaped calyx, which is covered with hooked bristles. The plant is collected while flowering from June to September and deprived of the coarse stems. It has a very faint aromatic odor and a bitterish, mildly astringent taste, which is stronger in the root.

The closely-allied *Agr. parviflora*, Aiton, indigenous to the United States, is distinguished by smaller flowers and by crowded lanceolate leaflets, of which there are 11 to 19 pairs, intermixed with smaller ones.

Constituents.—H. K. Bowman (1869) determined agrimony to contain 4.75 per cent. of tannin; the other constituents are unknown.

Medical Action and Uses.—Common agrimony is astringent and stimulant, and is chiefly employed in popular medicine in gargles for *sore throat*, as a wash for *ulcers* in man and beast, and internally for the cure of *intermittent fever*, *chronic fluxes* of the bowels, bladder, vagina, etc., and for passive *hæmorrhages*. It is said to be used instead of Chinese tea by the peasantry of the north of France. It may be given in an infusion made with from 1 to 4 drachms (Gm. 4–16) in a pint of water. Externally, it may be

employed in fomentations, poultices, injections, or gargles, and in the latter form with the addition of honey, vinegar, borax, or chlorate of potassium. According to Nicholson, it is an efficient *tenuicide* when given pounded to a pulp and followed several hours afterward by a dose of jalap, and also an active diuretic and *antiscorbutic* (*Times and Gaz.*, Sept. 1879, p. 367).

AILANTHUS.—TREE OF HEAVEN.

Chinese sumach, E.; *Götterbaum*, G.

Nat. Ord.—Simarubaceæ.

Description.—Three species are medicinally employed, of which two are natives of India, and one, indigenous to China, is much cultivated in the United States and Europe as an ornamental tree. The latter is *Ailanthus glandulosa*, *Desfontaines*. It is of rapid growth, producing a straight trunk, which is covered with a nearly smooth, brown-gray, internally yellowish, fibrous bark. The leaves are 3 or 4 feet (.9–1.2 M.) long, oddly pinnate, with about 15 pairs of leaflets, which are shortly petiolate, oblong or ovate-lanceolate, with a few teeth near the base. The greenish polygamous flowers are in terminal panicles, and exhale an odor which is disagreeable to many persons. The pistillate flowers produce 3 to 5 linear-oblong, one-seeded samaras. This tree is known in France as *vernix des japon*, which name is also used for *Rhus Vernix*, *Linné*.

The leaves are the favorite food of the silk-worm, *Bombyx cynthia*; the barks of the trunk and of the root have been employed medicinally; both have a persistently bitter taste.

AIL. EXCELSA, *Roxburgh*, is a similar tree, with larger and broader leaflets. The bark, which is used as a tonic and febrifuge in India, is of a reddish or orange color internally, and has a very bitter taste.

AIL. MALABARICA, *De Candolle*, has obliquely oblong and entire leaflets and obtusely winged fruits. When incised the bark yields a gum-resin which has an aromatic odor and is used as incense in India and medicinally in dysentery.

Constituents.—An analysis by Alonzo Lilly (1861) of the bark of the first species determined the presence of tannin and a trace of volatile oil, besides the widely-distributed vegetable principles; the bitter principle was not isolated. The bark of the second species was analyzed by Marayan Daji (1870), who found the bitter taste to be due to the calcium salt of *ailanthic acid*, which like the lead salt is yellow and soluble in water. The acid is uncrystallizable, freely soluble in water, insoluble in other solvents, of a waxy consistence and reddish-brown color.

Medical Action and Uses.—The infusion, decoction, and tincture of the bark are stated (Daji) to be useful in *anorexia*, *dyspepsia*, and atonic conditions generally of the digestive organs, such as those for which gentian, quassia, etc. are prescribed. The acid is said to provoke the secretion of bile when it is deficient. An infusion of the leaves has been employed in *dysentery*. *Ailanthus* has been used in the treatment of *tenia* in dogs, and also in man, under the form of a powder of the bark or leaves, and also as a watery or an alcoholic extract of the bark, a resin, and an oleo-resin. It has caused the expulsion of the parasite when given in substance in the dose of 8 grains (Gm. 0.50) or 4 grains (Gm. 0.25) of the watery extract, or 3 grains (Gm. 0.20) of the oleo-resin. The resin alone is nearly inert. The extract occasions slight colic and moderate purging, and does not exhaust or depress like pomegranate or kousso.

ALBUMEN OVI, *Br.*—EGG ALBUMEN.

White of egg, E.; *Blanc d'œuf*, Fr.; *Eiweiss*, G.

The liquid white of the egg of *Gallus Bankiva*, var. *domesticus*, *Temminck*. (See VITELLUS.)

Medical Uses.—It forms insoluble and inert compounds with corrosive sublimate and sulphate of copper, and is therefore a convenient and efficient antidote in *poisoning* by these substances. Agitated with powdered alum, it coagulates, and thus forms a convenient and very grateful poultice for local *erythemas*, *burns*, *contusions*, *excoriations*, *bites* and *stings* of insects, etc.; and confined in a thin bag, it is a popular and useful application for acute inflammations of the *conjunctiva*. Diluted with water or added to milk, it forms a valuable article of food in the *diarrhoeal* complaints of children and adults. It is an appropriate article of food in albuminuria.

ALCOHOL, U. S.—ALCOHOL.

Spiritus, P. G.; *Spiritus rectificatus*, Br.; *Spiritus vini rectificatissimus*, *Alcohol vini*.—*Rectified spirit*, E.; *Alcool*, Fr.; *Weingeist*, *Alkohol*, G.

Spirit of the specific gravity 0.820 U. S., 0.838 Br., 0.830 to 0.834 P. G. Containing per cent., by weight, of absolute alcohol 91 U. S., 84 Br., 87.2 to 85.6 P. G. Containing per cent., by measure, of absolute alcohol 94 U. S., 88.7 Br., 91.2 to 90 P. G.

Diluted alcohol has the specific gravity 0.928 U. S., 0.920 Br., 0.892 to 0.896 P. G. Contains per cent., by weight, of absolute alcohol 45.5 U. S., 49.2 Br., 61.5 to 59.8 P. G. Contains per cent., by volume, of absolute alcohol 53.2 U. S., 57 Br., 69.1 to 67.5 P. G.

Formula of absolute alcohol, C_2H_5HO . Molecular weight 46.

Origin.—Alcohol may be obtained synthetically by first preparing acetylene, C_2H_2 , by direct union of its elements, converting this into ethene, C_2H_4 , and by combination with the elements of water forming alcohol. It has been detected by Dr. Gutzeit (1875) in the juice of a number of plants; Béchamp (1880) proved its presence in the urine and in the muscles of animals, and in putrid meat; and Muentz (1882) showed it to be contained in minute quantities in air, river-water, and cultivated soil. It is extensively prepared by the fermentation of saccharine liquids.

Fermentation.—Although the knowledge of various fermented alcoholic liquids dates back to remote antiquity, alcohol does not appear to have been separated from the spirituous beverages until about the eighth century of the present era, and soon afterward its strength was increased by repeated distillation. Under the name of *fermentation* various processes of decomposition are embraced, apparently depending upon the mere presence of a certain substance or compound, called the *ferment*, which does not enter into chemical composition with the fermenting substance or its products, and is capable of producing a large, if not unlimited, quantity of the latter. The several varieties of fermentation are distinguished from each other by the products obtained. Accordingly, we speak of *saccharine* fermentation when starch is converted into dextrin and sugar by diastase; of *lactic* fermentation when milk-sugar is transformed into lactic acid by casein; of *butyric* fermentation when milk-sugar and lactic acid yield butyric acid in the presence of the same compound; of *muic* fermentation when cane-sugar is changed into mucus and mannit by protein compounds; of *alcoholic* or *vinous* fermentation when grape-sugar, or fruit-sugar, is split into alcohol and carbonic acid under the influence of yeast; and of *acetic* fermentation when alcohol is oxidized to acetic acid, for which process some investigators consider the appearance of *Mycoderma aceti* as a ferment necessary. The decomposition of the numerous class of organic compounds known as glucosides by the action of emulsin, myrosin, and similar protein compounds, and the action of ptyalin upon starch, of pancreatin upon fat, and of pepsin upon albumen, etc., are other instances of fermentation induced and completed by the substances named, which are the ferments.

The exact manner in which these ferments act has not yet been determined, and with respect even to the vinous fermentation is still a subject of controversy, notwithstanding the numerous experiments performed with the view of solving the problem. When, in 1810, Gay-Lussac demonstrated that sugar solutions would ferment only in the presence of atmospheric air, the process was regarded as depending upon the action of oxygen. Although the presence of organisms in yeast was afterward demonstrated (see FERMENTUM), their connection with the process itself was not ascertained. Liebig (1839) perfected and enlarged the theory which was advanced by Stahl during the preceding century, and regarded fermentation as a metamorphosis induced by nitrogenized substances in a state of decomposition or putrefaction. Chiefly through Pasteur's investigations, which have been continued since 1858, it is now generally conceded that under ordinary circumstances the ferment of alcoholic fermentation is of vegetable origin, and consists of the so-called yeast-cells or yeast-plant, *Saccharomyces* (*Torula*, *Turpin*) *cerevisiæ*, *Meyen*, the sporules of which are widely diffused in the air, and are thus easily supplied to all liquids capable of vinous fermentation; hence, if these spores are destroyed by boiling the liquid, and if their further supply is arrested by admitting only air which has been filtered or passed through sulphuric acid, vinous fermentation does not take place. Alcohol and the other compounds formed during fermentation are not merely regarded as decomposition-products of sugar, but they result from the growth and multiplication of the yeast-plant, the existence of which depends upon the presence of sugar and protein, and by whose cells the new compounds are generated.

The formation of alcohol from sugar is expressed by the equation $C_6H_{12}O_6$ (grape-sugar) $= 2CO_2 + 2C_2H_5O$ (alcohol); but the process does not appear to be so simple,

since small quantities of succinic acid (about 0.6 per cent.), glycerin (3 per cent.), and cellulose (1 per cent.) are always formed, according to Pasteur. Amylic and other homologous alcohols are likewise produced in vinous fermentation.

Berthelot observed that mannit, glycerin, milk-sugar, and other carbohydrates yield alcohol very slowly when in contact with water, chalk, and casein.

Preparation.—Cane-sugar is not directly fermentable until after it has been inverted, either by the action of a ferment or of a diluted acid. (See SACCHARUM.) Nearly all the ordinary alcohol is obtained from starchy substances, such as corn, rye, potatoes, etc., which require to be *mashed*, during which process, by the gluten contained in grain or by the diastase of the malt added with this object in view, the starch is converted into *maltose* (see AMYLUM), and finally completely changed into dextrose, or grape-sugar, when it becomes fermentable. This being accomplished, fermentation will speedily set in on the addition of yeast if the temperature is kept at 22° C. (71.6° F.) or within the limits of 18° and 28° C. (64.4° and 82.4° F.). At a lower temperature fermentation proceeds slowly, and at a higher temperature mucilage and lactic acid are apt to be formed. If too large a quantity of sugar is present, the fermentation will be arrested after some time, in consequence of the destruction of the vitality of the yeast-plant by the alcohol formed. A very favorable proportion is 1 part of sugar to 4 of water. It is obvious that grape-sugar or fruit-sugar, from whatever source obtained, may be used in the manufacture of alcohol.

On subjecting the fermented liquid to distillation a weak spirit is obtained, which requires rectification and contains small quantities of homologous alcohols or ethers, varying with the source from which the spirit has been obtained. *Potato spirit* contains amylic alcohol; *whiskey*, obtained from grain, contains, besides amylic alcohol, some cœnanthic and other ethers; *brandy*, the distillate of wine, owes its odor to cœnanthic and perhaps propylic and allied ethers; *rum*, from fermented molasses, to butyric ether; and *arrack*, from fermented rice, to an unknown compound. The odor of *gin* is imparted by distilling spirit with juniper-berries; that of the so-called *kirsch*, or *kirschwasser*, by the seeds of cherries or plums added before fermentation: in this case it is due to hydrocyanic acid and oil of bitter almonds.

The *purification* of spirit is effected by percolating it through recently burned and granulated charcoal, by which the fusel oil is retained; this process is called *leaching*, and is most effectually accomplished if the spirit has been previously diluted. Distillation with various chemicals, with the view of destroying the fusel oil, has been suggested, and small quantities of manganates and permanganates have been used with success (manganate of sodium for Atwood's alcohol). A small quantity of nitrate of silver (not more than from 2 to 5 Gm. for 1000 liters of crude spirit) has been recommended for the same purpose; the silver may obviously be recovered without difficulty. Usually, however, the purification and concentration of the spirit are effected in one operation by distilling it and passing the vapors through a series of condensers kept at different temperatures, or through an upright column, in the lower part of which the fusel oil and water are condensed at a temperature at which the alcohol is not liquefied, but this is recovered subsequently in an ordinary condenser. The apparatus is constructed so as to permit an uninterrupted distillation until the water finally has accumulated in the still.

Naudin (1882) has devised a process by means of which the odorous compounds, particularly the aldehyds, are changed into alcohols through nascent hydrogen, generated by electrolysis.

The last traces of foreign odor are difficult to remove by re-rectification, but are said to be completely separated by pure sodium acetate, on distilling the alcohol over about 2 per cent. or less of this salt which has been previously deprived of water by fusion.

The spirit, as obtained by the different processes of distillation, contains water, the first distillate being stronger, the later portions weaker, in alcohol; the strongest spirit obtainable from an ordinary still with a single condenser has the specific gravity 0.825; with a system of condensers alcohol of the density 0.815 to 0.817 is obtainable. The last portions of water can be removed only by treating the alcohol with a substance having great affinity for water, for which purpose chloride of calcium and other deliquescent salts, anhydrous sulphate of copper, burned lime, etc., have been proposed. If chloride of calcium is used, the distillation must be slow and repeated two or three times. Lime is better adapted for the purpose if broken into pieces and digested with the alcohol for a day or two, or boiled with it for an hour, previous to distillation. The distillate, the first part of which is weaker than the subsequent portions, contains lime which has been mechanically carried over, and will be left in the retort if the alcohol is again rectified

with the addition of a little tartaric acid. (For some practical observations on the rectification of alcohol by means of lime the reader is referred to the *Amer. Journ. of Pharmacy*, 1872, p. 111, and 1874, p. 184.)

ALCOHOL DILUTUM, U. S.; Spiritus tenuior, *Br.*; Spiritus dilutus, *s.* Spiritus vini rectificatus, *P. G.*—Diluted Alcohol, Proof spirit, *E.*; Alcool dilué, *Fr.*; Verdünnter Spiritus, *G.*

Alcohol 50 parts (11 fluidounces); Distilled Water 50 parts (9 fluidounces), to make 100 parts (nearly 19½ fluidounces). Diluted alcohol of this strength may be prepared from alcohol of any higher percentage by the following rule, in which all terms denote weight: Divide the alcoholic percentage of the alcohol to be diluted by 45.5, and subtract 1 from the quotient. This gives the number of parts of water to be added to 1 part of the alcohol.—*U. S.*

Take of rectified Spirit 5 pints; Distilled Water 3 pints. Mix.—*Br.* Alcohol 7 parts; Distilled Water 3 parts.—*P. G.*

Properties.—Spirit containing 50 per cent. *by volume* of absolute alcohol and water, and having the specific gravity 0.936 at 15.55° C. (60° F.), has been adopted as the standard *proof spirit* of the United States custom-house and internal revenue service. The terms *second proof* (52½ per cent. alcohol, spec. grav. 0.931), *third proof* (55½ per cent., spec. grav. 0.925), and *fourth proof* (58 per cent., spec. grav. 0.920), are at present less frequently used than formerly. The British proof spirit has the specific gravity 0.920 (.9198), and contains 49.24 per cent. *by weight* of absolute alcohol. Spirits stronger than this standard are lighter, and are said to be *over proof*; they are 20 over proof if 100 measures require to be diluted with water to 120 measures to become reduced to proof strength. 100 measures of rectified spirit, sp. gr. .838, when mixed with 60 measures of water yield 156 measures of proof spirit; rectified spirit is therefore said to be 56 per cent. over proof. A spirit which is weaker than the standard is heavier, and is said to be *under proof*; it is 20 under proof if 100 measures require the addition of alcohol sp. gr. .825 (the strongest obtainable by simple distillation) to make 120 measures of proof spirit.

When alcohol is mixed with water an elevation of the temperature is observed, and the mixture assumes for a short time an opalescent appearance from the dissolved air, which is expelled in numerous minute bubbles, after which it becomes perfectly transparent; when it has cooled to the ordinary temperature the volume will be found diminished. This contraction is greatest on mixing 55 measures of absolute alcohol with 45 measures of water, which will yield 96.23 measures of weaker alcohol, showing a loss of volume equal to 3.77 per cent.

The strength of alcoholic liquids is conveniently determined by their specific gravities. A modification of the hydrometer, called the *alcoholometer*, has been constructed by which the percentage strength by volume or by weight may be directly ascertained. As the density increases appreciably with a diminution of temperature, and decreases in about the same ratio with an elevation of temperature, alcoholometers are constructed with reference to a standard temperature, which is either 15° C. or 60° F.; every degree of variation indicates a difference of .36 for the former and .25 for the latter scale, which must be added if the alcohol tested was below, or subtracted if it was above, the standard temperature.

In the United States and Germany the scale of Tralles, and in France that of Gay-Lussac, are in use. Both instruments are practically identical; they sink in distilled water to 0 and in absolute alcohol to 100, each intervening division indicating a volumetric percentum of absolute alcohol. Richter's alcoholometer is essentially that of Tralles combined with a scale indicating also the percentage by weight of absolute alcohol. The alcoholometer employed in the British revenue system is that of Sykes; its stem is divided into 10 parts, but by means of nine accurately adjusted weights which may be attached to the lower part of the instrument the scale is practically very considerably extended; the indications thus obtained are by means of tables converted into the percentage strength over proof or under proof.

In the following table we give the percentage of alcohol by volume and weight for each division of Tralles's scale, together with the specific gravity; also the density indicated by Gay-Lussac's alcoholometer at the corresponding degree. It will be observed that the absolute alcohol of this scale really contains 99.9 per cent. of absolute alcohol—a difference which is too insignificant for all practical purposes; but it should be remembered that the specific gravity for Tralles's scale is given for 15.55° C. (60° F.), compared with water at 3.9° C. (39° F.), while that of Gay-Lussac's scale applies to 15° C. (59° F.) for both alcohol and water:

A very useful table for the reduction of alcohol (*U. S. P.*) has been published by Dr. A. B. Lyons in 1882. It gives the *measures* of official alcohol and water required for obtaining 100 measures of the mixture at 15.55° C. (60° F.) and the specific gravity of this mixture at the same temperature; incidentally, the table gives also the amount of condensation. We omit the percentage-strength, which is readily ascertained from the preceding tables :

Sp. gravity of mixture.	For 100 measures use		Sp. gravity of mixture.	For 100 measures use		Sp. gravity of mixture.	For 100 measures use	
	Alcohol, U. S. P.	Water.		Alcohol, U. S. P.	Water.		Alcohol, U. S. P.	Water.

1. **ABSOLUTE ALCOHOL.**—This is a colorless, limpid liquid, which does not congeal, but acquires an oily consistence when cooled to -90° C. (-130° F.). It has a refreshing odor and a very pungent taste, a burning impression being produced upon the palate by the union with water, for which it has great avidity. Its specific gravity at 15.55° C. (60° F.) is 0.7938, and it boils at 78.3° C. (174° F.) (Mendelejeff). It has a neutral reaction to test-paper, and does not cause anhydrous sulphate of copper to assume a blue color when left in contact with it (absence of water). It dissolves iodine, bromine, a little phosphorus and sulphur, the alkalies and alkaline earths, the chlorides, iodides, and nitrates of many metals, many organic acids, and nearly all alkaloids, resins, volatile oils, camphor, and fixed oils. With water and ether it unites in all proportions without becoming turbid. It is entirely volatilized by heat, is readily inflammable, and burns with a non-luminous blue flame and without smoke, yielding carbonic acid gas and water. Commercial absolute alcohol generally contains a minute quantity of water, to detect which Debrunner (1879) proposed crystallized permanganate of potassium, which he found to be totally insoluble in anhydrous alcohol, but to impart a red tinge to it in the presence of .05 per cent. of water.

2. **ALCOHOL** of the present Pharmacopœia is the *Stronger alcohol* of the Pharmacopœia of 1870. It has all the properties of absolute alcohol except the specific gravity, which is .820 at 15.6° C. (60° F.) and .812 at 25° C. (77° F.), and it contains 9 per cent. by weight of water, the presence of which is shown by the tests mentioned above. Castor oil is freely soluble in it, but most of the other fixed oils dissolve only to a limited extent. It boils at 78.2° C. (172.4° F.).

Alcohol *Br.* has the density .838, and dissolves a smaller quantity of castor oil, oil of turpentine, various resins, and other compounds than the preceding.

For use in the arts and for various laboratory purposes *methyiated spirit* is not subject to taxation in Great Britain. It is a mixture of 90 per cent. of alcohol and 10 per cent. of wood-spirit or methylic alcohol, which addition renders it unfit for internal administration.

3. **DILUTED ALCOHOL** of the different Pharmacopœias varies in density between .892

(*P. G.*), .920 (*Br.*), and .928 (*U. S.*). Its solvent powers for iodine, most of the alkaloids, the volatile oils, resins, and fixed oils are inferior to those of alcohol. Its freedom from impurities is ascertained in the same manner as for a stronger spirit; its boiling-point is 82°C . (179.6°F .).

The French Codex gives for every preparation the volumetric strength of the alcohol to be employed.

Composition.—Alcohol has the empirical formula $\text{C}_2\text{H}_6\text{O}$, and is the hydrate of the univalent radical *ethyl*, C_2H_5 ; its rational formula is therefore $\text{C}_2\text{H}_5\text{HO}$. It is the most common, and may be regarded as the type, of a homologous series of alcohols which are distinguished by prefixing the name of the radical contained in them; hence, *ethylic* or *ethyl alcohol* for the alcohol under consideration. Under the influence of oxidizing agents the alcohols first part with 2 atoms of hydrogen, being converted into *aldehyds*, and by combining afterward with 1 atom of oxygen are converted into a monobasic acid—in this case *acetic acid*. The ethers derived from these alcohols contain 1 molecule of the radical in place of the single atom of hydrogen in the above formula; the following will explain this relation:

Ethyl. C_2H_5	Ethyl oxide (ether). $(\text{C}_2\text{H}_5)_2\text{O}$	Ethyl hydrate (alcohol). $\text{C}_2\text{H}_5\text{HO}$	Aldehyd. $\text{C}_2\text{H}_4\text{O}$	Acid (acetic). $\text{C}_2\text{H}_4\text{O}_2$
----------------------------------	--	---	--	--

Tests.—The purity of the different official alcohols is determined by their odor, specific gravity, miscibility with water, complete volatility, neutral reaction, and their behavior to nitrate of silver. If a portion of at least 50 Ccm. be evaporated to dryness in a glass vessel, no residue or color should appear. If mixed with its own volume of water and one-fifth its volume of glycerin, a piece of blotting-paper, on being wet with the mixture, after the vapor of alcohol has wholly disappeared should give no irritating or foreign odor (fusel oil). And if a portion be evaporated to one-fifth its volume, the residue should not turn reddish upon the addition of an equal volume of sulphuric acid (amyl alcohol). When treated in a test-tube with an equal volume of solution of potassa there should not be an immediate darkening of the liquid (methyl alcohol, aldehyd, and oak tamin). If a portion of about 150 Ccm. be digested for an hour with 20 Gm. of carbonate of lead and filtered, the filtrate then distilled from a water-bath, and the first 20 Ccm. of the distillate treated with 1 Ccm. of test solution of permanganate of potassium, the color should not disappear within 1 or 2 minutes (absence of methyl alcohol). If 20 Ccm. are shaken in a glass-stoppered vial, previously well rinsed with the same alcohol, with 2 Ccm. of test solution of nitrate of silver, the mixture should not be rendered more than faintly opalescent during 1 day's exposure to direct sunlight (absence of more than traces of foreign organic matters, fusel oil, etc.).—*U. S.*

Potassium permanganate is also readily decolorized by aldehyd and many other organic compounds. Fusel oil is readily detected by adding 10 drops of potassa solution to 50 Gm. of the alcohol, evaporating in a water-bath to about 5 Gm., and acidulating with sulphuric acid, when the odor of fusel oil will be plainly observed. Marquardt (1882) proposed to dilute the alcohol to about .980, agitate with pure chloroform, and evaporate the chloroformic solution spontaneously, when the residue, treated with oxidizing agents, will give the odor of valerician acid; by combining this with baryta the fusel oil may be determined quantitatively.

Pharmaceutical Uses and Preparation.—Alcohol is employed on account of its solvent properties in the manufacture of alkaloids and other proximate principles, of resins, numerous extracts, some plasters and chemicals, and is a permanent ingredient of all tinctures, spirits, most fluid extracts, some mixtures, liniments, solutions, a few infusions, syrups, wines, etc.

Physiological Action.—Alcohol applied to the roots or the stems of plants destroys their life. It is poisonous to every animal, producing local or general anæsthesia according to the mode of its employment. Applied to the trunk of a nerve, it paralyzes all of its branches, and to the brain, it impairs sensation and voluntary motion. Injected into the veins in a concentrated state, it coagulates the blood, and diluted it causes intoxication. The latter effect is seen in all animals that have taken alcohol into the stomach, and, according to the dose, it produces excitement, stupor, or death. Leven found that while excessive doses of alcohol given to dogs arrested digestion and inflamed the stomach, moderate portions of it exerted a "powerful digestive action" (*Times and Gaz.*, Feb. 1880, p. 245). After death the stomach is more or less injected, the vessels of the brain are congested, and those of the portal system have been found to contain alcohol. The gastric and the intestinal mucous membranes are injected and softened,

and so is the tissue of the liver, which organ is also enlarged. The lungs, heart, and kidneys are loaded with dark blood. When animals are kept for a long time intoxicated they present the same characteristics as human drunkards. The chief difference is, that after a short experience their instinct impels them to refuse the poison which the intelligence of man does not prevent his craving although it destroy him.

In man the local action of alcohol produces cold if the liquid can evaporate, but irritation if it cannot escape. Applied to a raw surface, it excites a severe smarting pain and coagulates the blood. Taken internally in small quantities appropriately diluted, it excites a sense of warmth in the stomach, and, if the person is very susceptible, an almost instantaneous glow throughout the body, flushing of the skin, with increased frequency and force of the heart and pulse, a livelier flow of ideas, which are, according to the temperament of the individual, gay or gloomy, and disposes to actions which in like manner may be playful or malevolent. In larger and intoxicating doses alcohol occasions such symptoms for a short time, but speedily induces a state of impaired perception and motor power, which is followed by one of total insensibility and unconsciousness, in which the phenomena are those of congestion of the brain and usually of the whole capillary vascular system, although the latter sometimes gives way to coldness and pallor. In this condition death has frequently occurred after an excessive draught of distilled liquor. Some of these phenomena appear to be due to a paralysis of the capillaries which favors the venous congestion of the brain, lungs, and other organs, and some to the direct poisonous action of the alcohol on the nerve-centres. After death the blood in some cases has furnished alcohol or some of its derivatives, aldehyd particularly, by distillation (*Boston Med. and Surg. Jour.*, Sept. 1880, p. 223). In two cases, occurring the one in Germany and the other in this country, the victims were about five years old: the one swallowed half a tumblerful of brandy, the other of whiskey; both had convulsions with opisthotonos, and one died in 12 and the other in 18 hours. The insensibility to pain of drunken persons is well known. We recall the case of a man who was brought into the hospital during an exciting political election in a state of intense alcoholic excitement. He had a fracture of the arm about the upper third, and yet he whirled this limb violently around his head, hurrahing for his favorite candidate, without the slightest expression of pain. He made an excellent recovery. Habitual excesses, according to the form and quantity of the alcohol consumed, tend to increase fat and diminish muscular tissue, and to render the capillary blood-vessels everywhere turgid, giving to the skin, especially of the face, a puffy and purplish look. The digestion becomes impaired, the nervous system unsteady, the gait loses its elasticity, the hands grow tremulous, the senses dull, and the mind torpid; the sleep is broken, dreamy, and unrefreshing. After unusual excesses delirium tremens is apt to occur, and habitual drunkenness, sooner or later, in many cases induces a state of chronic imbecility, with partial paralysis. Fatty heart, cirrhotic liver, and granular kidneys are frequently associated lesions, producing fatal dropsy, especially if distilled liquors have been employed, while gout is a more usual result of intemperance in wine.

Experiments and observations made to determine the mode of action of alcohol in the economy have too generally referred to excessive doses rather than to such as are employed in dietetics and in medicine. Hence a dispute has arisen whether alcohol raises or depresses the animal temperature, when it is of daily experience that moderate doses augment the heat and excessive doses diminish it. In febrile disease it is quite possible that the dose which in health would have been excessive, and even destructive of life, may, by limiting heat-production, tend to preserve the tissues upon which life depends. If, as is altogether probable, this effect is due to a power in alcohol of stimulating the exhausted nervous system, and thereby exciting the distended capillary blood-vessels to contract, it is evident that less blood will reach the tissues, that less heat will be developed, and less waste of tissue result. This diminished waste is represented by the smaller amount of carbonic acid exhaled from the lungs and of urea secreted by the kidneys. The special effect of alcohol in a given case depends upon its dose and upon the time during which it has been operating. The primary effect may be stimulating, and be indicated by an increased activity of cerebration; it corresponds to the turbulence and throbbing noted by Dr. M. P. Jacobi in her experiments in a case of exposed brain; but the secondary effect is the very opposite of this, and is accompanied by passive venous congestion. It is probable that alcohol reduces febrile temperature partly by lessening the oxidizing power of the red corpuscles. The use of alcohol in every age and by every nation in the world demonstrates that it satisfies a natural instinct, that it literally refreshes the system exhausted by physical or mental labor, and that it not only

quickens the appetite for food and aids in its digestion, but that it spares the digestive organs by limiting the amount of solid food which would otherwise be required. But in accomplishing this salutary end it does not act as a mere condiment. It is also food—in this sense at least, that it offers itself in the blood as a substitute for the tissues which would otherwise be destroyed. "Alcohol," says Moleschott, "is the savings bank of the tissues. He who eats little and drinks alcohol in moderation retains as much in his blood and tissues as he who eats more and drinks no alcohol." It is certain that of any amount of alcohol ingested not in excess of what the system requires only a minute fraction can be recovered from any of the secretions; the remainder undergoes metamorphosis and is eliminated in a new form. The notion that alcohol is unassimilable, and is chiefly eliminated through the lungs, rested upon the familiar fact that all alcoholic beverages contain ethereal elements which are so eliminated, and thus infect the breath. But it results from the careful observations and experiments of Anstie, Binz, and others that alcohol is not exhaled by the lungs or skin or excreted with the urine unless the body be supersaturated with it. In that case it may be found in the blood, in exhaled serum, etc. According to some experimenters, a portion of alcohol in the blood is transformed into acetic acid, which forms acetates that are subsequently decomposed into water and carbonic acid. The doctrine that alcohol is food is probably true, not only indirectly by preventing tissue-waste, but in the more literal sense of its favoring the formation of fatty products, especially by increasing the amount of adipose tissue, and in a morbid sense by tending to produce fatty liver and kidney, gall-stones, and atheroma. All of these conclusions have been so amply confirmed by a continuous succession of observers and experimenters as to leave no doubt of their correctness.

Medical Uses.—In the form of wine or distilled spirits alcohol is the universal and familiar remedy for *debility* of every kind, whether it be due to exhaustion produced by *shock*, *fatigue*, or *prolonged sickness*, or shown by *syncope* arising from a nervously feeble or an exhausted heart, to wasting chronic disease, or to the tissue-destruction of acute febrile affections. In *typhus fever* and the *typhoid state* of numerous diseases, including *pyæmia*, the usefulness and appropriateness of the medicine are demonstrated, not only by its diminishing the frequency and increasing the strength of the pulse, and by the decline of the symptoms which denote capillary stasis, but also by the very large quantities of it which may be taken without producing intoxicating effects. This tolerance may be added to the facts already stated to confirm the doctrine that alcohol is consumed in the body and subserves the purposes of food. The special conditions which call for the use of alcohol, and without which, or some of which, it is apt to be injurious rather than useful, are the following: constitutional *debility*, and especially that which is due to advanced life; a compressible, slow, or irregular *pulse*, with a feeble impulse and first sound of the *heart*; a tendency to *syncope*; a sluggish capillary circulation and a *dry tongue*; wandering *delirium*, *stupor*, *tremor*, or *subsultus*, and involuntary dejections. In the fevers above mentioned there are both loss of power and nervous disorder (adynamia and ataxia); in some other diseases there is adynamia alone, or, as it is more specifically termed, *asthenia*—diseases in which the spinal nervous system appears exhausted, and debility and even paralysis of the muscles, both voluntary and involuntary, may occur. These accidents happen in the fevers already mentioned, and also, but less frequently, in the *eruptive fevers*, in *relapsing fever*, and in *diphtheria*, in all of which the first threatening of their approach should be met with alcoholic and other stimulants. It should always, in acute febrile disease, be administered in divided doses and its effect upon the symptoms noted. If it moderates such as have been enumerated, it may be regarded as useful, and may be continued in doses varied by its effects. The essential point in its administration is that it shall never be allowed to produce intoxication, even by abnormally exciting, and still less by stupefying. It is absolutely contraindicated in febrile diseases with scanty and albuminous urine of low specific gravity.

The same rule should govern the use of alcohol in *pulmonary consumption*. If it improves digestion, increases the weight and strength, reduces the fever, and lessens the cough, expectoration, and sweating, it may be regarded as exerting its most favorable influence. But, unfortunately, these salutary effects cannot be confidently anticipated; too often it increases fever, diminishes appetite, and impairs digestion. Two conditions appear to be essential to its utility: first, that the phthisis shall be primary and chronic, and not the consequence of a previous pleurisy or lobar pneumonia; and secondly, that the patient shall use muscular exercise in the open air proportioned to his strength. Under these circumstances it is the best adjuvant of cod-liver oil, which, indeed, so far as alcohol is a nutrient, it resembles in its mode of action. In *delirium tremens* alcohol in

the form of malt liquor, wine, or distilled liquor is a direct antidote to this peculiar effect of intemperance. As the morning drom steadies the tremulous hand and tottering gait of the sot, so alcohol reduces to co-ordination the distracted ideas, perceptions, and movements of the victim of delirium tremens, and the more certainly, speedily, and with a smaller dose in proportion as it is aided in its operation by physical fatigue produced by walking. It must not be forgotten that this delirium is usually the result of an abrupt cessation of the habit of drinking, either by the stomach giving out or by some suddenly depressing influence, such as a surgical injury. In poisoning by venomous *serpents* and by *narcotics* alcohol is often used to sustain life until the elimination of the poison has been accomplished. In some cases of the former kind very large doses of alcohol have been tolerated—whether owing to the poison itself or the patient's excitement may be questioned. The full effects of this liquid have proved sufficient for the cure of *traumatic tetanus*; its slightly stimulant action, on the other hand, has been resorted to for preventing *epileptiform* attacks, and by the same mechanism doubtless it prevents, and even arrests, reflex *convulsions*, such as occur during *dentition*, the *vomiting of pregnancy*, and the paroxysms of *neuralgia*, when thus administered in small doses.

As an external application alcohol, either in its natural or its distilled form, has always been used as a dressing for *wounds*. The ancient use of oil and wine for this purpose is well known. In the seventeenth and eighteenth centuries alcohol was applied as a dressing to incised and other clean wounds, and also to those attacked with gangrene. Recent observations attest its excellence in arresting hæmorrhage, coagulating the albumen of exuded plasma, preventing the putrefaction of discharges, and promoting cicatrization. In 1870, Dr. Blair, a Scottish physician, published an account of the use of strong whiskey as a popular dressing for wounds among his countrymen, and of his having then recently seen it employed in the Parisian hospitals (*Glasgow Med. Jour.*, ii. 204). From 1872, Perrin employed alcoholic dressings, and proclaimed their superiority in compound and comminuted fractures, especially when complicated with contusion of the soft parts, also in wounds of whatever kind which tended to putrefaction, and held them to be more efficient, as well as more convenient, than carbolic-acid dressings. He found that alcohol protected such injuries from gangrene, excessive suppuration, and usually from erysipelas, while they rapidly acquired a healthy aspect and the traumatic fever accompanying them was slight. He gave the preference to alcohol over all other applications as a dressing for surgical wounds, including amputations (*Bull. de thérap.*, xvi. 308). In 1874, and again in 1880 and 1882, the whiskey dressing was highly recommended by Suesseroth (*Phila. Med. Times*, ii. 774; xi. 138; xii. 872); and in 1882, Gosselin used diluted alcohol to promote the cure of abscesses. Having been opened by a small incision, they were evacuated as far as possible, and washed out with alcohol, and also dressed with it. The purulent discharge rapidly became serous, the abscess contracted, and healed more rapidly than by any other method (*Times and Gaz.*, March, 1882, p. 311). In dressing wounds, after removing foreign substances and clotted blood, the part is bathed with the alcoholic liquid and covered with compresses saturated with the same and protected by some impermeable covering. It should be kept moist with the liquor for several days, during which it should, if possible, remain undisturbed. Afterward the dressing may be changed daily or less frequently, according to circumstances. It is an efficient dressing for atonic *ulcers* and *gangrenous* lesions, tends to prevent and heal fissure of the *nipples* and excoriation of the *feet* by walking, and is the best of all applications to recent *bruises* and *sprains* and superficial inflammations, and as a vehicle for other agents fitted for this purpose and for stimulating *paralyzed limbs*. Alcohol has been used to remove *polypi* of the nostrils and of the middle and external ear. It does so by abstracting the water of which they largely consist and coagulating their albumen. In the case of the ear the auditory canal should be filled with the liquid two or three times a day, allowing it to remain in place from 5 to 15 minutes. It has been injected into angiomatous and other soft tumors to cure them by hardening them (*Virch. Arch.*, lxxxv. 172). The anæsthetic power of alcohol has long been known, as exhibited by the greater or less insensibility of intoxicated persons who meet with accident, and of women who unconsciously give birth to children while drunk. It was even employed to diminish the shock of *surgical operations* and to facilitate the reduction of *dislocations*. It was formerly the custom before operations to administer a draught of alcohol and laudanum; and even since the introduction of anæsthetics it has often been found that their depressing effects are in this manner prevented, while their soporific action is more decided and occurs more promptly (Mason, *Jour. of Inebriety*, Oct. 1882).

In the treatment of alcoholic poisoning the stomach should first be emptied by means

of a mustard emetic, administered by the stomach-pump if necessary. Cold water may be dashed against the breast and spine and applied to the head, while various mechanical expedients are employed to keep the patient awake. In some cases, even of dead-drunk-ness, a few drops of water of ammonia instilled into the throat or held under the patient's nostrils will suffice to dissipate the stupor.

ALCOHOL AMYLICUM, Br.—AMYLIC ALCOHOL.

Fusel oil, Amyl alcohol, Pentyl alcohol, E.; Alcool amylique, Huile de grain, Fr.; Amyl-alkohol, Fuselöl, G.

Formula $C_5H_{11}HO$. Molecular weight 88.

A peculiar alcohol obtained from fermented grain or potatoes by continuing the process of distillation after the ordinary spirit has ceased to come over.

Preparation.—During the alcoholic fermentation of grain and potatoes some amylic alcohol is produced, the great bulk of which passes over with the last portions of the first distillation, which are milky, and contain besides amylic some ethylic alcohol and water, and variable quantities of propyl alcohol, isobutyl alcohol, and other compounds, differing from the source of the fusel oil. The portion remaining in solution with the distilled spirit is obtained in purifying the latter, either by the process of distillation or leaching. (See ALCOHOL.) Commercial amylic alcohol contains variable quantities (between 20 and 30 per cent.) of ordinary (ethylic) alcohol, of which it cannot readily be completely deprived by fractional distillation and washing with water. Distillation over chloride of calcium, after previous washing with water, removes most of this alcohol, a portion of which will, however, again pass over with the distillate. An effectual and economical method has been proposed by B. Hirsch (1861), who advises crude amylic alcohol to be repeatedly agitated with concentrated aqueous solutions of table-salt until a diminution of its volume is no longer noticed; it still contains a little alcohol, from which it is freed by distilling it with three or four times its volume of water.

Properties and Tests.—It is a colorless, thin, oily liquid, having a penetrating and oppressive odor and a burning, acid taste. It congeals at $-25^{\circ} C.$ ($-13^{\circ} F.$), crystallizing in laminae, and has no effect on polarized light when pure. It boils at $132^{\circ} C.$ ($269.6^{\circ} F.$), and evaporates without leaving any residue. Its specific gravity is 0.818. It is very sparingly soluble in water, to which it imparts its odor and taste. It unites in all proportions with alcohol, ether, glacial acetic acid, benzol, petroleum benzin, fixed and volatile oils. It dissolves iodine freely, a little phosphorus, camphor, many resins, and most alkaloids, yielding the latter again, on agitation, to water acidulated with sulphuric acid. In contact with sulphuric acid it acquires a deep-red color, and reacts violently with concentrated nitric acid. Exposed to air in contact with platinum-black, it is slowly oxidized, yielding valerianic acid. It takes fire with difficulty unless heated to about $55^{\circ} C.$ ($131^{\circ} F.$), when it burns with a bright flame. As met with in commerce, it contains variable quantities, sometimes 12 per cent., of *active amyl alcohol*, which has the same elementary composition, but turns polarized light to the left and boils at $127^{\circ} C.$ ($260.6^{\circ} F.$); its amyl sulphate of barium is much more soluble in water than the corresponding salt obtained from inactive amyl alcohol. In addition to this, five other amyl alcohols have been prepared artificially, varying in their boiling-points between 97° and $137^{\circ} C.$ (206.6° and $278.6^{\circ} F.$).

The *purity* of amyl alcohol is ascertained by its specific gravity, its boiling-point, its volatility without residue, and by its not diminishing in volume when agitated with an equal bulk of solution of calcium or sodium chloride.

Composition.—Amyl alcohol is *amyl hydrate*, $C_5H_{11}HO$, and yields a series of compounds homologous with those of ethyl alcohol—namely, amyl ether, $(C_5H_{11})_2O$, amyl aldehyd or valer-aldehyd, $C_5H_{10}O$, and valerianic acid, $C_5H_{10}O_2$.

Pharmaceutical Uses.—Amyl alcohol is the source of valerianic acid and of various compound ethers (fruit-essences), and may be used as a solvent in the manufacture of alkaloids and other proximate principles.

Physiological Action and Medical Uses.—The adulteration of alcoholic drinks with *fusel oil* has been supposed to explain the rapid and peculiar intoxication they sometimes produce and the dyspeptic and nervous disorders which follow their habitual use. It is certain that the oil itself will cause, even in small doses, tension and pain in the head, and in large doses insensibility or a profound and death-like sleep. In small doses, on the other hand, it acts as a direct nervous stimulant, and has been employed for the purpose of controlling the nervous weakness and irri-

tability to which confirmed drunkards are subject. We have known it to be habitually prescribed by skillful physicians for the relief, apparently, of some of the symptoms of chronic *phthisis*, but without apparent benefit.

ALCOHOL METHYLICUM.—METHYL ALCOHOL.

Spiritus pyroxylicus rectificatus.—*Pyroligneous (Pyroxylic) spirit or alcohol*; *Wood-naphtha*, E.; *Alcool méthylique, Alcool formique, Alcool de bois, Esprit de bois, Esprit pyro-ligneux*, Fr.; *Holzgeist, Methylalcohol*, G.

Formula CH_3HO . Molecular weight 32.

Preparation.—Methyl alcohol was first noticed by Boyle (1661); its difference from ordinary alcohol was observed by P. Taylor (1812), but it was not correctly characterized until investigated by Dumas and Peligot (1834). It is contained to the amount of about 1 per cent. in the aqueous portion of the distillate resulting from the destructive distillation of wood, together with acetic acid, acetone, aldehyd, allyl alcohol, empyreumatic oils, and other compounds; on the addition of chalk, acetate of calcium is produced, and the portion distilling below the boiling-point of water furnishes the crude methyl alcohol. To obtain it pure, fused calcium chloride is dissolved in it to saturation, whereby a crystallizable compound, $\text{CaCl}_2 \cdot 4(\text{H}_2\text{O})$, is formed, which is not decomposed by the heat of a water-bath, but acetone, lignone, and other impurities are found in the distillate. The residue is afterward diluted with water and heated, when dilute methyl alcohol passes over, which is left in contact with burnt lime and then rectified.

Properties.—Pure wood-spirit is colorless, limpid, of a peculiar odor, resembling alcohol and acetic ether, and of a warm taste. Its density is .814 at 0°C . (32°F .), and .798 at 20°C . (68°F .); it boils at about 65°C . (149°F .); burns with a pale-blue, scarcely luminous flame; is soluble in all proportions in water, alcohol, and ether; dissolves volatile oils, fats, many resins, and particularly chloride of calcium, whereby, as well as by its boiling-point, it is readily distinguished from *acetone*. Crystallized sulphate of copper is insoluble in absolute methyl alcohol, but the anhydrous salt yields a blue-green solution, from which, on the addition of a small quantity of water, the crystalline salt is precipitated (Klepl, 1882). The derivatives corresponding with those mentioned under ETHYL ALCOHOL are methyl ether, $(\text{CH}_3)_2\text{O}$ (see page 131), methaldehyd or formaldehyd, CH_2O , and formic acid, CH_2O_2 (see page 54). It is easily oxidized by solution of permanganate of potassium in the cold, while the color of the latter is more slowly altered by ethyl alcohol. For determining the presence of one or both of these alcohols Riche and Bardy (1875) proposed a process depending upon the differently-colored solutions obtained by the limited oxidation of ethyl and methyl aniline. Berthelot (1876) proposed to mix the alcohol with twice its bulk of concentrated sulphuric acid, when methyl alcohol will yield methyle ether, and ethyl alcohol ethylene gas, which is almost insoluble in water and sulphuric acid, but is readily absorbed by bromine.

Physiological Action and Medical Uses.—The vapors of methyl alcohol, diffused in the air, give rise to headache, dizziness, nausea, and loss of appetite. It was at one time employed as a stimulant in *pulmonary consumption, chronic catarrh, dyspepsia*, and *verminous affections*, but is now entirely disused. It was given in doses of from 10 to 20 drops several times a day.

ALDEHYD.—ALDEHYD.

Acetic aldehyd, Acetaldehyd, E.; *Aldehyde acétique (vinique)*, Fr.; *Aldehyd*, G.

Formula $\text{C}_2\text{H}_4\text{O}$ or CH_3CHO . Molecular weight 44.

Origin.—Aldehyd was noticed, but not isolated, by Scheele (1774), who supposed it to be ether. Doebereiner (1832) obtained its crystalline compound with ether, and Liebig (1835) isolated it and determined its relation to alcohol. Aldehyd is formed by the oxidation of alcohol and many of its derivatives; it is found among the products of the dry distillation of wood and sugar and on distilling various protein and other compounds with binoxide of manganese and sulphuric acid.

Preparation.—The processes mostly employed are—one devised by Liebig, the other a modification of that originally suggested by W. and R. Rogers. The former distils at a gentle heat a mixture of 2 parts each of alcohol and water and 3 parts each of sulphuric acid and binoxide of manganese. According to the latter, 3 parts of potassium bichromate in coarse powder and 12 parts of water are introduced into a glass retort, and a mixture of 4 parts of sulphuric acid and 3 parts of alcohol is slowly added, avoiding

rise of temperature, after which a moderate heat is applied. In both cases the distillate consists chiefly of aldehyd, ether, and alcohol; it is rectified at a temperature not exceeding 50° C. (122° F.), and the vapors conducted into ether, which is afterward charged with gaseous ammonia, when *aldehyd-ammonia*, $C_2H_4O.NH_3$, crystallizes. The crystals are washed with ether, decomposed by dilute sulphuric acid, and the distillate rectified over chloride of calcium.

Properties.—It is a colorless, thin, neutral, and very inflammable liquid, having a peculiar ethereal rather suffocating odor, and the spec. grav. .805 at 0° C. (32° F.). It boils at about 21° C. (69.8° F.), dissolves in all proportions of water, alcohol, and ether, forms with ammonia a very soluble crystallizable compound, yields with alcoholic solution of potassa a yellow resin (*aldehyd resin*), and in contact with air is converted into acetic acid. Aldehyd separates from ammoniacal solution of nitrate of silver a metallic mirror; this reaction becomes more delicate in the presence of caustic soda, so that, according to Tollens (1882), a mirror will be obtained in 1 day with a solution of aldehyd 1 part in water 250,000 parts, and a slight turbidity, yet with a solution of one-fourth this strength.

On being treated at ordinary temperatures or in a freezing mixture with gaseous hydrochloric acid, or zinc chloride, or sulphuric acid, anhydrous aldehyd is converted into two polymeric crystalline modifications, of which *paraldehyd* melts at 10.5° C. (50.9° F.) and boils at 124° C. (255° F.), while *metaldehyd* sublimes partly unaltered, without fusing, at 115° C. (239° F.). When distilled in contact with various chemicals, ordinary aldehyd is again produced. Paraldehyd is $(C_2H_4O)_3$, and dissolves in 60 parts of cold water, but requires a larger quantity of warm water for solution.

Physiological Action.—According to Lussana and Albertoni, aldehyd possesses more powerfully anti-putrescent properties than alcohol, a watery solution containing only 3 per cent. of it preventing the putrefaction of meat and of urine. From 45 to 75 grains dissolved in water and injected into the veins of a moderate-sized dog almost instantaneously arrest respiration and induce coma. In smaller doses it intoxicates and anæsthetizes. Introduced into the stomach, it irritates that organ, and may even occasion gangrene. Being very volatile, it is readily inhaled, small quantities accelerating the respiration, but large ones arresting it, while the action of the heart continues almost at the normal rate. During the stage of asphyxia the temperature may fall even as much as 7° or 9° F. Animals forcibly resist attempts to make them inhale the vapors of aldehyd, but in about a minute sensibility and motility are abolished. If the inhalation is prolonged the pupils dilate, respiration ceases, and the only sign of remaining life is the continued pulsation of the heart. Recovery takes place rapidly without vomiting or other unpleasant symptoms. Of thirty deeply-narcotized dogs, only two died. The brain is rendered anæmic during the inhalation, as happens also in anæsthesia by chloroform and ether. Aldehyd has been tried on man, but its property of arresting respiration and its irritant action upon the lungs and stomach are likely to prevent its further employment as an anæsthetic.

PARALDEHYD has been vaunted as a hypnotic and anodyne by Cervello and Morselli (*Centrabl. f. Ther.*, i. 198; *Med. News*, xlii. 244), and in this country by Dana (*Med. Record*, xxiv. 221). In the dose of 45 grains it is said to calm restlessness and insomnia, and procure unbroken sleep of from 4 to 7 hours' duration, and to leave behind neither languor, nausea, nor digestive disorder. It also acts as a diuretic. It has been found efficient in the *insomnia* of various acute diseases, and also in acute *mania* and the excited paroxysms of chronic insanity and dementia, but less so in cases of melancholy and hallucination and in epileptic or alcoholic *insanity*. In neuralgia it affords transient relief. It is proposed as substituting the good without the evil qualities of chloral. An objection to its use lies in its intense and unpleasant smell.

ALETRIS.—COLIC-ROOT.

Starwort, Star-grass, Blazing star, E.; *Alétris farineux*, Fr.; *Mehlige Aletris*, G.

The rhizome of *Aletris farinosa*, Linné.

Nat. Ord.—Hæmodoracæ.

Origin.—The plant grows in grassy places and sandy woods in the United States, and flowers in July and August. It has a circular cluster of lanceolate, sessile, radical leaves, which are about 5 inches (125 Mm.) long and spread star-like upon the ground, and from the centre of them rises the nearly naked scape, about 2 feet (60 Cm.) high, and bearing a spiked raceme of whitish flowers having a mealy appearance.

Description.—The rhizome is horizontal, about 1 or 1½ inches (25–38 Mm.) long, ¼ inch (3 Mm.) thick at the lower end, and about ⅜ inch (1 Cm.) at the upper end, flat-tish or concave on the upper surface, and densely tufted with the fibrous or scaly remnants of the leaves; on the lower surface convex and beset with numerous simple rootlets 2 or 3 inches (50–75 Mm.) long, the older ones being wiry and glossy-blackish or brown, the recent ones softer and whitish. The rhizome consists of four to six rather indistinct joints, is brown-gray externally, white internally, breaks with a mealy fracture, with protruding scattered wood-bundles, is inodorous, and has an amylaceous afterward persistently bitter taste.

Constituents.—The rhizome appears to be free from tannin, and to contain starch and a bitter principle which is more freely soluble in alcohol than in water.

Adulterations.—We have occasionally seen it adulterated with upright and horizontal rhizomes of other monocotyledonous plants, from which, however, it is easily distinguished.

Medical Action and Uses.—This humble plant, if we may credit the published accounts of its virtues, is at once tonic, emetic, purgative, diuretic, carminative, sialagogue, and anti-rheumatic, besides being “the most powerful of uterine stimulants.” It is probably little more than a simple bitter, and as such produces various effects according to its dose and mode of administration—in substance, in warm or cold infusion, in tincture, etc. The infusion is made with 1 ounce (Gm. 32) to a pint of water, and may be given in doses of a tablespoonful. The average dose of the powder is about 10 grains (Gm. 0.60).

ALISMA.—WATER PLANTAIN.

Plantain d'eau, Pain de grenouilles, Fr.; Froschlöffel, Wasservegerich, G.

Alisma Plantago, Linné.

Nat. Ord.—Alismaceæ.

Origin.—The plant is indigenous to Europe and North America, grows in swampy places and on the edges of ponds and rivers, and flowers from July to September. The American plant is regarded as a variety, *Alisma americanum, Gray.*

Description.—The rhizome consists of two or three united fleshy tuberous pieces, which vary in shape from oblong to subglobular, are externally of a blackish color and beset with numerous radicles, internally white and with scattered wood-bundles, and in the fresh state of a disagreeable sharp odor and taste. The leaves are on long petioles, ovate oblong or lanceolate, acute, frequently with a heart-shaped base, five- to nine-nerved, light-green, and of an acrid taste. The scape is about 2 feet (60 Cm.) high, three-edged, and bears a loose panicle of whitish perfect flowers, having six stamens and numerous pistils upon a flattish receptacle. The rhizome and leaves have been used medicinally.

Constituents.—Water plantain contains a butyraceous pungent volatile oil, of which Zuehl (1818) obtained .6 per cent. Neljubin found in it also an acrid resin.

Medical Action and Uses.—A singular commentary on the virtues of this plant may be found in the statement that it was once regarded as an infallible cure for hydrophobia. Whatever powers it possesses are probably due to an acrid principle which exists in the fresh leaves and is strong enough to irritate the skin. It has been supposed to be useful in *calculous* renal affections, in *dysentery, diarrhoea, chorea, and epilepsy*, and as an application to recent *bruises, swellings, and sores*. The powder of the leaves may be prescribed in doses of about 60 grains (Gm. 4); the powder of the root has been used in half that quantity; and a decoction of the leaves is made with “a handful” in a pint of water, and may be given in doses of 2 ounces.

ALKANNA.—ALKANET-ROOT.

Radix alkanæ, P. G.—Orcanetté, Fr.; Alkannawurzel, G.

The root of Alkanna (*Anchusa, Linné*) tinctoria, *Tausch.*

Nat. Ord.—Boraginaceæ.

Origin.—This perennial herb is a native of Western Asia and South-eastern Europe, is about a foot (30 Cm.) high, and has nearly sessile flowers with a whitish corolla-tube, purplish throat, and blue margin. It is cultivated in Southern Europe.

Description.—The root is a foot (30 Cm.) or less in length, of the thickness of a finger, several-headed, and often crowned with the remnants of white hairy leaves. The soft loose bark separates in thin layers, has a dark-purple color, like the medullary rays, and

covers a harder, yellowish, irregularly twisted and spongy wood. Alkanet-root is nearly inodorous and almost tasteless.

Constituents.—The principal constituent of the bark is the red coloring matter, which has been called *anchusin*, *alkannin*, and *anchusic acid*. To obtain it the root, previously exhausted with cold water, is treated with alcohol, the tincture slightly acidulated with hydrochloric acid, concentrated, and agitated with water and ether. On evaporation of the latter the acid remains behind as a dark red-brown, brittle, resinous mass, which when carefully heated is sublimable in light floccules. It is readily soluble in alcohol, ether, fats, and most volatile oils, insoluble in water, and dissolves in alkalies with a blue color. On evaporating the tincture without previously acidulating it, or in the presence of ammonia, the acid gradually changes to *alkanet-green*, which dissolves in ether with a green color.

Uses.—Alkanet-root is mainly employed for coloring oils and pomades. The Oriental dye-stuff *alheenna*, corrupted into *alkanna*, is obtained from *Lawsonia alba*, *Lamarck*, s. *L. inermis*, *Linne*; in Oriental countries an infusion of the elliptic or broadly lanceolate entire leaves is used for dyeing the finger- and toe-nails orange-red.

Allied Plants.—The root of *Onosma echioides*, *Linne*, has a deep-red bark, and is sometimes used in Southern Europe in place of alkanet, but is inferior to it. The root and herb of the *ox-tongue* or *bugloss*, *Anchusa officinalis*, *Linne*, were formerly used in medicine; they have an insipid, mucilaginous taste. The root resembles alkanet in shape, but is externally blackish-brown, internally white.

Medical Uses.—Bugloss is said to have the same medicinal properties as borage (*Borago officinalis*), which are simply those of an emollient which becomes diaphoretic or diuretic according to the temperature and the quantity of the infusion in which it is administered. It is not used in this country. Alkanet-root has no medicinal virtues; its coloring matter is harmless.

ALKEKENGİ.—WINTER CHERRY.

Alkekenge, *Coqueret*, Fr.; *Judenkirsche*, *Schlutte*, G.

The fruit of *Physalis Alkekengi*, *Linne*.

Nat. Ord.—*Solanaceæ*.

Origin.—It is a perennial herb, indigenous to Middle and Southern Europe, and to some extent cultivated and naturalized in this country under the name of *strawberry tomato*. It is more or less soft-hairy, has a nearly simple stem, broadly ovate and pointed leaves with a somewhat wedge-shaped base, and bell-shaped greenish-white unspotted flowers.

Description.—The fruit is spherical, of the size of a cherry, scarlet-red, shining, and remains enclosed in the inflated orange-colored permanent calyx. It is two-celled, and contains numerous white flattish ovate seeds attached to a central placenta. In the fresh state the fruit is very juicy and has a sweet and acidulous taste; it shrivels considerably on drying.

Constituents.—Dessaignes and Chautard (1852) found sugar and citric acid in the berries, and in the leaves and calyx an amorphous bitter principle, *physalin*, $C_{14}H_{16}O_5$, which is obtained as a whitish powder on agitating the cold aqueous infusion with chloroform, and is soluble in chloroform and alcohol, but sparingly so in ether, cold water, and diluted acids.

Allied Species.—*Physalis viscosa*, *Linne*, a clammy, pubescent North American plant, with ovate or oblong, slightly cordate and somewhat toothed leaves, and purplish-brown flowers. The fruit is an orange-colored or reddish berry, remaining in the inflated calyx.

Phys. pennsylvanica, *Linne*. It resembles the preceding, but is not clammy, the leaves are usually entire, the corolla is veined in the centre, and the berry has a red color.

Phys. peruviana, *Linne*, *Ph. pubescens*, *Linne*, and *Nicandra physaloides*, *Gartner*, are indigenous to South America and employed for similar purposes. The last-named species is occasionally found wild in the United States, where it is known as *apple of Peru*.

Physiological Action and Medical Uses.—The herb is used in Europe as tonic, anti-periodic, and depurative, and the fruit as febrifuge and diuretic. Like many other bitter plants, this one is sometimes successful in arresting the paroxysms of *intermittent fever*, and is used for that purpose by the peasantry. The berries eaten when ripe and fresh, and when dried and used to prepare a decoction, and also their expressed juice, are regarded as having decided diuretic virtues, and are frequently employed in

jaundice, gravel, dysury, retention of urine, and dropsy. It is recommended to give the fresh berries to the extent of several ounces a day; of the expressed juice 2 or 3 fluid-ounces; and an infusion of the dried berries, made with an ounce (℥m. 32) in a pint of hot water, to the extent of 2 or more pints a day. The powder of the plant is used in doses of a drachm or more (℥m. 4). The allied species appear to resemble winter cherry in their qualities.

ALLIUM, U. S.—GARLIC.

Bulbus allii.—*Ail.* Fr.; *Knoblauch*, G.

The bulb of Allium (*Porrum*, *Reichenbach*) sativum, *Linné*. Bentley and Trimen. *Med. Plants*, 280.

Nat. Ord.—Liliaceæ.

Origin.—All the plants belonging to this genus are bulbous, resemble each other in their odor and taste, and contain similar if not identical volatile oils. The officinal species is indigenous to Central Asia, and perhaps also to the basin of the Mediterranean, but is cultivated for culinary purposes in other sections of Europe and North America. By cultivation and hybridization several varieties have been formed, one of which, of frequent occurrence here, was proved by R. P. Thomas (1860) to be a hybrid of *A. sativum* and *A. Porrum*, *Linné*, which is distinguished by its larger bulb, higher stem, and the absence of proliferous bulbs from the flowering heads.

Description.—Garlic is a sub-globular compound bulb, surrounded by a few dry membranaceous scales, which cover the remnant of the upright stem and the 5 to 8 small bulbs or cloves arranged in a circle around its base. These bulblets are oblong in outline, compressed from both sides, wedge-shaped toward the stem, and rounded upon the back. They consist of a few thick fleshy scales and a short fleshy axis. Garlic has a peculiar pungent and disagreeable odor and an acrid, burning taste. It is used in the fresh state only.

Constituents.—Besides the cellular tissue, garlic contains between 50 and 60 per cent. of water, 35 per cent. of mucilage, some albumen, sugar, starch, and about $\frac{1}{4}$ per cent. of volatile oil, to which its odor and taste are due. In its crude state *oil of garlic* is of a dark brown-yellow color, heavier than water, of a very repulsive taste, and consists of oxide and sulphides of allyl. The rectified oil consists mainly of the sulphide, $(C_3H_5)_2S$, is colorless, lighter than water, and may be obtained artificially by treating an alcoholic solution of potassium sulphide with allyl iodide. It dissolves easily in alcohol and ether, and sparingly in water; with nitrate of silver, mercuric chloride, and other metallic salts it forms crystalline compounds. Garlic, macerated in water or vinegar, yields its virtues to these liquids.

Preservation.—Garlic is best preserved in a dry place at a moderate temperature, in which it slowly parts with its water. A. P. Sharp proposed (1864) to put the fresh and cleaned bulblets into a jar and add a small quantity of alcohol—about 2 ounces to a quart jar. The vitality of the bulbs is destroyed, and they retain their properties in the closed vessel for a long period, but change in color, acquiring a brownish somewhat diaphanous appearance.

Off. Prep.—*Syrupus allii*, U. S.

Allied Species.—The following species of Allium are more or less cultivated for culinary purposes: their bulbs and leaves possess a garlic-like but mostly milder odor, which is dependent upon similar volatile oils. Medicinally, they appear to have the same properties, though in a milder degree:

Allium Cepa, *Linné*; Onion, *E.*; Oignon, *Fr.*; Zwiebel, *G.*

Al. Porrum, *Linné*; Leek, *E.*; Porreau, *Fr.*; Lauch, *G.*

Al. Ascalonicum, *Linné*; Shallot, *E.*; Echallotte, *Fr.*; Schallotte, *G.*

Al. Schœnoprassum, *Linné*; Chives, *E.*; Civette, *Fr.*; Schnittlauch, *G.*

Physiological Action and Medical Uses.—Garlic, as well as leek and onion, is a stimulant to the part to which it is directly applied and to the whole system. Its odorous element may be perceived on the breath and its taste in the mouth when the bruised bulb has been applied to the skin. When eaten raw its odor exhales from many parts of the body, and, given to nursing women, it taints their *milk*, so that their infants refuse the breast. It reddens the skin, and may even vesicate it. Internally, it stimulates the digestive organs, and is everywhere used, but principally in southern countries, as a condiment for various kinds of food. Excessive quantities of it produce nausea, vomiting, colic, and diarrhœa. The odor of garlic is popularly employed to revive persons

from a *swoon* or from *hysterical* insensibility. It is a vermifuge not to be neglected in the treatment of *lumbricoid worms* when given by the mouth, and for destroying *ascarides* when administered by the rectum. Many cases of *dropsy*, particularly of *anasarca* produced by cold, have been cured by a diet of bread and raw onions. This regimen will sometimes produce copious diuresis. Onions boiled in milk have been used successfully for a like purpose. Bruised cloves of garlic and poultices of boiled onion are admirable remedies for chronic *bronchitis* in children. They should be applied over the whole front of the chest. Internally, garlic is a very useful agent in the same affection. It is also a domestic remedy for *whooping cough*. Onion poultices are particularly applicable to *abscesses*; the core of a roasted onion relieves *earache* when introduced into the auditory canal. Onion and garlic cataplasms applied to the perineum relieve *strangury*. The dose of bruised or chopped garlic or of the expressed juice is about 30 grains (Gm. 2).

ALNUS.—ALDER-BARK.

Black Alder, E.; *Écorce d'aune*, *Aune noir*, Fr.; *Erlenrinde*, *Schwarzerle*, *Eller*, G.

The bark of *Alnus glutinosa*, Gærtner, s. *Betula Alnus*, *Linné*, and of *Alnus serrulata*, Aiton.

Nat. Ord.—Betulaceæ.

Origin.—The first species is a tree about 30 feet (9 M.) high, indigenous to Europe and Northern Asia; the second is a native of the United States, and attains a height of about 10 feet (3 M.). Both grow in moist localities.

Description.—The bark is in quills or curved pieces about $\frac{3}{16}$ inch (1.2 Mm.) thick, smooth on both sides, of a brownish ash-gray color externally, the young bark with reddish-brown dots, brownish-orange on the inner surface, inodorous, and of an astringent somewhat bitter taste. It is brittle, and breaks with an uneven, not splintery, fracture. The bark of the American species, which is called *black alder*, resembles the preceding, but is of a blackish-gray externally; has small suberous warts, which become somewhat confluent transversely, and is marked with a few coarse longitudinal striæ upon the orange-brown inner surface.

Constituents.—Alder-bark contains tannin, that of the black alder about 4 per cent. and the aments of the same species 1.5 per cent. (Bowman, 1869). These results were obtained by precipitation with gelatin. According to Stenhouse (1843), the tannin of the European alder-bark is precipitated by gelatin, but not by tartar emetic; ferric acetate yields a purplish-blue, and ferrous chloride a dark olive-green, precipitate.

Medical Action and Uses.—The American species of alder is said to be "astringent and diuretic," which may be doubted, since astringents are seldom diuretics. Its astringency resides in the leaves, as well as in the bark, with both of which a decoction is prepared for the treatment of *diarrhœa* and *hæmaturia*; and the former, when bruised, are applied to *contusions*, *sprains*, and *ulcers*. The inner bark is said to be emetic. The European species possesses almost identical virtues. Its decoction is employed for the purposes above mentioned, and as a gargle in *sore throat*, as a mouth-wash in *ulceration* of the gums, etc., as an injection in *leucorrhœa*, etc.; and the bruised leaves are sometimes applied to the mammae to lessen the secretion of *milk* or dissipate *indurations* during lactation. Internally, the bark has been used in *intermittent fever*. The dose of the powdered bark is 10 grains (Gm. 0.60) several times a day. The decoction or infusion may be made with half an ounce (Gm. 16) to a pint of water.

ALOE, U. S., Br., P. G.—ALOE.

Aloès, Fr.; *Aloe*, G.

The inspissated juice of the leaves of different species of Aloe. Bentley and Trimen, *Med. Plants*, 282, 283, 284.

Nat. Ord.—Liliaceæ.

Officinal Varieties.—1. ALOE BARBADENSIS, Br., U. S. 1870.—Barbadoes aloès, Hepatic aloes, E.; Aloès hépatique des Barbades, Fr.; Barbadoes Aloe, G.—From *Aloe vulgaris*, *Lamarck*.

2. ALOE CAPENSIS, U. S. 1870; Aloe, P. G., Aloe lucida.—Cape aloes, E.; Aloès du Cap, Aloès lucide, Fr.; Capaloe, G.—From *Aloe ferox*, *Lamarck*, *A. spicata*, *Thunberg*, A. Lingua, *Linné*, s. *Gasteria Lingua*, *Willdenow*, and of other species of Aloe.

3. ALOE SOCOTRINA, Br., U. S. 1870, Aloe, U. S. 1880, Aloe succotrina.—Socotrine aloes, E.; Aloès sucotrin, A. socotrin, Fr.; Socotora Aloe, Socotrinische Aloe, G.

Origin.—In aspect these plants resemble the so-called century-plant, or American aloe, *Agave americana*, *Linneé*. Of the above-named species, *Aloe vulgaris* has yellow flowers, and is indigenous to India and North-eastern Africa, and has been naturalized along the shores

FIG. 11.

*Aloe vulgaris*, *Lamarck*.

of the Mediterranean and in the West Indian Islands; *A. indica*, *Royle*, *A. littoralis*, *Koenig*, and several other forms described as distinct species, are now regarded as mere varieties of this. *A. socotrina*, with orange-red flowers, belongs to the east coast of Africa, near the southern shore of the Red Sea, and to the neighboring islands of the Indian Ocean. *A. purpurascens*, *Haworth*, *A. rubescens*, *De Candolle*, and *A. officinalis*, *Forskal*, which are indigenous to tropical or Southern Africa, have been referred to this species as varieties. *A. spicata*, with yellowish and orange-colored flowers, and *A. ferox*, with reddish or yellowish flowers, are indigenous to the southern part of Africa, together with *A. africana*, *Miller*, *A. linguiformis*, *Linneé*, *A. arborescens*, *Miller*, and other species, which are used in preparing some of the commercial aloes. The aloes-plant of the island of Socotra, according to Balfour (1882), is *Aloe Perryi*, *Baker*, a species quite distinct from *A. soco-*

trina; it is used for preparing aloes which, however, does not appear to reach our commerce. *Aloe abyssinica*, *Lamarck*, is probably the source of Jafferabad aloes, met with in commerce in Bombay.

Preparation.—The large fleshy leaves of these plants contain in their central part an insipid, thick, mucilaginous juice, and a bitter yellowish juice in distinct, elongated, thin-walled ducts situated near the surface. To obtain this bitter juice the leaves are cut off near their base, and then placed in suitable vessels, into which their cut ends project. The vessel used in Barbadoes and other West Indian islands is an inclined trough from which the juice flows into other vessels, where it is preserved until it can be evaporated. In the Cape Colony a shallow ditch is dug into the ground and covered with a goat-skin, which, when nearly filled, is emptied at once into an iron kettle, and without much attention boiled down to the proper consistence. Greater care is bestowed upon the evaporation of the juice in Barbadoes and Curaçao, the impurities being removed during the evaporation, and when of sufficient consistence the juice is poured into boxes or gourds, where it solidifies on cooling. Socotrine aloes seems to be mostly derived from Zanzibar and other places farther north on the east coast of Africa. It enters commerce by way of Bombay. Nothing is known of the method pursued in its manufacture, except that the juice appears to be inspissated by spontaneous evaporation. The importation of all kinds of aloes into the United States varies between 96,500 pounds in 1876 and 230,624 pounds in 1882.

ALOE PURIFICATA. *U. S.*—Purified aloes. *E.*; Aloës dépuré, *Fr.*; Gereinigte Aloe, *G.*

Aloes 100 parts (17 ounces av.); Alcohol 15 parts (3 fluidounces). Heat the aloes, by means of a water-bath, until it is completely melted. Then add the alcohol, and, having stirred the mixture thoroughly, strain it through a fine sieve which has just been dipped into boiling water. Evaporate the strained mixture by means of a water-bath, constantly stirring, until a thread of the liquid becomes brittle on cooling. Lastly, break the product, when cold, into pieces of convenient size, and keep it in well-stopped bottles.—*U. S.*

The process remains the same as heretofore; its object is the removal of fragments of leaves, wood, stones, pieces of skin, and other extraneous matter, which are always found in larger or smaller proportion in Socotrine as well as in Cape aloes. If the heat is regulated by means of a water-bath, there is no danger of impairing the virtues of aloes by

overheating. The melted aloes is rendered sufficiently fluid, by the addition of the alcohol, to pass without difficulty through the sieve, if this has been previously warmed. The impurities remain upon the sieve, and the strained liquid may be at once evaporated. If the operation has been carefully performed, purified aloes will be dull-brown or reddish-brown, brittle, of the peculiar aromatic odor of Socotrine aloes, and will yield a bright brownish-yellow powder.

Description.—1. **BARBADOES ALOES.** It is usually imported in gourds, and has a deep-brown or orange-brown color, which in thin pieces has a decidedly yellow or reddish-yellow tinge; it is opaque in mass, translucent in thin splinters, and breaks with a smooth scarcely conchoidal, waxy fracture. When breathed upon it has a strong saffron-like odor, which is, however, distinct from that of Socotrine aloes. Ether dissolves about 10 per cent. of Barbadoes aloes.

Similar in appearance, but rather darker and more glossy, are *Curacao* and *Bonaire aloes*; their fracture is more conchoidal and their odor less agreeable.

2. **CAPE ALOES.** This is readily distinguished from the other kinds by its dark, blackish-brown color (which is frequently of an olive tint), its glossy appearance, and its large conchoidal fracture. It is transparent on the edge, with a red-brown color, and has a saffron-like but disagreeable sourish odor. It affords a light yellowish-brown or greenish-brown powder, and yields to ether from 1.5 to 6.5 per cent. of soluble matter. It is imported in cases, and varies more or less in the shade of color and in the brilliancy of its fracture.

3. **SOCOTRINE or ZANZIBAR ALOES.** This is put up in skins, and of late years also in kegs and tin-lined boxes. It is sometimes met with in the liquid state, and separates then into two distinct layers, of which the upper one is transparent, while the lower consists of a brown-yellow crystalline mass. Even when quite hard externally the interior of the packages is often found in a soft or semi-fluid state. When carefully dried it has a conchoidal, dull fracture, and is of a yellowish orange-brown color, destitute of the greenish hue of Cape aloes. On exposure the color darkens considerably upon the surface. The powder is of a bright brownish-yellow. When breathed upon it emits an aromatic saffron-like odor, more pleasant than that of the other varieties. From 4 to 5.5 per cent. of Socotrine aloes is soluble in ether.

4. **OTHER VARIETIES OF ALOES.** Under the name of *hepatic aloes* a variety of Socotrine aloes was formerly known in Europe, which came into commerce from the East Indies. The name was afterward applied to any opaque liver-colored variety. In the United States this name has been used to designate Barbadoes aloes. *Natal aloes* is an opaque variety of a brownish-gray or light brownish-yellow color, differing very considerably in appearance from the preceding varieties. It is prepared from an undetermined species in the interior of Natal, the juice being concentrated by careful boiling. *Jafferabad aloes* is of a black pitch-like color and lustre, a glassy somewhat porous fracture, and, in powder, of a pale-brown hue; its odor and taste are less agreeable than those of Socotrine aloes. An inferior kind, known in European commerce as *Moka aloes*, comes from the interior of Arabia; it is opaque, almost black, of irregular fracture and disagreeable odor, and yields a pale reddish-brown powder. By the name of *Caballine* or *horse aloes* European writers used to designate the inferior, impure, and fetid kinds of different origin.

The difference in the sensible properties of the different varieties of aloes must in part be referred to the species from which they are derived, and to the climate and soil in which the plants grow; and it must depend to a considerable extent upon the care bestowed upon obtaining the bitter juice free from the insipid mucilaginous contents of the cells of the interior parenchyma, upon the manner in which concentration is effected, and upon its freedom from accidental impurities. These latter are perhaps never absent, but are sometimes present in considerable proportion, although not readily observable on the examination of the aloes; hence the U. S. Pharmacopœia orders the purification of Socotrine aloes. The opaqueness of some sorts of aloes is due to the crystallization of one of the principles. The glossy and transparent kinds do not contain such a crystallized principle, but are nearly homogeneous. The odor of aloes is best observed when a sample is breathed upon; it resembles strongly saffron, associated with another odor, which is distinct for each kind. The taste of aloes is disagreeably bitter and very persistent.

Aloes dissolves almost completely in alcohol and in boiling water, the latter solution separating, on cooling, about 40 to 60 per cent. of the so-called *resin of aloes*, which is taken up by alkalis and reprecipitated by acids. Chloroform in contact with aloes remains uncolored even when heated to boiling; pure ether acquires only a slight yellowish color.

Constituents.—None of the older analyses have thrown any light upon the compo-

sition of aloes beyond establishing the degree of solubility of different samples in several solvents and the behavior of these solutions with different reagents. T. and H. Smith of Edinburgh succeeded (1851) in isolating from Barbadoes aloes a crystalline principle, which was then named *aloin*, but is now called *barbaloin*, to distinguish it from the crystalline principles of other varieties. Socotrine aloes, containing a large number of crystals, was noticed by Pereira in 1852, and the crystalline principle was isolated by Groves (1856), but then regarded as being identical with barbaloin, until their difference was shown by Histed (1871). Groves's process consists in dissolving 1 part of aloes in 10 parts of boiling water, decanting after cooling from the sediment, and acidulating slightly with hydrochloric acid. Tilden (1870) prefers acidulating the water with sulphuric, sulphurous, or hydrochloric acid before dissolving the aloes, and allowing to rest overnight; the clear liquid is then rapidly evaporated to about 2 parts, and set aside in a cool place to crystallize; the crystals are purified by recrystallization from very dilute alcohol. Nataloin was obtained by Flückiger (1871) by triturating Natal aloes with an equal weight of alcohol at a temperature not exceeding 48° C. (118° F.), when the amorphous portion will be dissolved; the residuary crystalline mass, after washing with cold alcohol, is recrystallized from hot methylic or ethylic alcohol. Socaloin, being soluble in cold spirit almost as freely as the amorphous constituents, cannot be obtained in the same manner; but Histed succeeded in preparing it with little loss by mixing powdered Socotrine aloes with a little alcohol (sp. gr. .960), expressing strongly between calico, and crystallizing the press-cake from warm weak alcohol. The same process yields also the aloin of Jafferabad aloes (Shenstone, 1882).

Barbaloin, $C_{17}H_{20}O_7$, occurs in small yellow prismatic needles, which are insoluble in ether, and dissolve sparingly in cold but freely in warm water and alcohol. Bromine-water produces in its solution a yellow precipitate of *bromaloin*, which crystallizes in needles. Heated with nitric acid, barbaloin yields chrysammic, aloetic, picric, and oxalic acids. Barbaloin, added to a drop of nitric acid, produces a crimson color, which rapidly fades. According to Hanausek (1881), the aloin from Curaçao aloes has the same behavior to reagents, but its composition is $C_{15}H_{17}O_7$.

Nataloin, $C_{16}H_{18}O_7$, crystallizes best from methylic alcohol in thin pale-yellow rectangular scales, which dissolve at 15.5° C. (60° F.) in 35 parts of methylic alcohol, 50 of acetic ether, 230 of absolute alcohol, and 1236 of ether. It is sparingly soluble in hot and cold water and in about 60 parts of alcohol. Nitric acid does not convert it into chrysammic acid, but yields oxalic and picric acids. Nataloin, added to a drop of nitric acid, produces a crimson color, which is more permanent than the similar color produced with barbaloin. If nataloin is added to a drop of sulphuric acid and the vapor of fuming nitric acid is passed over the surface, the orange-colored liquid will assume a fine green color, quickly changing to red and blue (Histed, *Transac. Br. Pharm. Conf.* 1871, p. 580).

Socaloin or *Zunaloin*, $C_{15}H_{16}O_7$, crystallizes in small yellow needles, which dissolve in 30 parts of alcohol, 90 of water, 380 of ether, 9 of acetic ether, and freely in methylic alcohol. Cold nitric acid has little effect upon socaloin, but upon heating imparts to it an orange-red color, and oxidizes it to the same acids which are obtained with barbaloin. Precisely the same effect was observed by Shenstone with the aloin from Jafferabad aloes; hence these three aloins form a well-defined group quite distinct from nataloin.

Aloetic acid, $C_7H_2(NO_2)_2O$, is an orange-red powder. *Chrysammic acid*, $C_{14}H_4(NO_2)_7(OH)_2O$, forms bright golden-yellow laminae, yields crystallizable salts having a metallic lustre, and by nascent hydrogen and other deoxidizing agents is converted into *hydrochrysamide*, which is sublimable, and crystallizes in indigo-colored needles.

The above formulas for the three aloins are those of Sommaruga and Egger (1874), and if correct would prove these principles to be homologous. Stenhouse's formula for crystallized barbaloin is $(C_{34}H_{36}O_{14} \cdot H_2O)$; Tilden's formula for nataloin = $C_{25}H_{28}O_{11}$; Flückiger's formula for socaloin = $C_{34}H_{38}O_{15} + 5H_2O$. Tilden (1875) considers barbaloin and socaloin, although differing in chemical and some physical properties, to have the composition $C_{16}H_{18}O_7$, but to unite with different proportions of water of crystallization. These results were confirmed by E. Schmidt (1876). On pouring a solution of aloin into an excess of bromine-water, a precipitate of *bromaloin*, $C_{16}H_{15}Br_3O_7$, is obtained, which crystallizes from alcohol in beautiful yellow needles. Nataloin does not yield a similar bromine compound.

Kosmann did not succeed (1863) in obtaining a crystallizable body from Cape aloes; he assigned to the yellow amorphous portion, soluble in water and alcohol, the formula $C_{34}H_{22}O_{20}$, and stated that the insoluble portion had nearly the same composition, and that both were glucosides.

Tilden and Rammell examined (1872) the so-called resin from Barbadoes and Socotrine aloes, and observed that by continued boiling a portion of it can be rendered permanently soluble in water. This and the insoluble portion are nearly alike in composition, and appear to differ from barbaloin merely by the elements of water, and, for the insoluble resin also, by containing less hydrogen. This view is somewhat supported by the change into an amorphous substance when aloin is boiled for a long time with water, or more rapidly in the presence of a little alkali, while small quantities of acid prevent this change. The amorphous *aloetin*, *aloesin*, and *aloebitter* of older investigators must have been aloin similarly modified.

By continued boiling of Socotrine aloes with alkali, Czumpelick (1861) obtained, among other compounds, crystals of an acid which Hlasiwetz (1865) procured by boiling aloes with dilute sulphuric acid, and named *paracumaric acid*; on fusing this with potassa, *para-oxybenzoic acid* is formed. The latter is also yielded by the same process from aloes, together with oxalic acid, volatile fatty acids, and orcin, and, according to Weselsky (1872), *aloeic acid*. The latter is soluble in alcohol and ether, sublimable, and acquires a transient purplish-violet color with chlorinated soda.

On distilling aloes with zinc-dust, Graebe and Liebermann (1868) obtained *anthracene*, $C_{14}H_{10}$, and E. Schmidt also *methylanthracene*. On distilling aloes with lime, Robiquet (1846) separated a colorless or yellowish oil, *aloisol*, of an odor resembling that of amyl alcohol and oil of bitter almond. Rembold (1866) ascertained this aloisol to be a variable mixture of acetone, xylene, and other compounds. When incinerated, aloes yields from 1 to 4 per cent. of ash.

Pharmaceutical Uses.—For internal use *purified* aloes only should be dispensed. The following preparations have been admitted into the pharmacopœias: Aloë purificata, *U. S.*; Enema aloes, *Br.*; Extract. aloes aquosum (Barbadosis and Socotrinæ), Extr. colocynthidis comp., *U. S.*, *Br.*; Pilulæ aloes. Pil. aloes et asafœtidæ, Pil. aloes et ferri, *U. S.*, *Br.*; Pil. aloes et mastiches, *U. S.*; Pil. aloes et myrrhæ, *U. S.*, *Br.*; Pil. cambogiæ comp., Pil. colocynthidis comp., Pil. colocynthidis et hyoseyami, *Br.*; Pil. rhei comp., Tinct. aloes, *U. S.*, *Br.*; Tinct. aloes et myrrhæ, *U. S.*; Tinct. benzoini comp., Vinum aloes, *U. S.*, *Br.*

PULVIS ALOES ET CANELLÆ. *Hiera Pica.*—Rub together and mix thoroughly Socotrine Aloes 4 ounces, Canella 1 ounce.—*U. S.* 1870.

Physiological Action.—Aloes acts upon quadrupeds as a purgative. Given to dogs in the dose of 60 grains, it caused the liver to secrete a greater quantity of biliary matter in a given time, although it rendered the bile more watery. It was long ago known to have a purgative effect when applied in solution to the unbroken skin, and more recently when endermically used. Hypodermic injections of a solution of aloin have caused purgation. Infants are purged by the milk of nurses using aloes. In doses of 1 or 2 grains it stimulates the appetite and improves the digestion; in doses of from 3 to 6 grains it occasions, after a delay of from 12 to 24 hours, a fecal and usually formed stool; in larger doses it excites more or less tormina, and tenesmus attends the evacuations. They have a peculiar smell, which has been ascribed to bile. At the same time slight feverishness is apt to occur, and, according to some, a sense of tension in the liver. According to Rutherford, it powerfully stimulates the liver, increasing the secretion of biliary matter, but rendering the bile more watery. It is doubtless this fact, connected with the slight purgative action of the drug, that has in all ages caused it to be used in the dyspeptic derangements named below. Habitual use of aloes does not sensibly diminish its activity. It is presumed to act decidedly upon the lower bowels, since it causes an increase of the hemorrhoidal flux when it exists, and tends to bring on or augment the menstrual flow. Genital irritation is sometimes manifested. The general belief that aloes tends to produce hemorrhoids is contradicted by the results of experience: these bodies probably arise from the constipation which aloes is given to relieve. The evident stimulation of the pelvic organs by aloes has led to its use as an abortifacient, but there is no case on record which conclusively proves it to be so. It is held by some that *aloin* is two or three times as active as good aloes. Its cathartic action is said to be uniform, rather more speedy than that of crude aloes, and unattended by griping. 14 grains will, it is said, in a strong adult usually cause two or three copious evacuations; 2½ grains have been followed by powerful catharsis, producing five or six evacuations (Harley). But, on the other hand, D. Beaumetz hesitates to ascribe any purgative action to aloin, and holds it to be very slight when it exists at all.

Medical Uses.—The salutary action of aloes upon the stomach and liver, and its slow and moderate operation as a purgative, have led to its use in habitual *constipation*:

and it enters into numberless compounds devised for the relief of this condition, especially as it presents itself in persons of sedentary habits, on the approach of old age, as an effect of repeated pregnancy, etc. It is said to be contraindicated by a plethoric, bilious, or hæmorrhagic constitution, when the liver is congested, during pregnancy, and when hæmorrhoids exist; but these statements are not justified by experience. As regards hæmorrhoids, those attended with a mucous discharge are most apt to be benefited by aloes. *Ascarides* of the rectum may often be destroyed by enemas of aloes, of which the best consists of aloes dissolved in an infusion of quassia. *Jaundice* from "hepatic torpor" or congestion may be successfully treated with purgative doses of aloes combined with blue pill. The condition so called, however, usually depends on constipation. In simple *amenorrhœa* of the torpid sort aloetic purgatives are very efficient, especially in the form of tincture, or of the pill of aloes and myrrh, or of the powder of aloes and canella. Aloes and iron are equally valuable in cases of *menorrhagia* arising from debility, and enemas of aloes and soap have been found serviceable in curing atonic *uterine catarrh*. Aloetic laxatives will sometimes arrest *gleet*. Powdered aloes, which is used in veterinary surgery, has been found of great service in treating lacerated wounds (Millett). The other local applications of aloes are described in connection with the tinctures into which that substance enters.

Administration.—Aloes in pilular form is best administered alone, or simply associated with soap or with an alkaline carbonate to promote its solution. As a laxative it may be given in the dose of from 3 to 10 grains (Gm. 0.20–0.60). Custom has, however, sanctioned its use in combination with mastic for this purpose. The tincture and the wine of aloes are occasionally used as purgatives. Its combinations with myrrh, with asafetida, and with canella are especially adapted to the treatment of derangements of the catamenia, and those with benzoin are used as internal and also as local stimulants. Aloin may be substituted for aloes in the various pills containing the latter. As a prescription for the relief of habitual constipation due to sluggishness of the bowels or torpor of the liver the following formula has been recommended: $\mathcal{R}$. Aloes gr. $\frac{1}{2}$; Ferri sulph. exsic. gr. iss; Quinæ sulph. gr. j; Capsici gr. $\frac{1}{2}$; Ext. nucis vomic. gr. ss; Ext. gentianæ q. s. ut fñ. pil. To be taken two or three times a day, after meals.

ALSTONIA.—DITA-BARK.

Écorce de dita, Fr.; *Ditarinde*, G.

The bark of *Alstonia* (*Echites*, *Linné*) *scholaris*, R. Brown. Bentley and Trimen, *Med. Plants*, 173.

Nat. Ord.—Apocynaceæ.

Origin.—Dita-bark comes from a stately forest tree indigenous to the East Indies, Eastern Australia, the Philippines, and other neighboring islands. The wood is soft and white, and the greenish-white flowers have, in the night, a strongly aromatic odor.

Description.—The bark is in thick curved pieces, usually about 2 or 4 inches (5 to 10 Cm.) long, $\frac{1}{2}$ an inch (12 Mm.) broad, and $\frac{1}{4}$ to $\frac{1}{2}$ inch (3 to 8 Mm.) thick. It is externally of a leather color, has a scaly appearance from its longitudinal and transverse fissures, and is not unfrequently marked with small black spots. Internally it is light yellowish-brown, the inner surface brown-gray and longitudinally striate. The bark breaks with a short, or rather horny, somewhat porous fracture, showing in the outer layer groups of yellow stone-cells, and in the inner layer narrow wavy medullary rays, and yields a yellowish-gray powder, which is inodorous and has a slightly bitter not unpleasant taste.

Constituents.—G. Gruppe of Manilla obtained from dita-bark about 2 to 5 per cent. of *ditaine*, which was uncrystallizable, very hygroscopic, and bitter. Jobst and Hesse (1875) obtained from the aqueous solution of the alcoholic extract by acetate of lead a precipitate containing a crystalline and an oily acid, by subacetate of lead a precipitate containing resin-like bodies, and by phosphotungstic acid a precipitate containing the alkaloid *ditamine*, $C_{16}H_{19}NO_2$, which is a white bitter powder soluble in ether, alcohol, chloroform, and benzol, and by sulphuric acid is colored red, on warming violet-red; by nitric acid yellow, on warming dark-green to violet. Only .02 per cent. of the alkaloid was obtained, which yields very bitter salts. The bark yields to petroleum benzin several fatty and resinous substances, named *echicouatchin*, *echiretin*, *echicerin*, *echitin*, and *echitein*, and the three last of which are crystallizable. Harnack (1877) isolated a crystalline alkaloid, *ditaine*, which Hesse (1881) named *echitamine*, $C_{22}H_{28}N_2O_4$. It forms glossy prisms containing $4H_2O$, is a strong base, is almost insoluble in benzol and benzin, and dissolves readily in water, alcohol, and, if freshly pre-

precipitated, also in ether and chloroform. Its hydrochlorate is sparingly soluble in cold water and nearly insoluble in hydrochloric acid and in alkali chlorides. Sulphuric acid imparts a deep purplish-red color, changing to green. Hesse obtained also a third alkaloid, *echitamine*, $C_{20}H_{27}NO_4$, which is amorphous, brown, easily soluble in alcohol, less so in water, and is colored reddish-violet by sulphuric acid, and purple, afterward green and yellow, by nitric acid.

The closely-allied *poelë-bark* of Java, which comes from *Alstonia spectabilis*, *R. Brown*, yielded to Hesse 0.8 per cent. of echitamine, or fully six times the quantity contained in dita-bark; it contains also the other alkaloids in larger proportion than the latter; and in addition thereto *alstonamine*, which resembles ditamine in behavior, but is crystallizable; it was isolated by A. Scharlée in 1862, and then named *alstonine*, but this name is now used for one of the alkaloids of Australian *alstonia*-bark.

Allied Drug.—*ALSTONIA-BARK*, from *Alstonia constricta*, *F. Mueller*, a native of Australia, differs greatly in appearance from dita-bark in being $1\frac{1}{2}$ to 2 inches (3 to 5 Cm.) thick, deeply furrowed, externally brown-gray, or after abrasion ochrey-yellow, and ridged upon the inner surface: the bast-layer is about $\frac{1}{4}$ inch (6 Mm.) broad, yellow, tough and fibrous, and is covered by the thick, spongy, and friable corky layer, which is composed of alternating bands of lighter and darker ochre color, these bands being present also in the much thinner bark from young wood, with a relatively thin periderm; the powder is grayish-yellow, odor slight, taste persistently bitter.

The bark was described and its origin determined by Charles Mohr (1879). Palm (1863) found in it a neutral bitter principle, *alstonin*: Hesse (1865) two alkaloids, *chlorogenine* and *porphyrrine*: Mueller and Rummel described an alkaloid, *alstonine*; and Oberlin and Schlagdenhauffen (1879) a second uncrystallizable alkaloid, *alstonicine*. The alkaloids characterized by Hesse in 1881 are: *alstonine* (chlorogenine), $C_{21}H_{29}N_2O_4$, a brownish-yellow amorphous powder, readily soluble in alcohol, and, when freshly precipitated, also in chloroform and water, sparingly soluble in ether; its salts are insoluble in dilute acids: *porphyrrine*, $C_{21}H_{23}N_3O_3$, a white amorphous powder, soluble in petroleum naphtha, freely soluble in ether, alcohol, and chloroform, the acid solutions of a blue fluorescence: sulphuric or nitric acid dissolves it with a purple color, that with nitric acid changing to yellowish- and brownish-green; *alstonidine* crystallizes from its solutions in chloroform, ether, alcohol, acetone, and hot petroleum naphtha; is not colored by sulphuric or nitric acid, but its solutions show blue fluorescence. One or more other alkaloids are present in minute quantity.

Alstonia-bark gives 9 to 10 per cent. of ash, and on successive treatment yields to ether about 1, to alcohol 28, and to water 1.4 per cent. of soluble matter.

Allied Species.—In the East Indies the root of *Echites malabarica*, *Lamarck*, is used as a febrifuge, and the leaves as an application to carbuncles; the leaves of *Ech. caryophyllata*, *Roxburgh*, in arthritic fevers; and the bark of *Ech. pubescens*, *Buchanan*, and *Ech. antidysenterica*, *Roxburgh*, like the Brazilian *Ech. Cururu*, *Martius*, *Ech. insignis*, *Sprengel*, and *Ech. longiflora*, *Desfontaines*, in diarrhoea and dysentery. *Ech. syphilitica*, *Linné filius*, of Surinam, is used there in syphilitic complaints.

Under the name of *conessi-bark* the bark of one or two of the above species has sometimes been used; but true *conessi-bark* is referred to *Wrightia* (*Holarrhena*) *antidysenterica*, *R. Brown*. It contains an alkaloid which was discovered by Haines (1858), but obtained pure by Stenhouse (1864), and has been named *conessine*, *wrightine*, and *kurchicine*; it is white, amorphous, bitter, and readily soluble in alcohol, ether, and dilute acids.

Medical Uses.—Dita-bark and also its alkaloid are said to have been used successfully in *intermittent fever* in the East Indies, where also curare is employed for the same purpose. Harnack's ditaine closely resembles curare in its physiological action, but is said to act much less energetically. According to Cathcart, "the bitter bark of *Alstonia constricta*, sometimes called native quinine, is in common use by the shepherds in the interior of Southern Australia as a domestic remedy for malarial fevers" (*Am. Jour. Pharm.*, Aug. 1879, p. 405).

ALTHÆA, U. S.—MARSHMALLOW-ROOT.

Radix althææ, P. G.—*Racine de guimauve*, Fr.; *Altheewurzel*, *Eibischwurzel*, G.

The root of *Althæa officinalis*, *Linné*. Woodville, *Med. Bot.*, 198; Bentley and Trimen, *Med. Plants*, 35.

Nat. Ord.—Malvaceæ.

Origin.—This perennial herb is indigenous to the temperate portion of Northern and Western Asia and to the greater part of Europe, and has been naturalized in the salt-marshes along the coast of New England and New York. For medicinal purposes the root of the cultivated plant is generally employed; and in Europe the leaves, and occasionally the flowers, are likewise used.

Description.—The root is fit for use when 2 or 3 years old; of older roots only the fleshy branches are used, the woody main root being rejected. It is collected early in the spring or in autumn, and deprived of its brown-yellow cork and outer bark by peeling. It forms nearly cylindrical somewhat tapering, pieces about 3 to 8 inches (7 to 20 Cm.) long, and about $\frac{1}{2}$ an inch (12 Mm.) in diameter. It is of a white color externally and internally, breaks with a short and granular fracture, which is fibrous only in the cortical portion from the long slender bast-fibres, visible also upon the surface of the commercial article and imparting to it a somewhat hairy appearance. The surface shows longitudinal folds, and is marked with the brownish circular scars of the radicles. The transverse section is of a yellowish-white color, exhibits the internal bark, in diameter about one-tenth of the root, and separated by the brown cambium-line from the medullium, in which ligneous bundles are not discernible with the naked eye. The medullary rays are quite narrow; the bast-fibres are united to small groups, and these arranged somewhat in concentric circles; the wood-bundles consist of a few wood-cells and 3 or 4 ducts marked with circular or elongated dots; the thin-walled parenchyma contains starch with scattered cells containing crystalline clusters of calcium oxalate, and larger cells filled with mucilage. Marshmallow-root has a faint, peculiar aromatic odor and a sweetish mucilaginous taste.

Young and peeled *belladonna*-roots bear some resemblance to marshmallow, but are readily distinguished by the absence of the hair-like bast-fibres upon the surface and by the yellowish wood-bundles which are plainly visible.

The leaves (*Folia althææ*, P. G.) are petiolate, 2 or 3 inches (5 to 8 Cm.) long, roundish-ovate or subcordate, irregularly crenately toothed, and often three- or five-lobed, of a grayish-green color, and both sides velvety-downy with stellate hairs; their taste is mucilaginous.

The medium-sized *flowers* have a nine-leaved downy involucre, 5 sepals and petals, the latter rose-colored and retuse above; stamens numerous, united in a column and with the short claws of the petals; taste mucilaginous.

Constituents.—A. Buchner obtained (1832) from marshmallow-root 37.5 per cent. starch, 35.6 mucilage, 11 pectin, 8 asparagin and sugar, 1.25 fixed oil, 1.8 glutinous matter, 7 cellulose, and 8 phosphate of calcium. Cold water will take up the mucilage, sugar, and asparagin, and by the decoction will, in addition thereto, contain starch.

Asparagin, $C_4H_8N_2O_3 \cdot H_2O$, was discovered (1805) by Vauquelin and Robiquet in asparagus, and by Bacon (1826) in marshmallow-root. L. A. Buchner obtained it (1862) in a convenient manner by dialyzing the mucilaginous infusion in water and concentrating this solution to the crystallizing point. It forms colorless, inodorous, and nearly tasteless crystals, which are insoluble in strong alcohol and ether. It unites with both acids and alkalies, and when boiled with them is converted into *aspartic* or *amido-succinic acid*, $C_4H_7NO_4$, and ammonia; hence asparagin is *amido-succinamide*. Nitrous acid converts it into malic acid, $C_4H_6O_4$, water, and nitrogen.

Allied Species.—Nearly all the plants of the natural order Malvaceæ possess mucilaginous properties, and many are employed in their native countries in regular or domestic practice. The following appear to deserve a passing notice:

ALTHÆA TAURINENSIS, De Candolle, of Southern Europe, has a rather woody root, which is used like marshmallow-root.

ALTHÆA (ALCEA, *Linné*) ROSEA, Cavanilles, Hollyhock, *E.*: Rose-trémière, Passe-rose, *Fr.*: Stock-rose, Stockmalve, *G.*, is indigenous to the Levant, frequently cultivated in gardens. The flowers, *Flores malvæ arboreæ*, are nearly sessile, 3 or 4 inches (7 to 10 Cm.) in diameter, have a tomentose calyx, a six-cleft involucre, and 5 broad or retuse petals, which are connected at the base with the column of the united stamens. The purple-colored flowers are generally preferred.

MALVA SYLVESTRIS, *Linné*, High mallow, *E.*: Mauve sauvage, Grande mauve, *Fr.*: Käsepappel, Waldmalve, *G.* It is a native of Europe, somewhat naturalized in North America, has an erect or decumbent stem, about 2½ feet (.75 M.) high, roundish-reniform and sharply five- or seven-lobed and crenately-toothed leaves, and purplish, dark-veined flowers, which resemble the preceding, but are only 1 inch (25 Mm.) wide, and have a pubescent three-leaved involucre. The dried flowers, *Flores malvæ (vulgaris)*, P. G., are bluish, and turn green with ammonia and red with acids.

MALVA VULGARIS, *Fries*, s. *M. neglecta*, *Wallroth*, resembles the preceding, but the stem is procumbent, the leaves are smaller and obtusely lobed, and the petals rose-colored or whitish. The leaves of this and the preceding species constitute the *Folia (herba) malvæ*, P. G.: *Mallow-leaves*, *E.*; *Feuilles de mauve*, *Fr.*; *Malvenblätter*, *G.*

MALVA ROTUNDFOLIA, *Linné*, Common mallow, *E.*: Petite mauve, *Fr.*: Käsekraut, *G.*, is indigenous to Europe, extensively naturalized in America; has a procumbent stem, round heart-shaped somewhat lobed and crenate leaves, whitish flowers with slightly retuse rather short petals, and numerous wrinkled one-seeded carpels circularly arranged.

HIBISCUS (ABELMOSCHUS, Guillemin et Perrottet) ESCULENTUS, *Linné*, Okra or Gombo. Bentley and Trimen, *Med. Plants*, 36. It is indigenous to tropical Africa, and cultivated in most tropical and subtropical countries. The heart-shaped about five-lobed toothed leaves and the unripe capsules are used. The latter are about $2\frac{1}{2}$ and sometimes 10 inches (6–25 Cm.) long, pentagonal, narrow cylindrical, tapering above, hairy, often curved, and contain many roundish reniform seeds.

ABELMOSCHUS MOSCHATUS, Moench, s. Hibiscus Abelmoschus, Linné, indigenous to India and Egypt, naturalized in tropical America, yields *Semen abelmoschi, s. Grana moschata*—Musk-seed. E.: *Ambrette, Graine de musc*, Fr.; *Moschukoerner, Bisamkoerner*, G. These seeds are flattish reniform, about $\frac{1}{8}$ inch (3 Mm.) long, grayish-brown, concentrically striate, blackish at the hilum, internally whitish and oily, and have a thin endosperm and curved embryo. The strong musk-like odor resides in the testa, and becomes more apparent on rubbing or warming. The seeds are used in perfumery as a substitute for musk.

ABUTILON AVICENNE, Gartner, s. Sida Abutilon, Linné, indigenous to India and China, naturalized in Europe and America, is known here as *velvet leaf*, and has roundish heart-shaped, pointed, irregularly toothed, pale-green, velvety leaves and yellow flowers.

Pharmaceutical Uses.—Powdered marshmallow-root, being very absorbent, is advantageously used to impart to soft pill-masses the proper consistence.

Off. Prep.—**SYRUPUS ALTHÆÆ, U. S.**

SPECIES EMOLLIENTES, P. G. A mixture of equal parts of bruised marshmallow-leaves, mallow-leaves, melilot, German chamomile-flowers, and flaxseed.

SPECIES AD GARGARISMA, P. G. 1872. A mixture of equal parts of cut marshmallow-leaves, mallow-flowers, and elder-flowers.

SPECIES PECTORALES, P. G. Pectoral tea, E.; *Espèces pectorales, Fr.*; Brustthee, G. A mixture of thinly-cut marshmallow-root 8 parts, peeled liquorice-root 3 parts, orris-root 1 part, colt's-foot leaves 4 parts, mullein-flowers and anise each 2 parts.—*P. G.* Equal parts of the flowers of mallow, marshmallow, mouse-ear, colt's-foot, red poppy, violet, and mullein.—*P. P.* Although composed of seven flowers, it is known in France as *quatre-fleurs*.

SPECIES PECTORALES CUM FRUCTIBUS, P. G. 1872. A mixture of pectoral tea 16 parts, cut St. John's bread 6 parts, pearl barley 4 parts, and cut figs 3 parts.

Medical Action and Uses.—Marshmallow is an emollient protective, and is somewhat nutritious. It is employed in Europe as a *demulcent* in all inflammatory and irritable conditions of the mucous membrane of the respiratory, digestive, and urinary organs, and poultices formed of the bruised or powdered root are applied to local *inflammations of the skin*. The decoction has been used as an injection to allay irritation of the *vagina* and of the *rectum*. It is prepared by adding the sliced root to hot water, to the production of a mucilage of the required thickness. The root is made use of in France, as orris-root is elsewhere, for teething children to bite upon. The so-called marshmallow paste contains no marshmallow. All the other plants above enumerated may be used, like marshmallow, as demulcents.

ALUMEN, U. S., P. G.—ALUM.

Aluminiæ et Potassii Sulphas, U. S. 1870; Sulphas aluminico-potassicus.—*Potassa Alum, Sulphate of aluminium and potassium, E.; Alum, Sulfate d'alumine et de potasse, Fr.; Alaun, Kalialaun, G.*

Formula $K_2Al_2(SO_4)_4 \cdot 24H_2O$. Molecular weight 948.

Alumen, Br.; Aluminiæ et ammoniæ sulphas, Sulphas aluminico-ammonicus.—*Alum, Ammonia alum, E.; Alun ammoniacal, Fr.; Ammoniakalaun, G.*

Formula $(NH_4)_2Al_2(SO_4)_4 \cdot 24H_2O$. Molecular weight 906.

Origin.—Alums are compound sulphates, readily crystallizing in cubes and octahedrons of the regular system, and containing 24 molecules of water of crystallization, and 2 atoms each of a univalent and trivalent basylous radical. The most important trivalent radicals which are capable of forming alums are aluminium, chromium, and iron, and the univalent radicals potassium, sodium, and ammonium. Ordinarily, the name *alum* is indiscriminately used for the aluminio-ammonium and for the aluminio-potassium alum, the former being recognized as such by the British Pharmacopœia, while the United States, French, and German Pharmacopœias recognize the latter only.

Salts possessing a styptic taste (among them alum) were known and employed in ancient times. In the Lipari Islands it appears to have been found as the product of disintegration of alum-stone and alun-slate, and in the sixth century B. C. it was employed by the Phœnicians in dyeing. But the ancient Greek name, *stypteria*, and the Latin, *alumen*, were

given alike to various minerals and different products, and afterward the latter were insufficiently distinguished for many centuries. The earthy constituent of alum was by Marggraf (1754) first shown to be distinct from lime. Agricola and Libavius in the sixteenth century had recognized the necessity of using putrid urine (ammonia compounds) for the production of alum. Marggraf had observed that alumina and sulphuric acid would not produce alum until after the addition of potash; but the existence of alkali in alum was first proven by Lavoisier (1777), and by Chaptal and Vauquelin (1797), the latter showing that either potash or ammonia may be present. Soda alum was first prepared by Macintosh at the beginning of the present century. The exact composition of alum was further determined by Vauquelin, Thénard, Berzelius, and others.

The minerals most largely used in the manufacture of alum are *alum-stone*, or *alumite*, and *alum-slate*. The former contains aluminium and potassium sulphates and aluminium hydrate; the latter consists mainly (about two-thirds) of clay or aluminium silicate, the remainder being pyrites (sulphide of iron) and bituminous matter, together with small quantities of lime, manganese, etc.

Preparation.—When calcined clay containing but little iron (pipe-clay) is treated with sulphuric acid until a pasty mass is obtained, this, on exposure to the air, will be gradually converted into sulphate of aluminium, which needs merely to be mixed, while in solution, with ammonium or potassium sulphate to obtain crystals of alum. Previous to calcination the clay is often mixed with 12 to 15 per cent. of charcoal or coke, after which the combination with the sulphuric acid is more readily effected. This is one of the processes employed in the United States, where alum is also made from cryolite by heating it with strong sulphuric acid, washing with a little cold water, dissolving the aluminium sulphate in hot water, and adding potassium or ammonium sulphate.

To prepare alum from alum-stone, this is calcined and then made into heaps, which are kept moist; after several months it has become disintegrated and converted into alum, which is extracted by water and crystallized.

Alum-slate or shale is broken up and made into heaps, which are exposed to the air for several months or years; or, if the mineral be very hard, it is first subjected to a process of slow roasting by stratifying it with wood or coal, setting fire to the heaps, and covering it more or less in order to prevent too great a rise of temperature. During the exposure the sulphur of the pyrites is oxidized to sulphuric acid, aluminium and iron sulphates being formed, which are obtained in solution by lixiviating the heaps with water. This solution is concentrated, and while hot mixed with potassium chloride, which, reacting with the ferric sulphate, yields potassium sulphate and ferric chloride, the latter remaining in solution in the mother-liquor, from which the alum separates on cooling as a crystalline powder. If the lixivium of the alum-heaps does not contain sufficient ferric sulphate, the chloride of potassium is partly replaced by the sulphate. It is obvious that by this process potassa alum is obtained, or ammonia alum if the corresponding ammonium compound is substituted for the potassium salt. The alum is purified by one or two recrystallizations, the last one being performed in large vats which can be taken apart.

The potassium chloride necessary in this process is obtained as soap-boiler's waste and as the refuse of saltpetre-refineries. The ammonium sulphate is cheaply obtained from the liquor of gas-works.

Alum is extensively manufactured in the United States, but its consumption in the arts is so great that over 8,500,000 pounds of the different commercial kinds were imported in 1878, the importation having been reduced since 1880 to less than 2,500,000 pounds.

Properties.—The two official alums are similar in every respect, except that the ammonia alum gives the odor of ammonia on the addition of an excess of hydrate or carbonate of potassium, and, when heated to full redness, leaves finally alumina. Potassa alum, at a white heat, leaves a mixture of alumina and sulphate of potassium; but if mixed with one-third its weight of sugar or similar organic matter, the mixture carbonized and afterward heated to redness in a flask, contact with air being avoided, a powder known as *Homborg's pyrophorus* is obtained, which consists of an intimate mixture of alumina, charcoal, and potassium sulphide, and which ignites spontaneously on exposure to the air.

Alum crystallizes in colorless, inodorous, transparent regular octahedrons, which are usually combined with the cube. Its specific gravity is 1.724—of ammonia alum, only 1.631. It has an acidulous sweetish and astringent taste, and a strongly acid reaction to test-paper. Its aqueous solution dissolves iron, zinc, and other metals which are soluble in diluted sulphuric acid, with the evolution of hydrogen. It is insoluble in alcohol or ether, effloresces slightly on exposure to the air, losing at 40° C. (104° F.) 2.7 per cent.,

and at 47° C. (116.6° F.) 9.6 per cent. of water; when heated to about 92° C. (197.6° F.) it fuses in its water of crystallization (45.57 per cent.), and after this has evaporated at a higher heat solidifies again. (See ALUMEN EXSICCATUM.) Ammonia alum loses all its water of crystallization (47.6 per cent.) at above 205° C. (401° F.), but potassa alum persistently retains a little water when heated to 280° C. (536° F.). At a full red heat both are decomposed, but to effect the complete decomposition of potassa alum a white heat is required, when sulphuric and sulphurous anhydride and oxygen are given off. According to Poggiale (1843), 100 parts of water dissolve at—

	0°	10°	20°	30°	40°	50°	80°	100° C.	
Ammonia alum,	5.22	9.16	13.66	19.29	27.27	36.51	103.08	421.9	parts.
Potassa alum,	3.9	9.52	15.13	22.01	30.92	44.11	134.47	357.48	“

The determinations made by Mulder (1864) closely agree with those of Poggiale for ammonia alum, but differ considerably for potassa alum. 1 part of the latter, according to Redtenbacher (1865), dissolves at 17° C. (62.6° F.) in 7.41 parts, and according to Poggiale, at 20° C. (68° F.) in 6.61 parts, and at 10° C. (50° F.) in 10.5 parts of water; this last figure is given by both the United States and German Pharmacopœias as the solubility of alum at 15° C. (59° F.), while Mulder's results at the same temperature are 10.9 parts.

Tests.—The alkalies and alkaline carbonates precipitate white gelatinous hydrate of aluminium, which is insoluble in ammonia and the carbonated alkalies, but dissolves in an excess of caustic soda and potassa. Commercial alum always contains a little iron, from which it cannot be completely freed by recrystallization. It is owing to its presence that solutions of alum become blue on the addition of ferrocyanide of potassium, and yield a grayish precipitate with sulphhydrate of ammonium. The limit of this impurity is thus ascertained: “A solution of 1 Gm. of alum in 30 Ccm. of water should not assume more than a bluish coloration on the addition of a drop of test solution of ferrocyanide of potassium.”—U. S. The German Pharmacopœia, which requires alum to be free from iron, very properly directs the testing to be done at ordinary temperature, and limits the time for the non-appearance of a bluish color to 10 minutes; the reagent is gradually, and on heating rapidly, decomposed by alum solution, with the production of a green and blue color. The solution of alum in caustic potassa or soda should not give off the odor of ammonia (absence of more than traces of ammonia alum), nor should it yield a precipitate with sulphuretted hydrogen or sulphide of ammonium (absence of zinc and other metals).

Pharmaceutical Uses.—For the preparation of *Alumen exsiccatum*, *Aluminium hydraz*, and other aluminium compounds.

Physiological Action.—Primarily, alum constricts all organic fibres, and hence tends to diminish blood-supply and secretion in living parts; but, secondarily, it increases both as a result of its continued use. This operation it is of the utmost importance to remember in its therapeutical applications. It is said to exert a destructive action upon the enamel of the teeth. Alum is absorbed from the stomach, and is found in the urine, liver, and spleen (Orfila); but its local action is that of an irritant, whereby it readily excites vomiting when freely administered. Its operation is not violent, however, and it does not occasion nausea. In other words, it is a mechanical emetic.

Medical Uses.—Alum is of advantage in several *hæmorrhages*, and particularly in those of a passive type. Thus, in gastric and intestinal hæmorrhage its efficacy will depend upon whether the blood is rapidly or slowly extravasated; in pulmonary hæmorrhage, which is generally active, its efficiency is not very great; while in *menorrhagia* and *hæmaturia* it is appropriately and beneficially employed. In various *fluxes* its astringent operation is advantageous. In *gastric* and *intestinal catarrh* it represses the secretion of mucus, and the vomiting or diarrhœa that results therefrom. The *diarrhœa* of *typhoid fever* is better treated by alum than by any other astringent, except, perhaps, acetate of lead. In chronic *dysentery* it is a valuable remedy for occasional use, and even in the acute form of the disease alum enemata have been found efficient. In other *fluxes* it may lessen the discharge, as in *diabetes*, but its utility is not very great. In *diabetes insipidus* or *polyuria* it would probably be more useful. Formerly, it had much repute in chronic *bronchial fluxes*, and it is still found advantageous in diminishing excessive secretion from the air-passages, and not merely in chronic but also in acute bronchitis, and especially in that form which occurs as an element of *whooping cough* and is attended with a profuse expectoration of ropy mucus. Strangely enough from a rational point of view, some forms of *constipation* are favorably affected by alum, as that in which

the condition depends upon atony of the bowels maintained by habitual distension of them by flatus. It is still more singular that in *lead colic*, a disease in which the intestine is spasmodically contracted, alum has been proved efficient in overcoming the constipation. For this purpose it should be given in doses of from 1 to 3 drachms (Gm. 4–12) daily, dissolved in a large quantity of water slightly acidulated with sulphuric acid. As an emetic, alum may be employed whenever mechanical emetics are indicated, and particularly in *pseudo-membranous laryngitis*, or true *croup*, a disease in which such emetics are peculiarly indicated, but in which nauseants are exceedingly mischievous. In *narcotic poisoning* similar evacnants are indicated, and none is better than alum, especially in children. It probably operates not only as an emetic, but by its astringent action on the gastric mucous membrane it checks the absorption of the poison. Alum is one of the many remedies that occasionally cure *intermittent fever*, even after the failure of quinia. It is still used in India, where burnt alum is preferred, and given in doses of 8 grains (Gm. 0.50) 3 hours before the expected paroxysm.

The topical uses of alum are numerous. It is extensively employed to arrest *hemorrhage*. As a local hemostatic it is used to check bleeding from the nostrils, gums, anus, vagina, bladder, and rectum, from leech-bites and from the sockets of extracted teeth, etc. In all such cases it may be applied in powder, or in a strong solution upon sponge or lint. The solution should be used warm, and allowed to cool where it is applied. Lotions of alum-water are useful in repressing local and general *sweats*, and particularly the fetid secretions of the feet, armpits, etc.; the solution should not be strong, and should be applied warm: it is improved by the addition of salicylic acid. In *ophthalmia* a solution of 4 or 5 grains (Gm. 0.25) to the ounce of water may be instilled into the eye, but a much better method is to apply a poultice made by stirring finely-powdered alum and white of egg together, and enclosing the coagulated albumen in a cambric bag. This application is a most excellent one for recent *ecchymoses*. *Aphonia* from laryngeal atony is diminished by gargles of a drachm of alum in 2 or 3 ounces (Gm. 4 in Gm. 100) of barley-water; and the same remedy is of constant use for the relief of *sore throat*, especially of that form of *tonsillitis* in which the soft parts are tumid. In the graver forms of *angina*, and especially in *diphtheria* and *gangrenous pharyngitis*, gargles, insufflations, and atomized solutions of alum have been much employed; they probably tend to promote the separation of the exudation, if not to check its formation. As far as the local treatment of the diseases in question goes, alum is useful, although less so than other agents; but they, and especially diphtheria, are not local affections, and cannot be cured by such treatment merely. Alum washes are useful in all the forms of *stomatitis*, but especially in the ulcerative form. In subacute, in mild acute, and in chronic *laryngitis* gargles containing alum are of decided advantage, but the medicine is still more useful when it is applied to the interior of the larynx in an atomized solution. Finely-powdered alum or burnt alum is one of the best applications for *ingrown teeth*, as when a posterior molar tooth of the lower jaw becomes partially covered by the gum, subjecting it to contusion and irritation and producing a very painful sore. The overhanging flesh should be first cut away with a gum-lancet. In the analogous affection, *ingrown toe-nail*, the same application is of great use if ulceration with granulation has already taken place; but it is essential that scraped lint should be introduced between the nail and the sore, and that the movement of the parts should be restricted by a narrow roller of adhesive plaster. The stimulant and astringent action of alum makes it a useful application in *chilblains*. In all cases of morbid and exuberant action of mucous membranes, besides those above noticed, alum renders important services. For indolent *ulcers*, whether arising from *burns* or otherwise, and for all profuse mucous and purulent discharges from mucous membranes, when the inflammatory element is not active and the parts are relaxed, it is one of the best remedies. Its efficacy is shown conspicuously in cases of *relaxation* of the *gums*, *urula*, *pharynx*, *vagina*, and *anus*. In vaginal *leucorrhœa* alum injections are better than any others, and washes of the same in leucorrhœa of the vulva. In the former of these two affections a tampon of cotton coated with finely-powdered alum may be applied by means of a speculum, or a cylinder of cotton cloth saturated with a solution of alum, of which the strength should vary with the grade of inflammation present. Injections of a solution of alum may be used in the treatment of *gonorrhœa* and *gleet* in the male, a weak solution being generally the most efficient. Some physicians, however, give a preference to a saturated solution. A mixture of alum, mucilage, and sulphuric ether has been applied to carious cavities for the relief of *toothache*.

Administration.—Alum may be administered internally in doses of from 5 to 40 grains (Gm. 0.30–2.60), mixed with powdered sugar or with syrup. A few grains of

some aromatic prevent its nauseating effects. The emetic dose is from 1 to 2 drachms (Gm. 4–8), given in syrup; when retching commences vomiting may be promoted by warm water. *Alum whey* is made by boiling 2 drachms (Gm. 8) of powdered alum in a pint of milk, and straining; the *curd* left behind is applicable to the purposes already mentioned, and may be prepared with white of egg instead of milk. *Alum gargles* are made with from half an ounce to an ounce (Gm. 15–30) of alum in a pint of water, which may be sweetened with honey. For *collyria* a solution of 2 or 3 grains (Gm. 0.10–0.20) of alum in an ounce of water is usually sufficient; for *hæmostatic* uses a hot saturated solution is preferable.

“*Acetate of alumina*” has been proposed for antiseptic purposes as a substitute for carbolic acid (*Times and Gaz.*, May, 1880, p. 506).

ALUMEN EXSICCATUM, U. S., Br.—DRIED ALUM.

Alumen ustum, P. G.—*Burnt alum*, E.; *Alun calciné*, A. *desséché*, A. *brulé*, Fr.; *Gebannter Alumin*, G.

Formula $K_2Al_2(SO_4)_4$. Molecular weight 516.

Preparation.—Alum, in small pieces, 183 parts; to make 100 parts. Expose the alum for several days to a temperature of about 80° C. (176° F.), until it has thoroughly effloresced. Then place it in a porcelain capsule and gradually heat it to a temperature of 200° C. (392° F.), being careful not to allow the heat to rise above 205° C. (400° F.). Continue heating at the before-mentioned temperature until the mass shall have become white and porous, and weighs 100 parts. When cold, reduce it to a fine powder and preserve it in well-closed vessels.—U. S.

Take of Alum 4 ounces; heat it in a porcelain dish or other suitable vessel till it liquefies; then raise and continue the heat, not allowing it to exceed 408° F., till aqueous vapor ceases to be disengaged and the salt has lost 47 per cent. of its weight. Reduce the residue to powder, and preserve it in a well-stoppered bottle.—Br.

The first process is identical with that of the German Pharmacopœia, except that the latter permits the heating of alum only to 160° C. (320° F.); but since potassa alum is not decomposed short of a red heat, the limiting of the temperature, as directed, is not necessary: the final product of the U. S. Pharmacopœia retains about .5 per cent., that of the German Pharmacopœia (5.5 parts from 10 parts of alum) about 1.5 per cent., of water. Ammonia alum, which is recognized by the British Pharmacopœia, parts with 45 per cent. of water at 190° C. (374° F.), and with all its water at 205° C.: the dried alum retains about .6 per cent. of water.

Properties.—After exsiccation, dried alum forms a light porous mass which is easily rubbed into a white granular powder. It is very slowly (but completely) soluble in cold water, but dissolves in a short time in 1.5 times its weight of boiling water, these tests being sufficient to prove its faultless preparation. Owing to its slow solubility its taste is at first slight, but soon becomes more styptic than that of crystallized alum. *Impurities* may be detected in the same manner as in alum.

Medical Uses.—Dried alum is a powerful astringent and stimulant, and when applied to tissues in process of growth may become escharotic. Hence, as was more particularly pointed out in the preceding article, it is used to repress *fungous granulations* and stimulate indolent and sanious *ulcers*, as well as mucous membranes tending to hypertrophy, with morbid secretion. Powdered dried alum is peculiarly fitted for insufflation.

ALUMINII HYDRAS.—HYDRATE OF ALUMINIUM.

Alumina hydrata, P. G. 1872; *Argilla pura s. hydrata*.—*Aluminium hydroxide*. *Hydrated alumina*, E.; *Hydrate d'alumine*, Fr.; *Thonerdehydrat*, G.

Formula $Al_2(OH)_6$. Molecular weight 156.

Origin.—Aluminium hydrate is occasionally found native, forming the rare crystalline minerals *gibbsite*, $Al_2(OH)_6$, of North America, and *diaspore*, $Al_2(OH)_2O_2$, of Eastern Europe. For use in medicine it is prepared by precipitating the solution of an aluminium salt with an alkali or alkaline carbonate. Alumina is more frequently found in the ashes of cryptogamous plants than in those of phænogams.

Preparation.—Alum 11 parts; Carbonate of Sodium 10 parts; Distilled Water a sufficient quantity. Dissolve each salt in 150 parts of distilled water; filter the solutions and heat them to boiling. Then, having poured the hot solution of carbonate of sodium into a capacious vessel, gradually pour in the hot solution of alum with constant stirring,

and add about 100 parts of boiling distilled water. Let the precipitate subside, decant the clear liquid, and pour upon the precipitate 200 parts of hot distilled water. Again decant, transfer the precipitate to a strainer, and wash it with hot distilled water until the washings give but a faint cloudiness with test solution of chloride of barium. Then allow it to drain, dry it at a temperature not exceeding 40° C. (104° F.), and reduce it to a uniform powder.—*U. S.*

On mixing solutions of sodium carbonate and alum a decomposition takes place, resulting in the formation of sodium sulphate and potassium sulphate, which remain in solution; aluminium hydrate, which is precipitated; and carbonic acid gas, which escapes; $3\text{Na}_2\text{CO}_3 + \text{Al}_2\text{K}_2(\text{SO}_4)_4 + 3\text{H}_2\text{O}$ yield $3\text{Na}_2\text{SO}_4 + \text{K}_2\text{SO}_4 + \text{Al}_2(\text{HO})_6 + 3\text{CO}_2$. If ammonia alum be used, ammonium sulphate remains in solution in place of potassium sulphate; the sodium carbonate may be replaced by an equivalent quantity of potassium or ammonium carbonate. On adding the alkaline carbonate to the alum solution the precipitated aluminium hydrate persistently retains sulphuric acid and alkali; but on slowly adding the alum solution to the alkaline carbonate, so that the latter remains continually in excess, only a minute amount of basic sulphate will enter into the precipitate, and will be almost completely decomposed by digesting the latter with the alkaline liquid. In order to obtain it absolutely free from sulphate, Berzelius found it necessary to redissolve the washed aluminium hydrate in hydrochloric acid, and to precipitate this solution with an excess of ammonia. The quantity of sodium carbonate ordered by the pharmacopœia is less than .5 per cent. in excess of the theoretical quantity of the pure salt, and, in the presence of a small amount of impurity, may prove inadequate for the complete decomposition of the alum; it is therefore advisable to use a partly effloresced carbonate, so that the mixed liquids after digestion may have a distinct alkaline reaction. For the decomposition of ammonia alum an equal weight of crystallized sodium carbonate is required. For the washing of the precipitate hot (not boiling) water is directed—a precaution necessary to avoid decomposition of the hydrate. Sainte-Gille (1855) determined that by prolonged contact with boiling water the hydrate, $\text{Al}_2(\text{HO})_6$, is formed, which is insoluble in dilute acids. Drying the aluminium hydrate at a low temperature leaves it in a smooth condition and prevents it from getting gritty. Most of the details of the above process were elaborated by Prof. Lloyd (1879). The yield is 1.8 parts.

Nearly pure aluminium hydrate is prepared from cryolite. The sodium aluminate obtained in the manufacture of sodium carbonate (see SODII CARBONAS) is treated with milk of lime, resulting in the production of sodium hydrate and a precipitate of calcium aluminate (see SOPA); on dissolving a portion of the latter in hydrochloric acid, chlorides of aluminium and calcium are formed, and this solution, on being digested with another portion of the precipitate, yields more calcium chloride, which remains in solution, and aluminium hydrate; $\text{Al}_2\text{Cl}_6 + \text{Al}_2(\text{O}_2\text{Ca})_3 + 6\text{H}_2\text{O}$ yield $3\text{CaCl}_2 + 2\text{Al}_2(\text{HO})_6$.

Properties.—Aluminium hydrate is “a white, light, amorphous powder, permanent in dry air, odorless and tasteless, and insoluble in water or alcohol; soluble, without residue, in (dilute) hydrochloric or sulphuric acid, and also in solution of potassa or of soda. When heated to redness it loses 34.6 per cent. of water of hydration.”—*U. S.* A portion of the water is given off already at a temperature a little above 100° C. (212° F.), but for expelling the last 10 or 12 per cent. of it a full red heat is required, when *aluminium oxide*, Al_2O_3 , is obtained. Its solution in a mineral acid is not precipitated or colored by hydrosulphuric acid, and shows toward alkalies and alkaline carbonates the behavior described under ALUMEN. When added to a turbid or colored liquid, the impurities suspended and the coloring matter contained therein are precipitated; freshly-precipitated aluminium hydrate (*alumine englée*, Fr.) is best adapted for this purpose; hence its use for the clarification of vegetable juices and the preparation of *lakes*, which consist of aluminium hydrate united with and tinged by pigments.

Tests.—Aluminium hydrate is liable to be contaminated with alkaline carbonate or sulphate and a trace of iron derived from the alum; zinc and other metals can only be present through great carelessness. The allowable limits of these impurities are thus ascertained: “A solution of 1 Gm. of hydrate of aluminium in 30 Cem. of diluted hydrochloric acid should not be colored blue by a drop of test solution of ferrocyanide of potassium (iron), and should not give more than a faint cloudiness with test solution of chloride of barium (limit of sulphate). When dissolved in solution of potassa or of soda it should yield no precipitate with test solution of sulphide of ammonium (zinc or lead). When finely-powdered hydrate of aluminium is boiled with 20 parts of water and filtered, the filtrate should not leave more than a slight residue on evaporation (limit of salts of alka-

lies).”—*U. S.* The presence of calcium compound is determined by dissolving the aluminium hydrate in diluted hydrochloric acid, precipitating the solution with an excess of ammonia, adding to the filtrate ammonium carbonate, and boiling, when carbonate of calcium and of other alkaline earths will be precipitated.

Allied Compounds.—CORUNDUM, *Æ.* Corindon, *Fr.*, Korund, *G.*, is a mineral consisting of Al_2O_3 . It varies in color, forms rhombohedral crystals, is nearly as hard as diamond, and has the specific gravity 3.9. Transparent varieties of it are the gems *ruby* (rubis, *Fr.*, Rubin, *G.*), which is colored red by chromium; the *sapphire* (saphir, *Fr.*, *G.*), which is blue, or if yellow is known as *Oriental topaz*, if green as *Oriental emerald*, and if violet-colored as *Oriental amethyst*. A coarse variety of corundum is known as—

LAPIS SMIRIDIS, *S.* SMYRIS; Emery, *Æ.*; Emeril, Corindon granuleux ferrifère, *Fr.*; Smirgel, Schmirgel, *G.* Its English and French names are derived from Cape Eméri on the island of Naxos, where the mineral has been mined from ancient times. It is also found in other parts of Europe and in the United States. Owing to its hardness, it is largely employed for cutting and polishing glass, metals, and other hard substances, and is prepared for this purpose by crushing under stampers, sifting, and, for delicate operations, by elutriation. Its color varies between gray, bluish, and brown.

The metal *aluminium* was first obtained by Woehler (1827) by fusing aluminium chloride together with potassium. St. Claire-Deville (1854) was enabled to prepare it in larger quantities by heating a mixture of 100 parts of aluminium sodium chloride, 35 parts of sodium, and 40 parts of cryolite. Pure aluminium resembles tin in appearance; its specific gravity varies between 2.50 and 2.79. It is very ductile, melts at about $700^{\circ} C.$ ($1292^{\circ} F.$), is not volatile, and is not tarnished on exposure, even at an elevated temperature; but in the form of powder or thin foil it burns to alumina when heated in oxygen, and slowly evolves hydrogen with boiling water.

Action and Uses.—*Hydrate of aluminium* appears to resemble the oxide of bismuth and also magnesia in its action and uses. Like the former, it is absorbent and protective, and, like the latter, antacid. It is suitable for the treatment of *dyspepsia* and of *diarrhæa* when they depend upon an excess of acid in the digestive canal. In Germany it is used in infantile disorders of the stomach and bowels. It may be given in doses of from 3 to 6 grains (*Gm.* 0.20–0.40). It may be applied externally as a substitute for oxide of zinc, oxide of bismuth, and similar protectives in cases of *intertrigo*, *superficial burns*, etc.

ALUMINII SULPHAS, *U. S.*—SULPHATE OF ALUMINIUM.

Aluminium sulfuricum, *P. G.*—*Sulfate d'alumine*, *Fr.*; *Aluminiumsulfat*, *Schwefelsaure Thonerde*, *G.*

Formula (crystallized) $Al_2(SO_4)_3 \cdot 18H_2O$. Molecular weight 666.

Preparation.—Aluminium sulphate is occasionally found as an efflorescence near volcanoes and upon alum-slate. For medicinal use it should be prepared from aluminium hydrate, which need not be previously dried, by dissolving it in the requisite quantity of dilute sulphuric acid. 6 parts of strong sulphuric acid, diluted with 35 to 40 parts of water, will be sufficient for combining with the aluminium hydrate obtained by the process described under ALUMINII HYDRAS from 19 parts of ammonia alum or 20 parts of potassa alum: the gelatinous hydrate will dissolve quite readily. The solution is filtered, and evaporated until a pellicle begins to form, when the vessel should be removed to a water-bath and the evaporation continued until a dry salt remains. Several soluble and insoluble basic aluminium sulphates being known to exist, an excess of aluminium hydrate should be avoided. Quite as objectionable, or still more so, is an excess of sulphuric acid; the total absence of uncombined acid is readily ascertained by testing the clear solution with sodium hyposulphite, when it should not become turbid by the separation of sulphur, and should not evolve sulphurous acid gas.

For use in the arts sulphate of aluminium is prepared by heating ammonia alum to a dull-red heat, when the ammonium sulphate is decomposed and expelled, leaving anhydrous aluminium sulphate; or it is made from shale and other aluminous silicates, and is known to dyers as *concentrated alum* or *cake-alum*.

Properties.—Sulphate of aluminium may, with some difficulty, be obtained in thin pearly lamellar crystals, but usually forms a white crystalline mass or granular powder. It melts readily in its water of crystallization, and loses it completely when heated to between 150° and $200^{\circ} C.$ (302° and $392^{\circ} F.$), leaving 51.4 per cent. of a light porous mass, consisting of the anhydrous salt, $Al_2(SO_4)_3$. When heated to bright redness, oxygen and sulphuric acid are given off, and alumina is finally left. The salt is quite freely

soluble in water, the solution having an acid reaction to test-paper: according to Poggiale (1843), 100 parts of water dissolve—

At 0°	10°	20°	30°	40°	50°	60°	80°	100° C.
in 86.85	95.8	107.35	127.6	167.6	201.4	262.6	467.3	1132 parts.

Anhydrous aluminium sulphate is less freely soluble in water. The dilute aqueous solution of the crystallized salt is precipitated by alcohol in pearly flakes, having the composition $\text{Al}_2(\text{SO}_4)_3 \cdot 10\text{H}_2\text{O}$, which, according to Hauser (1854), attract water on exposure to a damp atmosphere and are converted into the official salt. This has an acid, styptic, and, at the same time, sweetish taste. Its aqueous solution shows the presence of sulphuric acid by barium chloride; it is precipitated by caustic potassa or soda, the precipitate being soluble in an excess; and this alkaline solution is not affected by sulphuretted hydrogen (absence of zinc, manganese).

Tests.—The salt generally contains a small quantity of sodium or other alkaline sulphate, and often a trace of iron, derived from the alum. The allowable limits of these impurities are thus determined: "A solution of 1 Gm. of the salt in 30 Ccm. of water should not give more than a faint blue coloration with a drop of test solution of ferrocyanide of potassium (limit of iron). If 1 Gm. of the salt be dissolved in 50 Ccm. of water, a slight excess of water of ammonia added, the liquid heated until all odor of ammonia has disappeared, and then filtered, the precipitate well washed with water, and the filtrate and washings evaporated to dryness and gently ignited, the residue should not weigh more than 0.05 Gm. (absence of more than 5 per cent. of sulphates of alkalis)." — *U. S.* The sulphates of sodium and potassium are readily detected by this test, but not ammonium sulphate, which is likely to be present if ammonia had been used in the preparation of aluminium hydrate; more than minute traces of this impurity are detected by adding to a warm strong solution of the salt, contained in a long test-tube, an excess of potassa or soda solution, when the ammonia may be recognized by its odor, its reaction upon moistened red litmus-paper, and by the white vapors produced on the approach of a glass rod previously dipped into hydrochloric or acetic acid.

Other Preparations of Aluminium.—**ALUMINII ACETAS.** Acetate of aluminium, *E.*: Acétate d'alumine, *Fr.*; Aluminium acetat, *G.*, $\text{Al}_2(\text{CH}_3\text{CO}_2)_3 \cdot 4\text{H}_2\text{O}$.—Prepared by dissolving aluminium hydrate in cold acetic acid, or by decomposing aluminium sulphate with lead acetate, and evaporating at a low temperature, it is obtained as a gum-like mass having an acid reaction and a styptic taste. The solution, heated in presence of other salts, is decomposed, with the separation of basic aluminium acetate.

An impure solution of the salt, containing also sulphate of potassium or ammonium, obtained by mixing the aqueous solutions of 6 parts of sugar of lead and 5 parts of alum, and filtering from the precipitated lead sulphate, is extensively employed in dyeing as a mordant and is serviceable as a disinfectant.

LICQUR ALUMINII ACETATIS (*Acetici*, *P. G.*). Solution of acetate of aluminium, *E.*: Soluté d'acétate d'alumine, *Fr.*; Aluminiumacetat-Lösung, *G.*—Dissolve aluminium sulphate 300 parts in water 800 parts; add acetic acid (sp. gr. 1.041) 360 parts; triturate calcium carbonate 130 parts with water 200 parts, and add this mixture slowly and with continued stirring to the first solution; set the whole aside for 24 hours without applying heat, and stir occasionally; then strain, press the precipitate without washing it, and filter the liquid. It is a clear colorless liquid, having the spec. grav. 1.044 to 1.046, a faint odor of acetic acid, an acid reaction, and a sweetish astringent taste. On adding to it one-fiftieth of its weight of potassium sulphate and heating it in a water-bath, it coagulates, but after cooling becomes clear again in a short time. The solution is not colored by hydrosulphuric acid, and on being mixed with twice its volume of sulphuric acid becomes opalescent, but does not produce a precipitate. 20 Gm. of the solution mixed with 20 Gm. of water and a few drops of solution of phenolphthalein should require not less than 9.2 to 9.8 Ccm. of normal potassa solution for producing a red color. On precipitating 10 Gm. of the solution with ammonia, .24 to .25 Gm. of alumina should be obtained, proving 7.5 to 8 per cent. of basic aluminium acetate.—*P. G.*

The formula of this compound is $\text{Al}_2(\text{HO})_2(\text{C}_2\text{H}_3\text{O}_2)_4$; its molecular weight 324. The above process is more simple, and yields more uniform results, than the one devised by Hager (1871), in which aluminium sulphate was decomposed by basic lead acetate.

ALUMINII NITRAS. Nitrate of aluminium, *E.*: Azotate d'alumine, *Fr.*; Salpetersaure Thonerde, *G.*—Formula $\text{Al}_2(\text{NO}_3)_6 \cdot 18\text{H}_2\text{O}$. Molecular weight 750. The gelatinous aluminium hydrate obtained from 33 parts of potassa alum or from 31.5 parts of ammonia alum, when dissolved in 20 parts of official nitric acid, yields a solution containing 26 parts of this salt; diluted with water to 260 parts, the solution contains 10 per cent. of the salt, which is with difficulty obtained in deliquescent crystals, soluble also in alcohol.

CHLORIDE OF ALUMINIUM, in an impure state, has been used to some extent. A solution sufficiently pure for disinfecting purposes is obtained by mixing the solutions of 2 parts of alum and 1 part of anhydrous calcium chloride and filtering from the precipitated calcium sulphate.

The pure salt, Al_2Cl_6 , is best prepared by dissolving aluminium hydrate in hydrochloric acid and evaporating carefully, when crystals containing $12\frac{1}{2}\text{H}_2\text{O}$ are obtained, which are readily soluble in water and alcohol and are decomposed by heat. In the anhydrous state, however, aluminium chloride is volatile.

ULTRAMARINE, *E. Fr.*: Outremer, *Fr.*: Ultramarin, *G.*, is a pigment which was formerly obtained from *lapis-lazuli* or *lazulite*, a mineral found chiefly in Asia, and composed of sulphur compounds and silicates of aluminium and sodium. The preparation of artificial ultramarine was first made known by C. Gmelin in 1828, and about the same time discovered by Guimet. Shortly afterward it was manufactured on a large scale, and its consumption, which was 3,500,000 kilos in 1862 and 8,500,000 kilos in 1872 (R. Hoffmann), was estimated by R. Wagner in 1880 to be 30,000,000 kilos. It is prepared by heating in crucibles a mixture of clay, sodium sulphate, and charcoal nearly to a white heat for several hours. A white compound is first formed, called *white ultramarine*; this passes into *green ultramarine*, which is employed in the arts to a certain extent, but mostly converted into *blue ultramarine*, usually by roasting it in the presence of sulphur. By increasing the amount of silica in the first operation the product acquires a more purplish tint, and by treating these products at an elevated temperature with acids *violet* and *red* ultramarines are prepared. All these compounds are decomposed by acetic acid, which does not affect lazulite. Mineral acids decompose them, separating gelatinous silicic acid, sulphur, and hydrosulphuric acid; red ultramarine evolves sulphurous acid gas on being treated with acids. The exact composition is still unknown. Ultramarine blue is largely used for whitening—that is, neutralizing—the yellow tint of sugar, starch, paper, etc.

Medical Uses.—On account of the acid taste of this preparation it is seldom used alone internally, but is either combined with zinc or is saturated with gelatinous hydrate of aluminium and mixed with the soluble constituents of benzoin. As a topical application a solution of 1 part of the sulphate in about 20 parts of water has been used to promote the healing of ulcers and to correct the fetor of discharges, especially in certain cases of *leucorrhœa* and chronic *dysentery*, and to cure *ulcers* of the cervix uteri. The addition of benzoin to the solution for these purposes also has been recommended. In a concentrated state sulphate of aluminium is a powerful astringent, and in some degree a caustic also. It has been used for destroying exuberant growths, and even *cancerous* tumors. Its free acid corrodes textile fabrics and metals. To mitigate this effect the excess of acid has been neutralized by zinc, and a sulphate of aluminium and zinc formed, which in a pure state acts as a caustic, and either in this condition or mitigated with glycerin may be used to repress fungous granulations, to destroy imperfectly organized tissues and certain hypertrophies, such as *cancers*, vascular *navi*, and *polypoid* growths, and to stimulate tissues *chronically inflamed*, as those of the nostrils, throat, vagina, rectum, urethra, etc. This double salt has been used for injecting dead bodies, which it preserves unchanged for a long time.

Acetate of aluminium resembles alum in its general astringent action, contracting the tissues and restraining secretion. When 30 or 40 drops of a solution of 1 part of the salt to 8 of water are taken internally a sense of warmth is excited in the stomach, and if the doses are reiterated some fullness of the head and confusion of the senses result. Added to putrescible mixtures, it restrains or prevents putrefaction. It has been used for the same purposes as the sulphate of aluminium, and particularly to deodorize fetid secretions of sweat, pus, mucus, etc. As a lotion or injection 1 part of a 10 per cent. solution mixed with 100 or 200 parts of water may be employed.

The *chloride* is said to be closely analogous to the acetate of aluminium in its action, and may be used for the same purposes. Under the name of *chloralum* a preparation which contains only from 10 to 15 per cent. of chloride of aluminium, besides arsenic and copper as impurities, and which is also said to be a compound of the sulphate and chloride, has been much used of late years as a disinfectant and deodorizer, and as a hæmostatic when applied on cloth or cotton impregnated with it. The cheapness of chloride of aluminium and its freedom from odor fit it well for use in hospitals and private houses.

Nitrate of aluminium has been used in a solution containing 15 or more grains to an ounce (Gm. 1 in Gm. 30) of water as a lotion for the relief of *pruritus vulvæ*.

AMBRA GRISEA.—AMBERGRIS.

Ambra cinerea.—*Ambre*, *Ambre gris*, *Fr.*; *Amber*, *Graue Ambra*, *G.*

Origin.—Ambergris is regarded as a morbid product of the sperm whale, *Physeter macrocephalus*, *Linné*, and is found in its intestines as well as floating on the sea. One whale has been known to yield 750 pounds of this product (*Amer. Jour. Pharm.*, 1859, p. 183).

Description.—It comes in irregular pieces, varying considerably in size, is opaque,

of a gray or gray-brown color, with lighter and darker-colored streaks and spots, lighter than water, friable in the cold, but softening when held in the hand. It is of a waxy appearance, fusible in hot water, mixing with melted fats, and soluble in volatile oils, ether, and hot alcohol. It has a peculiar fragrance, is nearly tasteless, and on ignition leaves but little ash.

Composition.—Ambergris consists mainly (about 85 per cent.) of a fatty substance resembling cholesterol, which Pelletier and Caventon have named *ambreïn*. It crystallizes from hot alcohol in white, shining, tasteless, and inodorous needles, which fuse near 35° C. (95° F.). The remaining constituents, according to John (1818), are some balsamic matter, chloride of sodium, benzoic acid (?), and coloring matter.

Adulterations.—Adulterated and fictitious ambergris can be readily recognized by different physical properties.

Pharmaceutical Uses.—*Tinctura ambre* of the French Codex is prepared by macerating 10 parts of ambergris, which, according to Stanislas Martin, should be finely powdered by trituration with washed sand, in 100 parts of 80 per cent. alcohol. It is often used for fixing very volatile delicate perfumes.

Medical Action and Uses.—Ambergris, like other strongly odoriferous animal products, has been believed to possess a stimulant action upon the nervous and circulatory systems, with a special direction to the generative organs. It was used in *low fevers* and in spasmodic disorders, especially of the *hysterical* sort, and often associated with musk, castor, and valerian. It was prescribed in substance in the dose of from 5 to 20 grains (Gm. 0.30–1.30), or more frequently in ethereal solution. It is seldom if ever employed at the present day as a medicine, but it enters into various perfumes.

AMBROSIA.—RAGWEED.

Ambrosie, Fr.; *Traubenkraut*, G.

Nat. Ord.—Compositæ, Senecionideæ.

Description.—This genus comprises coarse-looking rough or hairy weeds, with mostly opposite leaves, and with inconspicuous, yellowish, staminate flower-heads arranged in elongated racemes or spikes, at the base of which one to three staminate flowers are situated in the axils of the leaves. The following two, growing in waste places in North America, have been used:

AMBR. TRIFIDA. *Linné*, attains a height of 8 feet (2.4 M.) or more, and has entire oval or usually deeply-trilobed leaves with the lobes oval lanceolate and serrate.

AMBR. ARTEMISLEFOLIA. *Linné*, also known as *bitterweed*, *hogweed*, *Roman wormwood*, is about 3 feet (.9 M.) high: its leaves are thinner, smoother, and of a lighter green than the preceding, and twice pinnatifid, with the divisions lanceolate. It grows southward to Brazil.

Both species have a slight and rather fetid odor and a bitter and slightly astringent taste. *Ambr. maritima*, *Linné*, of Southern Europe, which resembles the last, but is grayish-pubescent, has an agreeable odor and an aromatic bitter taste.

The constituents of these plants have not been investigated.

Medical Uses.—The two species of *Ambrosia*, like other bitter herbs, have been employed in the cure of *intermittent fever*. Its astringency has caused it to be used to moderate *discharges* of blood and mucus and to palliate mercurial *salivation*; the stimulant qualities attributed to it are supposed to be shown in the *typhoid state* of febrile affections. An infusion of the tops may be made with 3 or 4 drachms to a pint of water (Gm. 10–15 in Gm. 500).

AMMONIACUM, U. S., Br., P. G.—AMMONIAC.

Gummi-resina ammoniacum.—*Ammoniacum*, E.; *Ammoniaque*, *Gomme-resine ammoniacque*, Fr.; *Ammoniakgummi*, G.

A gum-resinous exudation from *Dorema Ammoniacum*, *Don*. Bentley and Trimen, *Med. Plants*, 129, 130.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—The plant, which is of a striking appearance, grows to the height of 6 or 7 feet (2 M.); its leaves are all radical; the hollow stem bears a few long leaf-sheaths, and divides toward the apex into about sixteen ascending branches, upon which the small globular short-stalked umbels are borne, the inflorescence forming a paniculate raceme. The root is rich in milk-juice, which rapidly diminishes in quantity when, in

about the fifth year, the stem is produced, after which the plant perishes. The gum-resin exudes from the stem and flowering branches from punctures produced by insects; an inferior kind exudes near the base of the stem among the remnants of the leaf-sheaths, and in the soil considerable quantities of hardened milk-juice are often found which has exuded from fissures in the root produced during the hot season.

This species of *Dorema* prefers a silicious soil, and occurs abundantly in the deserts and barren regions of Persia and Tartary, usually accompanied by *Ferula Scorodisma*, the Persian asafetida-plant, but growing farther north and north-east than the latter, extending to the southern shore of the Sea of Aral and nearly to the south-eastern extremity of the Caspian Sea, while its southern limits are near Bahziran in Southern Khorassan (Borszezow, 1860).

It is not impossible that *Dorema Aucheri*, *Boissier*, a West-Persian plant, but less frequent than the former, may yield some of the commercial ammoniac; but *D. robustum*, *Loflus*, which is united with the species mentioned by Boissier, affords a gum-resin distinct from ammoniac (*Pharmacographia*).

Description.—The best quality of ammoniac exists in dry tears from $\frac{1}{16}$ to $\frac{1}{2}$ inch (1.5–12 Mm.) in diameter, which are globular or irregularly roundish in shape, often more or less flattened, externally of a pale brownish-yellow and internally milk-white. Their fracture is somewhat conchoidal and of a waxy lustre. The tears sometimes coalesce and form irregular masses, which when broken show the outlines of the individual grains, without any intervening darker-colored mass.

Cake-ammoniac is an inferior quality, and consists of the tears imbedded in the brown gum-resinous mass obtained from the base of the stem; and a kind is occasionally seen in which the tears are not larger than a pin's head and few in number, the greatest bulk consisting of a plastic brown or greenish-brown mass mixed with vegetable fragments and earthy matter.

Ammoniac softens by the heat of the hand and when triturated in a mortar. It has a peculiar odor, which becomes stronger after heating, and a bitter, acrid, and nauseous aromatic taste. Chlorinated lime imparts to it an orange and potassa a yellowish color. On being triturated with water it readily yields a white emulsion, which, on the addition of caustic soda, acquires a yellow, and finally a brown, color. In contact with hydrochloric acid, ammoniac is not changed in color even when heated to 60° C. (140° F.). Warm concentrated sulphuric acid dissolves ammoniac with a blood-red color, and the solution shows no fluorescence on dilution with water and on the addition of alkali (Schlickum). For medicinal purposes the tears only should be used.

African ammoniac, obtained from *Ferula tingitana*, *Linne*, is not found in our market; it has a faint but more agreeable odor, somewhat like that of benzoin, and an acrid but not bitter taste. Moss (1873) found in it 68 per cent. of resin, 9 per cent. of soluble gum, 19 per cent. of insoluble matter, and 4 per cent. of moisture and volatile principles. Umbelliferon was obtained from it by Hirschsohn (1875). Goldschmiedt (1878), by fusing with potassa, prepared resorcin and an acid, $C_{10}H_{10}O_6$, the aqueous solution of which strikes a beautiful red color with ferric chloride; officinal ammoniacum does not yield such a compound.

Composition.—According to the analyses of Bucholz, Hagen, and Braconnot, ammoniac contains from 1.8 to 4 per cent. of volatile oil, 70 to 72 per cent. of resin, 18 to 22 per cent. of gum, $1\frac{1}{2}$ to 4 per cent. of bassorin or gluten, and about 6 per cent. of moisture. The volatile oil, of which usually only between $\frac{1}{2}$ and 2 per cent. is obtained, is free from sulphur (Moss, 1873), and its solution in alcohol acquires a reddish hue with ferric chloride (*Pharmacographia*). According to Przecziszewski (1861) the gum is nearly identical with gum-arabic, and the resin is a mixture of an acid and an indifferent resin, of which the one insoluble in ether dissolves readily in volatile and fixed oils.

Fused with caustic potassa, Hlasiwetz and Barth obtained (1864) resorcin and oxalic acid and a volatile fatty acid. On the dry distillation of ammoniac Sommer failed to obtain umbelliferon.

Pharmaceutical Uses and Preparations.—Ammoniac may be powdered after exposure to cold, or, after having been dried over lime, in the same manner as asafetida, the powder should be preserved over lime. It forms an ingredient in Emplast. ammoniaci, *U. S.*; Empl. ammoniaci cum hydrargyro, *U. S.*, *Br.*; Empl. galbani, *Br.*; Mistura ammoniaci, *U. S.*, *Br.*; Pil. scillæ comp., Pil. ipecacuanhæ cum scilla, *Br.*

Physiological Action.—Ammoniac has always been regarded as a stimulant of the circulation and nutrition. Large doses of it have been said to produce an eruption on

the skin, besides vomiting, colic, and diarrhœa. In a plaster it occasions a papular eruption. The above effects have been questioned, but are too well established clinically to be set aside by any experiments upon healthy subjects. It is probable that they depend chiefly upon the volatile oil and partly upon the resin of ammoniac.

Medical Uses.—The most important internal use of ammoniac is in the treatment of chronic pulmonary catarrh, or *bronchitis*, in which the secretion is excessive and expectoration difficult and there is an absence of fever. The condition of the bronchia in such cases includes passive congestion, excessive secretion, and feeble action of the circular muscles; all stimulants tend to remove this condition, and those especially which are excreted through the lungs, including the whole resinous class. The alleged benefits of ammoniac in *asthma* are probably most demonstrable in asthma associated with pituitous and other analogous forms of bronchitis. It tends to remove the exciting cause of the nervous paroxysm, but probably has a minor influence upon the spasmodic element itself. There is a certain acrimony about ammoniac which perhaps explains the fact that its continued use is apt to render the bronchial and laryngeal mucous membrane dry and irritable, and therefore the medicine, if long continued, may increase coughing after having lessened it. It is said to be very useful in *hysterical asthma*, but with the qualification that it should be associated with asafetida. This gives the credit of the cure to the asafetida, which is alone entitled to it. In bronchial affections ammoniac may be administered in the form of the official mixture or in that of the compound pills of squill. It has sometimes been employed in chronic catarrh of the *urinary passages*. Externally, ammoniac is used as a rubefacient in plasters for the relief of chronic *rheumatism*, especially of the muscular form, for promoting the cure of bronchial *catarrh*, chronic *pleurisy*, and various other affections requiring a superficial and sustained irritation of the skin. In some of these cases the plaster of ammoniac with mercury is preferable on account of the specific action of the metal, which is very apt to display itself. The *dose* of ammoniac is from 10 to 30 grains (Gm. 0.60–2.00).

AMMONII BENZOAS, U. S.—BENZOATE OF AMMONIUM.

Ammonix benzoas, Br.; *Ammonium benzoicum*, *Benzoas ammonicus*.—*Benzoate d'ammoniaque*, Fr.; *Ammoniumbenzoat*, *Benzoësaures Ammonium*, G.

Formula $\text{NH}_4\text{C}_7\text{H}_5\text{O}_2$. Molecular weight 139.

Preparation.—Take of Benzoic Acid 2 ounces; Solution of Ammonia 3 fluidounces or a sufficiency; Distilled Water 4 fluidounces. Dissolve the benzoic acid in 3 fluidounces of the solution of ammonia, previously mixed with the water; evaporate at a gentle heat, keeping ammonia in slight excess, and set aside that crystals may form.—Br.

The formula of the U. S. P. 1870 was identical with the foregoing. During the evaporation of the solution considerable ammonia is given off, and an acid ammonium benzoate would be left. To obtain the neutral salt it is necessary to add sufficient ammonia until an alkaline reaction is obtained, when the liquid is set aside to crystallize, and to avoid heat while drying the crystals.

Properties.—Benzoate of ammonium crystallizes in colorless or white thin four-sided laminae, having a slight odor of officinal benzoic acid, and a saline somewhat bitter taste, with a slight acid after-taste; it is readily soluble in alcohol and water, requiring 5 parts of water or 28 parts of alcohol at 15° C. (59° F) and 1.2 parts of boiling water or 7.6 parts of boiling alcohol (*U. S. P.*). On being heated it fuses, gives off vapors of benzoic acid and ammonia, and finally evaporates, without leaving any residue. Its neutral solution gives, with ferric salts, a bulky light brownish-yellow (yellowish, Br., flesh-colored, *U. S.*) precipitate, evolves ammonia when heated with potassa, and, if it be not too dilute, deposits benzoic acid when acidulated with hydrochloric acid. The acid salt is less soluble, requiring about 60 parts of water and 12 parts of alcohol.

The *purity* of the salt is ascertained by its not yielding any carbonaceous mass when heated or leaving a non-volatile residue when ignited. Its diluted solution, acidulated with nitric acid, should not be precipitated by chloride of barium or nitrate of silver (absence of sulphate and chloride).

Medical Action and Uses.—The action of benzoate of ammonium in the system appears to be much the same as that of benzoic acid alone, and the salt possesses over the acid only the advantage of greater solubility. Its chief uses are treated of in the article on BENZOIC ACID. In addition it may be stated that this preparation has been used in chronic *gout* and *gravel*. *Dose*, from 5 to 20 grains (Gm. 0.30–1.30), which may be given best in a mixture.

AMMONII BROMIDUM, *U. S.*, *Br.*—BROMIDE OF AMMONIUM.

Ammonium bromatum, P. G.—*Bromure d'ammonium*, Fr.; *Bromammonium*, *Ammonium bromid*, G.

Formula NH_4Br or AmBr . Molecular weight 97.8.

Preparation.—Bromide of ammonium may be prepared by neutralizing hydrobromic acid with ammonia or ammonium carbonate, and evaporating the solution. It may also be obtained by first preparing ferrous bromide from 4 parts of bromine, 2 parts of iron, and 16 parts of water, and precipitating the greenish solution with a slight excess (about 9 parts) of ammonia-water, when bulky ferrous hydrate is deposited. Or the above solution of ferrous bromide is mixed first with 1 part of bromine, and afterward with ammonia in excess (about 11 parts), when a dense ferroso-ferric hydrate is precipitated, which may be readily washed with water; the filtrate is evaporated and allowed to crystallize or the salt is granulated.

But, according to Charles Rice (1873), ammonium bromide prepared by the processes just mentioned is prone to decomposition, bromine being gradually liberated. This change does not occur if the salt is prepared as follows: The solutions of 4 troyounces of bromide of potassium in 6 fluidounces of boiling water, and of 3 troyounces of ammonium sulphate in $4\frac{1}{2}$ fluidounces of boiling water, are mixed while boiling hot, and when cool $1\frac{1}{2}$ fluidounces of alcohol are added. After 24 hours the clear liquid is decanted from the crystalline deposit of potassium sulphate, the latter washed with a little 18 per cent. alcohol, and the filtrate evaporated as before. Prepared in this manner, the salt contains minute quantities of ammonium and potassium sulphate, the presence of which is avoided by sublimation. For this purpose an intimate mixture of well-dried potassium iodide (20 parts) and exsiccated ammonium sulphate (11 parts) is introduced into a retort with a wide and rather short neck, and heated in a sand-bath.

When bromine and ammonia are brought into direct contact in the presence of water, bromide of ammonium is formed and nitrogen escapes; $3\text{Br}_2 + 8\text{NH}_3 = 6\text{NH}_4\text{Br} + \text{N}_2$. According to Dr. Pile (1874), the violence of the reaction is best controlled by keeping the two liquids at first separate from each other by a layer of distilled water; he manipulates as follows: 1 pound of bromine is introduced into a 5-gallon stone jar, under a layer of half a gallon of water; stronger water of ammonia is then added in quantities of 2 or 3 ounces at a time, so that it will float upon the surface of the water. The jar is covered with a glass plate, and after the reaction has subsided more ammonia is added. Should the reaction become too violent, it must be moderated by placing the jar in cold water. When the color of bromine has entirely disappeared and the ammonia is finally in slight excess, the solution is evaporated. If the salt is desired in crystals, the solution is concentrated and set aside without stirring it.

Properties.—It is either in white granular, cubical, or in larger colorless prismatic crystals, which have a neutral reaction to test-paper and a pungent saline taste. On exposure to air the salt gradually becomes damp and acquires a yellow color and acid reaction. When heated it sublimes without melting. It is soluble in 1.5 parts of water and in 150 parts of alcohol at 15°C . (59°F .), in .7 part of boiling water, and in 15 parts of boiling alcohol (*U. S.*). Ether dissolves a minute quantity of the salt. Chlorine-water, carefully added so as to avoid an excess, liberates from the aqueous solution of the salt bromine, which dissolves in disulphide of carbon or in chloroform with a yellow, reddish-yellow, or yellowish-brown color, which is free from violet tint (iodine).

Tests.—It may be regarded as pure if, on being heated upon platinum-foil, a non-volatile residue is not left behind. A small portion of the salt placed upon a porcelain tile should not at once acquire a yellow color on the addition of a few drops of diluted sulphuric acid (absence of bromate). Its solution should not be precipitated by chloride of barium (absence of sulphate and phosphate). The solution, mixed with a little mucilage of starch, should not show a blue color (which would indicate iodine) if a drop of chlorine or bromine-water be added on top. If 10 grains of the salt are dissolved in water, and the solution is well mixed with a solution of 17 grains of nitrate of silver, a curdy yellowish precipitate will appear, and the clear liquid should be merely rendered cloudy on the further addition of nitrate of silver. A white precipitate would indicate the presence of ammonium chloride, which requires a larger quantity of silver nitrate for complete precipitation than the bromide; and if no cloudiness is produced, iodide of ammonium may probably be present, which, from its greater molecular weight, is completely precipitated by less nitrate of silver. The precipitate of 10 grains of ammonium bromide by sufficient silver nitrate, after washing with water acidulated with nitric acid

and drying, will weigh 19.17 grains (1.917 Gm. from 1 Gm. AmBr.). The presence of chloride of ammonium would increase the weight of the silver precipitate. The allowable limits of the impurities are thus determined: "On adding to 1 Gm. of the salt dissolved in 20 Ccm. of water 5 or 6 drops of test solution of chloride of barium, no immediate cloudiness or precipitate should make its appearance (limit of sulphate). If 3 Gm. of the well-dried salt be dissolved in distilled water to 100 Ccm., and 10 Ccm. of this solution treated with a few drops of test solution of bichromate of potassium, and then volumetric solution of nitrate of silver be added, not more than 31.4 Ccm. (31.1 Ccm., *P. G.*) of the latter should be consumed before the red color ceases to disappear on stirring (absence of more than 3 [2, *P. G.*] per cent. of chloride)." — *U. S.* A solution of .5 Gm. of the salt in 5 Ccm. of water, mixed with 1 drop of solution of ferric chloride and agitated with chloroform, should not impart a violet color to the latter (iodide). — *P. G.*

Physiological Action.—Bromide of ammonium in *almost* every respect has the same action as bromide of potassium. In animals it induces capillary anemia and venous congestion of the brain, thereby producing drowsiness and anaesthesia, but at the same time a liability to clonic (passing into tonic) convulsion. It does not appear to restrain the movements of the heart. According to Chéron and Fouques, this salt moderates reflex action and stimulates the periphery of the nervous system. This salt has a more acrid taste and is more irritating than potassium bromide. It obtunds the sensibility of the mouth and pharynx, as well as general reflex sensibility. It produces a papular eruption upon the skin, and its prolonged use brings on a sort of hebetude or intellectual dulness. Its unpleasant taste and irritating qualities render it less convenient for administration than bromide of potassium.

Medical Uses.—Bromide of ammonium, in conjunction with potassium bromide, has been used extensively in the treatment of *epilepsy*; but while it is held by some authorities that this association diminishes the bad, while it increases the good, effects of the combination, other observers have failed to recognize in it any advantage, while they object to the unpalatable taste of the bromide of ammonium—a grave defect in a medicine which must be continuously used for a long time in the treatment of disease. The weight of authority, however, appears to be in favor of the opinion that 10 grains of bromide of potassium with 3 or 5 grains of bromide of ammonium produce a greater sedative influence than 12 or 15 grains of either of them administered separately. This salt has been successfully employed in some cases of *delirium tremens*. It has also been recommended as possessing remarkable virtues in *whooping cough* during the spasmodic stage of the disease, and the success of bromide of potassium in the same affection supports the recommendation. It has been particularly eulogized by Kormann in Germany (*Med. News, etc.*, xxxix. 473) and Grinnell in this country (*ibid.*, xl. 294), but without any statement of the duration of the disease under its use. Probably a combination of the two salts would be more efficacious than either alone. In acute articular *rheumatism* this medicine has been supposed to exert a favorable influence; but since it was first proposed 8 or 10 years have elapsed without eliciting any confirmatory experience. The intolerable itching of *prurigo* is sometimes strikingly diminished by it when it is given in doses of 10 grains three times a day. It has been recommended to prevent *menorrhagia*.

Dose, for adults, from 5 to 30 grains (Gm. 0.30–2.00) three times a day; for children, from 1 to 5 grains. It is conveniently administered in a bitter infusion, and especially in hop tea.

AMMONII CARBONAS, *U. S.*—CARBONATE OF AMMONIUM.

Ammoniac carbonas, Br.; *Ammonium carbonicum*, P. G.; *Carbonas ammonicus*, *Sal volatile siccum*, *Alkali volatile*.—*Volatile salt*, E.; *Carbonate d'ammoniaque*, *Alkali volatil concret*, *Sel volatil d'Angleterre*, Fr.; *Ammoniumcarbonat*, *Kohlensaures Ammonium*, *Flüchtiges Laugensalz*, *Reines Hirschhornsalz*, G.

Formula $\text{NH}_4\text{HCO}_3 \cdot (\text{NH}_4)\text{NH}_2\text{CO}_2 = \text{N}_3\text{H}_{11}\text{C}_2\text{O}_5$. Molecular weight 157.

Origin.—Ammonium carbonate was first prepared by Raymund Lull, in the thirteenth century, by the distillation of putrid urine, which contains the normal carbonate, $(\text{NH}_4)_2\text{CO}_3$, formed from urea, CON_2H_4 and $2\text{H}_2\text{O}$, water. It was subsequently obtained by the dry distillation of horn, bones, blood, and other animal matters, and for a long time purified by resubliming this crude product in the presence of animal charcoal. In the fifteenth century Basilius Valentinus observed its production from sal ammoniac and potassium carbonate, in place of which afterward chalk was employed. At present it is largely manufactured by modifications of this process.

Preparation.—A mixture of powdered sal ammoniac with twice its weight of chalk, or of 4 parts each of ammonium sulphate and chalk with 1 part of charcoal, is gradually heated to dull redness in an iron or earthen retort, the vapors being passed through an iron pipe into a leaden chamber, where they condense. The chalk is used in excess to prevent sublimation of undecomposed chloride of ammonium, which would otherwise be apt to contaminate the product. It is then purified by resublimation from iron vessels. The reaction results in the formation of chloride (or sulphate) of calcium and neutral carbonate of ammonium, which on condensation is converted into a salt of the above composition, water and ammonia being given off; $4\text{NH}_4\text{Cl} + 2\text{CaCO}_3$ yield $2\text{CaCl}_2 + \text{N}_2\text{H}_{11}\text{C}_2\text{O}_5 + \text{NH}_3 + \text{H}_2\text{O}$. The ammonia is utilized either by passing the uncondensed vapors into water or through a cylinder filled with coke which is impregnated with dilute sulphuric acid, resulting in the formation of ammonium sulphate. Barium carbonate may be employed in place of chalk, and is advantageously used with ammonium chloride, when barium chloride is obtained at the same time. The ammonium salts used being almost exclusively those obtained from coal-gas liquor, the first sublimate contains tarry products, from which it is freed by resublimation. Nearly 600,000 pounds were annually imported into this country previous to 1878; since that time, between 300,000 and 500,000 pounds.

Properties.—Carbonate of ammonium is found in commerce in white crystalline translucent masses, having a strong ammoniacal odor, an alkaline reaction, and a pungent saline and caustic taste. Exposed to the air, it parts with ammonia and carbonic acid gas, becomes opaque, and falls into a white powder of acid carbonate of ammonium, NH_4HCO_3 ; this salt is likewise obtained by washing the powdered official carbonate with a little cold water, which dissolves chiefly ammonium carbamate. Such a solution begins to evolve gas when heated to 47°C . (116.6°F .), and in larger quantity at 55°C . (131°F .). Divers (1870) found the official salt to be soluble in 1.5 parts of water at 65°C . (149°F .), and in 4 parts of water at 15°C . (59°F .), and the latter solution to give off carbonic acid gas when heated to 75°C . (167°F .); at 85°C . (185°F .) also ammonia, which may be partly condensed as acid carbonate; at 100°C . (212°F .) the whole of the ammonia salt is volatilized. Dilute solutions require to be heated to a higher temperature before gas is given off. Alcohol dissolves ammonium carbamate, and on being heated yields a sublimate of this salt.

Composition.—Of the formulas given above, the last one is purely empirical, while the first represents the salt as a compound of 1 molecule of acid ammonium carbonate with 1 of ammonium carbonate, from which a molecule of water has been separated. The last mentioned compound is regarded as the ammonium salt of carbanic acid (which is unknown in the isolated state), and hence is called *ammonium carbamate*, the formula of which is $\text{NH}_4\text{NH}_2\text{CO}_2$. In its pure state this forms tabular crystals, is deliquescent, volatilizes completely at 59°C . (138.2°F .), with decomposition into ammonia and carbonic acid gas, and in aqueous solution is soon converted into normal ammonium carbonate; the solution of the official salt, therefore, contains a mixture of neutral and acid ammonium carbonate.

The salt formerly in the market, which was prepared from animal matters, closely resembled the official salt, but had the composition $\text{N}_4\text{H}_{16}\text{C}_3\text{O}_8 = 2\text{NH}_4\text{HCO}_3 \cdot \text{NH}_4\text{NH}_2\text{CO}_2$; according to Divers, it was a mixture of the above salt with acid ammonium carbonate.

Tests.—Carbonate of ammonium should be completely volatilized without charring when heated upon platinum-foil (absence of organic matters and non-volatile salts). It should dissolve in diluted acids without residue, and this solution should be free from empyreumatic odor. "If 1 Gm. of the salt be supersaturated with diluted sulphuric acid, then diluted to 20 Ccm. with distilled water, and treated with a few drops of test solution of permanganate of potassium, the color should not be perceptibly changed by standing for 5 minutes at the ordinary temperature (absence of empyreumatic substances)."—*U. S.* "1 Gm. of the salt, on being supersaturated with nitric acid and evaporated to dryness by means of a water-bath, should leave a colorless (white) residue, which at a higher heat volatilizes completely."—*P. G.* Empyreumatic products impart a yellow or brown color to the residue. Hyposulphite of ammonium, which may be present from the decomposition of the sulphate during sublimation, is detected by the brown color produced on adding to the aqueous solution of the salt first an excess of solution of silver nitrate and afterward of nitric acid. After dissolving the salt in a slight excess of diluted nitric acid it should not be precipitated by chloride of barium (sulphate), nitrate of silver (chloride), or sulphuretted hydrogen (metals). Traces of iron may frequently be detected in this solution by ferrocyanide or sulphocyanide of potassium. The presence of ammonium bicarbonate is indicated by the change of the translucent mass into an opaque pul-

verulent condition. Occasionally the bicarbonate has been observed (see *American Journal of Pharmacy*, 1874, p. 540) in translucent solid masses mixed with the official article. In this condition it has but a faint odor of ammonia, and dissolves slowly in water at the ordinary temperature, giving off carbonic acid gas.

59 grains of carbonate of ammonium dissolved in 1 ounce of distilled water will be neutralized by 1000 grain-measures (*Br.*) or 2.95 Gm. of the salt by 50 Ccm. of the volumetric solution of oxalic acid (*U. S.*).

Pharmaceutical Uses and Preparations.—Carbonate of ammonium reacts with the salts of nearly all inorganic and organic bases, with the exception of sodium and potassium, and is therefore incompatible with such salts. Prescribed with syrup of squill or similar preparations, the annoyance caused by the evolution of carbonic acid gas is best overcome by triturating in a mortar the carbonate with a little of the syrup, adding the latter gradually, if admissible, alternately with water or a tincture. The generation of carbonic acid gas in many reactions renders it necessary to triturate the ingredients of pill masses containing carbonate of ammonium with some strong alcohol until the reaction has been completed, when the excipient may be added. The salt is used in making *Ferri et ammonii tartras*, *U. S.*; *Liquor ammon. acetat.*, *Spir. ammon. arom.*, *U. S.* *Br.*

AMMONII BICARBONAS, NH_4HCO_3 , is obtained by treating the powdered official carbonate of ammonium with about twice its weight of water, when carbamate will be dissolved, or by keeping the former for two weeks under a bell-glass over sulphuric acid and slaked lime, when the carbamate will evaporate, being decomposed into carbonic acid gas, CO_2 , and ammonia, NH_3 . Bicarbonate of ammonium is a white powder, when perfectly dry free from ammoniacal odor, of a cooling saline taste, insoluble in alcohol, but soluble in 8 parts of water at 15°C . (59°F .); the solution, heated to 36°C . (96.8°F .), begins to give off carbonic acid gas. From a concentrated solution clear rhombic prisms of the salt may be obtained. Vogler (1878) ascertained that the salt is not permanent in the air, but is slowly volatilized, with the production of an ammoniacal odor.

LIQUOR AMMONII CARBONICI and LIQUOR AMMONII CARBONICI PYRO-OLEOSI, *P. G.*, 1872, are solutions of 1 part of carbonate or of pyro-oleous carbonate of ammonia in 5 parts of distilled water.

AMMONII CARBONAS PYRO-OLEOSUS, s. *Ammonium carbonicum pyro-oleosum*, *P. G.*, 1872, *Sal volatile cornu cervi*.—32 parts of carbonate of ammonium are thoroughly incorporated with 1 part of ethereal animal oil.

Physiological Action.—*On Animals:* In poisonous doses carbonate of ammonium, when given to dogs by the stomach, produces retching and vomiting, followed first by general convulsions, and then by tetanoid rigidity and death, after which the stomach is found actively congested and inflamed and its epithelium softened. The blood in the veins is either liquid or but slightly coagulated. When the salt is introduced into the connective tissue similar symptoms and lesions are produced, including the inflammatory alterations of the gastric mucous membrane. It does not render the urine alkaline. 15, and even 25, grains of it have been injected into the veins of dogs without notable result, except a transient spasm of the abdominal muscles. It is remarkable that the salt does not appear to undergo decomposition, nor does it cause any free ammonia to be exhaled with the breath or from the blood. This fact is the more remarkable since carbonate of ammonium mixed with blood no longer living becomes decomposed. The tetanoid spasms above referred to are very marked when the agent acts through the blood, and there is a momentary suspension of the inspiratory act, which is followed by rapid breathing. Section of the vagi, after the rapid breathing has commenced, does not occasion the labored action which is observed in animals not poisoned after this operation. When the section is performed before the administration of the salt the primary arrest of respiration is prevented, but not the subsequent hurried breathing. These phenomena are ascribed (Lange) to the production by the ammonia of an abnormally excited action of the respiratory centre in the medulla oblongata, which under normal conditions is but transiently or not at all stimulated by inspiratory impulses conducted through the par vagum to the brain.

On Man: The direct effect of carbonate of ammonium when taken in doses of from 5 to 10 grains is to cause some increase of the fulness and force of the pulse and a sense of tightness about the head, sometimes with throbbing. It is also said to increase the temperature of the body during health, and excite the secretions of the skin, kidneys, and bronchia. It readily enters the blood, increasing its alkaline reaction, and escapes by the breath and sweat, and still more by the urine. In doses of from 10 to 20 grains, it excites vomiting. In still larger doses it occasions symptoms of inflammation in the throat, gullet, and stomach, tetanoid convulsions, and death. In a case which proved

fatal intense inflammatory lesions were found in the organs last mentioned, and also congestion of the lungs, with œdema. Long-continued use of the salt deranges the stomach, causes diarrhoea, emaciation, and a dissolution of the blood, with symptoms resembling those of scurvy. The last-mentioned effect it displays in common with the other alkaline salts, especially those of sodium.

Medical Uses.—This medicine has been used in *typhus fever* and in the *typhoid state* of various febrile affections; that is to say, in which nervous disorder is associated with a tendency to dissolution of the blood. Thus it has been found beneficial in the fever just named, in low forms of *typhoid fever*, *typhoid scarlatina*, *measles*, *erysipelas*, *pneumonia*, etc. There is no reason to suppose that it is, in any sense, a specific for those affections. Like other stimulants, it urges the organs to perform their functions until the poison which is the cause of their debility is eliminated and the tissue-repair advanced, and probably it also quickens their performance of this work. In appropriate doses it has the advantage over alcohol that it leaves no depression behind it, and over turpentine that it is not apt to occasion any local derangements. Like other stimulants, its virtues depend upon the quantity of it administered. In excessive doses it is perturbative and irritant, and if long continued, even in doses which the stomach will tolerate, it impairs nutrition in the manner stated above. Its efficacy in the treatment of bites of *venomous serpents* and *insects* and in *alcoholic intoxication* is, in a great degree, due to its stimulant action; but the extraordinary rapidity with which, when applied locally, it arrests the pain and inflammation of insect-bites, and when taken internally suspends even a high degree of drunkenness, seems to show that it exerts also a more direct antidotal power. In various forms of *bronchitis*, both primary and secondary, it may be employed, the cases in which it is most useful being those which have passed the acute stage, and which tend to become chronic, with dilatation of the bronchia or with consolidation of the vesicular tissue, constituting the so-called broncho-pneumonia. When this form of disease arises, as it often does, as a consequence of measles, ammoniacal medicines ought never to be neglected. The *dyspepsia* of drunkards is said to be favorably modified by this medicine, probably by its combined antacid and stimulant properties, which counteract the acidity and dissolve the tenacious mucus that coats the stomach. The antacid property of the salt has led to its use in cases of excessive secretion of *uric acid*; and in *diabetes* it sometimes diminishes the quantity, as well as the saccharine condition, of the urine. Like other volatile ammoniacal preparations, it is useful in alleviating *headache*, whether dependent upon acidity of the stomach or upon exhaustion of the nervous system. Its stimulant quality renders it useful in *faintness*, *syncope*, *nervous spasms*, etc.; and when mixed with sal ammoniac and scented with an aromatic oil it forms the usual smelling-salts employed to relieve the symptoms just referred to, and also to dissipate congestion of the nostrils in commencing *coryza*. Externally, it is sometimes applied to promote the resolution of *glandular swellings*. It has also been administered internally for the same purpose.

Administration.—Carbonate of ammonium is generally given in a watery solution, and its acrimony is blunted by the use of mucilage, sugar, or liquorice. As a stimulant expectorant its dose is 2 or 3 grains (Gm. 0.10–0.15) or more, repeated every 2 or 3 hours. In low fevers 5 or 10 grains (Gm. 0.30–0.60) should be given every hour or two, until five or six doses are taken. An emetic effect is produced by 30 grains (Gm. 2).

AMMONII CHLORIDUM, U. S., Br.—CHLORIDE OF AMMONIUM.

Ammonium chloratum, P. G.; *Ammonium muriaticum s. hydrochloratum depuratum*, *Chloruretum ammonicum*, *Sal ammoniacum*, *Ammonia hydrochloras s. murias*.—*Purified chloride of ammonium*, *Muriate of ammonia*, *Sal ammoniac*, E.; *Chlorure d'ammonium*, *Sel ammoniac*, *Chlorhydrate d'ammoniaque*, Fr.; *Salmiak*, *Chlorammonium*, *Ammonium chlorid*, *Reiner Salmiak*, G.

Formula NH_4Cl or AmCl . Molecular weight 53.4.

Origin.—The sal ammoniacum of ancient writers was perhaps in all cases rock-salt. In the eighth century Geber prepared sal ammoniac from urine. Subsequently it was manufactured in Egypt from camel's dung and urine, and exported to Europe, where its manufacture was begun in Venice in the seventeenth century, in Great Britain in 1756, and soon after in Germany and France. At present it is obtained from the products of the dry distillation of bones and other animal matters, and of coal. It is frequently met with in the neighborhood of volcanoes, and is a constituent of several mineral springs, such as Hall, Homburg, Wiesbaden, and others.

Preparation.—The so-called coal-gas liquor is a watery liquid condensed in the preparation and purification of illuminating gas from coal, and contains principally carbonate of ammonium, besides some sulphide, cyanide, and empyreumatic products. This is either neutralized by hydrochloric acid or decomposed by chloride of calcium, in both of which cases a solution of ammonium chloride is obtained, which is evaporated and the dry salt afterward sublimed. In order to avoid the expense attending the evaporation of such dilute solutions the gas-liquor is now frequently treated with lime and the generated ammonia gas conducted into a more concentrated acid. If the gas-liquor is neutralized by sulphuric acid, the resulting solution will yield more or less brown-colored crystals of ammonium sulphate, which are mixed with sodium chloride (table-salt), and the mixture is sublimed from iron pots, the vapors being condensed upon the inside of leaden or iron domes. On the application of heat a mutual decomposition of the ammonium sulphate and sodium chloride occurs, resulting in the formation of ammonium chloride, which sublimes, and sodium sulphate, which remains behind; $(\text{NH}_4)_2\text{SO}_4 + 2\text{NaCl}$ yields $2\text{NH}_4\text{Cl} + \text{Na}_2\text{SO}_4$. From the corrosive action of the vapors upon iron the product is always contaminated with chloride of iron.

Instead of using sulphuric acid, the gas-liquor may be digested with powdered gypsum (sulphate of calcium), when ammonium sulphate and insoluble calcium carbonate are produced, the latter retaining a considerable amount of the tarry products. Any liquid containing ammonia or carbonate of ammonium, like the aqueous liquor obtained on the destructive distillation of bones or other animal matter, may be employed in the same manner as coal-gas liquor. The annual importation of sal ammoniac has increased from less than 800,000 pounds previous to 1879 to nearly 1,500,000 pounds in 1882.

When the crude article is refined by carefully resubliming it, ammonium chloride may be obtained sufficiently pure for medicinal use. Commercial sal ammoniac contains, usually, variable quantities of ferrous and ferric chloride, and should be purified by dissolving 2 parts of it in 3 parts of hot water, adding a small quantity of chlorine-water to convert the ferrous into ferric chloride, and afterward ammonia-water in slight excess, then filtering the hot solution from the precipitated ferric hydrate. If the sal ammoniac has been otherwise pure, the filtrate may be evaporated to dryness and the salt granulated by stirring it continually. If, however, it contains other saline impurities besides the iron, it is best to allow the filtrate to cool, stirring it occasionally, and to collect the crystalline powder upon a muslin strainer. The impurities will remain in the mother-liquor.

Properties.—SAL AMMONIAC is imported in casks, and consists of colorless or whitish translucent masses which are of a fibrous crystalline structure, very tough and difficult to powder. It is free from odor and has a cooling and strongly saline taste. Its specific gravity is 1.53, and it is soluble in about 3 parts of cold and in little more than its own weight of boiling water. During the solution of the salt in water a considerable reduction of temperature is observed. When the solution is heated with potassa or lime gaseous ammonia is given off, and when treated with nitrate of silver a curdy white precipitate soluble in ammonia is produced. It is less freely soluble in spirituous liquids, requiring 14 parts of boiling alcohol for solution. The salt is permanent in the air, but its solution on being boiled evolves a little ammonia and acquires an acid reaction. Ammonium chloride evaporates completely without melting at an elevated temperature, and on cooling is condensed again unchanged. Metals which are dissolved by hydrochloric acid are likewise attacked by the hot solution or the vapor of this salt; hence commercial sal ammoniac contains iron, derived from the vessels in which it has been prepared, and its solution turns blue on the addition of ferrocyanide of potassium.

PURIFIED CHLORIDE OF AMMONIUM forms a snow-white granular crystalline powder, the hot solution of which has a faint acid reaction, and does not acquire a bluish-black color by tannin or a blue coloration on the addition of ferrocyanide of potassium. The solubility of pure chloride of ammonium in water has been ascertained by Alluard (1864) for the following temperatures, and a barometric pressure of 718 Mm., at which 100 parts of water will hold in solution,

28.40	32.84	37.28	41.72	46.16	50.60	55.04	59.48	63.92	68.36	72.80	77.24	parts of NH_4Cl
at 0°	10°	20°	30°	40°	50°	60°	70°	80°	90°	100°	110°	C.

Gerardin gives (1865) the following figures, indicating the solubility of chloride of ammonium in 100 parts of alcohol, specific gravity 0.939: At 4° C., 11.2; at 8°, 12.6; at 27°, 19.4; at 38°, 23.6; and at 56° C., 30.1 parts of NH_4Cl .

Tests.—The salt should be completely volatilized from platinum-foil (non-volatile

salts), and should yield a clear solution with 4 parts of water (barium sulphate, lead salts). The solution, in 20 parts of water, should not be affected by sulphydric acid (lead, copper, etc.), diluted sulphuric acid (barium, lead), barium chloride (sulphate), nor, after acidulating with hydrochloric acid, by ferric chloride; a red color produced with the last test would indicate the presence of sulphocyanate, observed by Warington. The U. S. Pharmacopœia requires also absolute freedom from iron, in that the aqueous solution should not be affected by sulphide of ammonium, and a 1 per cent. solution not be rendered blue by potassium ferrocyanide; the readiness with which iron is attacked by the salt and its solution renders this very difficult, and the German Pharmacopœia for this reason permits the presence of a trace of iron, which in a 5 per cent. solution may give a dark-green color, but not a black precipitate, with sulphide of ammonium. Empyreumatic impurities may be detected by moistening 1 Gm. of the salt with nitric acid and drying at the heat of a water-bath, when it should not acquire a brown tint.

Pharmaceutical Uses.—Chloride of ammonium is used for generating ammonia in preparing Aqua ammonia.

AMMONII ET FERRI CHLORIDUM, *s. Ammonium chloratum ferratum*, P. G., *s. Ferrum ammoniatum*; Ammonio-chloride of iron, ammoniated iron, *E.*; Sel ammoniac martial, *Fr.*; Eisensalmiak, *G.*—32 parts of chloride of ammonium are mixed with 9 parts of solution of ferric chloride (*P. G.*), and evaporated with constant stirring to dryness. It is an orange-colored, somewhat deliquescent powder, having a strongly saline and ferruginous taste, and containing 7.25 per cent. of ferric chloride, Fe_2Cl_6 , equal to 12.1 per cent. of crystallized ferric chloride or to 2.5 per cent. of metallic iron. It should yield a clear solution with water, and, being decomposed in the sunlight, should be kept in a dark place.

Physiological Action.—*On Animals*: The general result of experiments in which chloride of ammonium was administered internally by the stomach or by the veins to different animals is that it acts as a depressant of the nervous system, generally inducing tetanic spasms. In some experiments the salt, when injected into the veins, produced temporary paralysis, and not spasm. On the mucous membrane of the alimentary canal it appears to increase the secretion of mucus, while it renders the blood less coagulable, without, however, impairing the constitution of its corpuscles.

On Man: The direct effects of doses of from 5 to 20 grains of this salt, repeated at intervals of several hours, are a sense of oppression, warmth, and uneasiness in the stomach, some fulness of the head, and an increased tendency to urinate. If it is used for many days together in full doses it disturbs the digestion, coats the tongue, and impairs the appetite; it may even occasion gastric pain, vomiting, and diarrhœa. Its prolonged use is said to cause emaciation. The idea which has appeared chiefly to direct its use in medicine is, that it tends to render all the secretions freer and more abundant, while it at the same time lessens the plasticity of the blood; in other words, that its operation is in some respects analogous to that attributed to mercury. Its efficacy in certain cases of neuralgia would appear to point to another mode of operation—those cases, namely, which are apparently pure neuroses, and not painful conditions of the nerves due to pressure upon them by the neurilemma or by the periosteum of bony canals. The action upon the blood referred to above has frequently been illustrated clinically. In one case there were bloody blebs upon the skin and in the mouth, besides hæmaturia and bloody stools (Isham, *Med. News*, xl. 454); in another there was profuse hæmorrhage from the nose, eyes, fauces, and bowels (Lucas, *Med. News*, xl. 587); and in a third instance inhalations of the fumes of the salt seem to have occasioned hæmorrhage from the pharynx (Fuller, *Med. Record*, xix. 474).

Medical Uses.—Chloride of ammonium is sometimes used with a view of promoting the cutaneous efflorescence in *eruptive fevers*; but it is of more value in the cure of obstinate *intermittent fevers*, doubtless through its influence upon the function of nutrition. This value is, however, very uncertain and restricted. In *bronchitis* that has passed its inflammatory stage few medicines are more efficient than this; and in all the chronic forms of the affection occurring in persons of a feeble and relaxed habit of body it is a most valuable remedy when given alone or associated with stimulant expectorants.

Whooping cough is benefited by its use when the sputa are tenacious and excessive. Its wholesome stimulation is manifested in cases of *chronic pharyngitis* accompanied with a flaccid state of the mucous membrane and a glairy secretion. A similar secretion from other mucous membranes, constituting *gleet*, *leucorrhœa*, etc., is often modified favorably by it. The alterative action of the medicine—*i. e.* its slow but steady modification of the nutrition of tissues—is exhibited by its beneficial action in *amenorrhœa* and *dysmenorrhœa*.

when the former depends upon torpor of the uterine system, and the latter upon chronic engorgement of the uterus, with or without catarrh. This action is doubtless exerted by it in those cases of cure which it brings about in the various general disorders that arise from sympathy with the uterine system at the *menopause*. It is also in this manner that it appears to be useful in certain cases of fibrous tumors of the uterus. To a similar mode of action may be referred its utility in chronic glandular enlargements, as in those of the thyroid body (*goitre*), the prostate, the liver, etc. In regard to its utility in *goitre* there can be little doubt. Among many illustrations may be mentioned six cases in which the disease began at puberty, and which were cured after about 3 months of treatment (Stevens, *Med. Record*, xvii. 429). In the case of the liver its administration has been alleged to diminish the tendency to hepatic abscess, but such an assertion must be difficult to substantiate. According to the first and the only physician who has attributed this virtue to the medicine, and whose field of observation was in the East Indies, it should be prescribed in the dose of 20 grains (Gm. 1.30) as soon as pain in the hepatic region gives warning of the danger of suppuration.

The forms of neuralgia in which chloride of ammonium is beneficial are not easily defined. According to certain statements, it is equally useful in rheumatic and idiopathic neuralgias, in those depending upon local congestions, and those associated with anæmia, as well as those of less easy definition which are connected with uterine, gastric, and other functional disorders. We have no doubt that it is chiefly serviceable in neuralgia depending upon cold, in which, indeed, especially in neuralgia of the fifth pair, the intercostal nerves, and the sciatic nerve, it sometimes exerts a very prompt and salutary action. In those cases of diffused neuralgic headache known as hæmicania, and often associated with gastric acidity, this medicine is sometimes beneficial, but less so than the carbonate or the liquid preparations of ammonia. In the muscular aches which are produced by the prolonged and repeated use of the same set of muscles, and which have been styled *myalgia*, this medicine is of service if the tired organs are allowed repose. A somewhat analogous condition obtains in chronic muscular rheumatism, for which also this salt may be advantageously prescribed. Like other ammoniacal preparations, it has been used with alleged benefit for *snake-bites*, but associated with such other active remedies that a judgment of its share in the result is impossible. It has also been recommended in the treatment of hæmorrhage from the stomach, the uterus, and the lungs: but except in the case of the uterus the tendency of bleeding to cease spontaneously is so well known that the influence of a medicine in controlling it demands a clearer demonstration than is offered in this case. This salt is alleged to reduce the proportion of sugar voided in *saccharine diabetes*, but clinical observation does not favor its use in that disease (Guttmann, *Zeitschrift f. klin. Med.*, i. 610; ii. 473; Adamkiewicz, *ibid.*, ii. 195).

The stimulant action of this salt has been employed to stay the progress of *gangrene*, especially of the senile variety. It should be applied in cataplasms or in local baths, according to the situation of the disease. The same action is very usefully resorted to in the treatment of *contusions* and lacerated and contused wounds. In local inflammations the cold produced by it while dissolving may sometimes be taken advantage of. A mixture of 5 parts of it with as many of nitrate of potassium and 16 parts of water will lower the thermometer from 50° to 10° F. Such a mixture, contained in a bladder, has been used to promote the reduction of *hernial tumors* and in various cutting operations of minor surgery. Chloride of ammonium forms a useful ingredient of *eroline* powders, *gargles*, *dentifrices* for whitening the teeth, *cosmetic* preparations for removing the pimples of *acne* from the face, plasters for the treatment of enlarged *bursæ* and *joints*, and atomized solutions for the cure of *pharyngeal* and *laryngeal* affections requiring direct stimulation. Among the last are nervous *aphonia* and *chronic bronchitis*.

Administration.—The dose of chloride of ammonium varies from 5 to 30 grains (Gm. 0.30–2.00), but a larger dose than 10 grains is seldom necessary. It is best administered in solution, and its taste may be disguised by the addition of extract of liquorice or the syrup of liquorice-root. In bronchial diseases its virtues are increased by this association. In neuralgia it may be necessary to repeat hourly the dose of 5 or 10 grains (Gm. 0.30–0.60) for 3 or 4 consecutive hours. In affections of the air-passages it may be given by the stomach, and also by the inhalation of an atomized saturated solution of the salt in water. The *ammonio-chloride of iron* is credited by some German therapeutists with special virtues in scrofula, anæmia, and other states involving general debility. There is no sufficient ground for this opinion, and the taste of the preparation is so disagreeable that the use of it may well be dispensed with. Its dose is said to be from 3 to 10 grains. It may be given in a solution of extract of liquorice.

AMMONII IODIDUM, U. S.—IODIDE OF AMMONIUM.

Ammonium iodatum, Ioduretum ammonicum.—*Iodure d'ammonium*, Fr.; *Jodammonium, Ammoniam jodid*, G.

Formula NH_4I or AmI . Molecular weight 144.6.

Preparation.—This salt is most advantageously prepared by the process recommended by Jacobsen in 1863, and which, with some modifications, was adopted by the U. S. Pharmacopœia of 1870. After correcting the errors in the latter this process is as follows: Mix potassium iodide in coarse powder $2\frac{1}{2}$ troyounces and ammonium sulphate in coarse powder 1 troyounce; add to the mixture 2 fluidounces of boiling water; stir well, allow to cool slowly, add 2 fluidounces of alcohol, and place the mixture in a bath of iced water, stirring occasionally; throw the mixture into a glass funnel stopped with moistened cotton, collect the clear liquid, and wash the crystalline salt with diluted alcohol; lastly, evaporate the filtrate rapidly to dryness, stirring constantly. Contact with iron or other metals is to be avoided.

1 molecule of ammonium sulphate (132 parts) and 2 molecules of potassium iodide (331.2 parts) decompose each other when mixed in solution, with the formation of iodide of ammonium and sulphate of potassium; $2\text{KI} + (\text{NH}_4)_2\text{SO}_4$ forms $2\text{NH}_4\text{I} + \text{K}_2\text{SO}_4$. The latter salt, being insoluble in alcohol, will separate from the solution as a crystalline powder on adding alcohol and cooling the mixture, after which the filtrate may be evaporated to dryness, yielding rather more than $2\frac{1}{8}$ troyounces of the iodide. The minute quantity of sulphate of potassium contained in it does not interfere with its medical properties. If a still purer salt is desired, the product may be dissolved in alcohol, filtered from the insoluble potassium sulphate, and evaporated as before.

Other processes have been proposed, of which the following may be mentioned: Hydriodic acid is neutralized with ammonia or ammonium carbonate. Ferrous iodide is decomposed by ammonium carbonate, and the filtrate evaporated (Ch. Ellis, 1835). Potassium iodide and ammonium bitartrate are made to react upon each other in hot solutions; on cooling, potassium bitartrate crystallizes, and the evaporated filtrate, still containing a little of this salt, is treated with 70 per cent. alcohol, which dissolves only the ammonium iodide (W. H. Pile, 1862). Iodine is treated with sulphide of ammonium until the brown color has completely disappeared, when the solution is boiled, filtered from the liberated sulphur, and evaporated (Spencer, 1852).

When iodine is added to ammonia-water, iodide of ammonium is produced, but at the same time the extremely explosive compound iodide of nitrogen results. Mixtures of the two substances named should therefore be made with great caution.

"Iodide of ammonium should be preserved in small, well-stopped vials, protected from light. When deeply colored it should not be dispensed, but it may be deprived of all but traces of free iodine by washing with stronger ether and rapidly drying."—*U. S.*

Properties.—Iodide of ammonium is in white granular crystals, and on the slow evaporation of its solution, which should be kept slightly alkaline by ammonia, is obtained in colorless and inodorous cubes having the specific gravity 2.498. If the air is excluded the salt sublimes undecomposed; in contact with the atmosphere it acquires a yellowish-brown color and a slight odor of iodine. The salt is very deliquescent, and dissolves freely in water and alcohol, requiring 1 part of water and 9 parts of alcohol at 15°C . (59°F .), .5 part of boiling water, and 3.7 parts of boiling alcohol for solution (*U. S.*); the solutions have a slight acid reaction and become yellow on exposure. Iodine is liberated on the addition of nitric acid and ammonia by potassa or lime. On the addition of a little chlorine-water to the aqueous solution of the salt, iodine is set free, which will dissolve in chloroform or in disulphide of carbon with a violet color, and will impart a blue color to mucilage of starch; excess of chlorine will prevent these color-reactions through the formation of colorless compounds.

Tests.—The purity of the salt is recognized by its complete volatility, and by its solution yielding not any, or only a slight, turbidity with barium chloride (sulphate). Bromide and chloride of ammonium are recognized by precipitating the solution with silver nitrate and adding ammonia in excess, in which silver iodide is very sparingly soluble, so that the ammoniacal liquid will yield merely a slight turbidity on the addition of nitric acid. If a precipitate occurs, this is agitated with chlorine-water gradually added in the presence of chloroform, which will be colored red if bromine be present; if the chloroform is not colored, the impurity is a chloride. The limits of impurities are thus ascertained: "On adding to 1 Gm. of the salt, dissolved in 20 Cem. of water (with a few drops of dilute hydrochloric acid), 5 or 6 drops of test solution of nitrate of barium,

no immediate cloudiness or precipitate should make its appearance (limit of sulphate). If 1 Gm. of the salt be dissolved in 10 Gm. of water of ammonia, then shaken with a solution of 1.3 Gm. of nitrate of silver in 20 Gm. of water, and the filtrate be super-saturated with 8 Gm. of nitric acid, no cloudiness should make its appearance within 10 minutes (absence of more than about 0.5 per cent. of chloride and bromide). A 1 per cent. aqueous solution should not be colored blue by test solution of ferrocyanide of potassium (absence of iron), nor, after being mixed with gelatinized starch, should it assume a deep-blue color (limit of free iodine).—*U. S.* The solution of 10 grains of iodide of ammonium, treated with sufficient nitrate of silver, yields a precipitate of iodide of silver, which, after washing and drying, weighs 162 grains (or 1.62 Gm. from 1 Gm. AmI).

Physiological Action and Medical Uses.—This salt has the general properties of the alkaline iodides, but is more active as well as more transient in its effects. It is said that 8 grains (Gm. 0.50) (Böcker), and even 20 grains (Gm. 1.30) (Gamberini), may be taken at a dose without other effect than some warmth and irritation of the throat and stomach. It was first used in an ointment for *psoriasis, tinea capitis*, and other scaly affections of the skin, particularly those due to a syphilitic infection, and it was afterward administered internally for the same class of affections with success. As a topical application in ointments and poultices it reduces *enlarged glands*, and, being more irritating than iodide of potassium, is probably superior to the latter salt for this purpose, but it is inferior to the iodide of lead. A solution of 30 or 40 grains (Gm. 2.00–2.60) of the salt in a fluidounce of glycerin has been used with the same object, and also as an application to enlarged and indurated *tonsils*. It is sometimes added to volatile, camphorated, and other liniments used for the relief of *rheumatic* and other local pains. The *dose* of this iodide is from 1 to 5 grains (Gm. 0.06–0.30) and upward. It should be dissolved in water with syrup, and dispensed in bottles of blue glass to prevent its decomposition by the light. An ointment containing from 30 to 60 grains (Gm. 2–4) of the salt in an ounce of lard should be freshly prepared when required.

AMMONII NITRAS, *U. S.*—NITRATE OF AMMONIUM.

Ammonie nitras, Br. Add.; *Ammonium nitricum*, *Nitrum flammans*.—*Nitrate of ammonia*, E.; *Azotate d'ammoniaque*, *Nitre inflammable*, *Nitre ammoniacal*, *Sel ammoniacal nitreux*, Fr.; *Salpetersaures Ammon* (*Ammonium*, *Ammoniak*). *Ammoniumnitrat*, G. Formula NH_4NO_3 or AmNO_3 . Molecular weight 80.

Preparation.—Ammonium nitrate exists in small quantity in the atmosphere and in rain-water, particularly after thunder-storms; likewise in the water of several springs. On dissolving iron in nitric acid the same salt is formed through the action of nascent hydrogen upon a portion of the acid; many other metals have the same effect.

For preparing ammonium nitrate, nitric acid is neutralized with ammonia or ammonium carbonate, or, in place of the latter, the pulverulent bicarbonate which accumulates in the shops may be advantageously employed: the solution is concentrated by evaporation and crystallized, or until it congeals on cooling. On the large scale it is manufactured from ammonium sulphate and potassium nitrate, the mixed solutions of which yield, first, crystals of the less freely soluble potassium sulphate, afterward crystals of ammonium nitrate, which require to be purified by recrystallization.

Properties.—Ammonium nitrate crystallizes in colorless hexagonal prisms, or on the rapid refrigeration of the concentrated solution in long, flexible, thread-like needles; after fusion it forms colorless crystalline, inodorous masses. It has the specific gravity 1.70, and possesses a sharp bitter taste. It deliquesces in contact with moist air, and dissolves at ordinary temperatures in about half its weight, and in much less of boiling water. It dissolves in 2.20 parts of alcohol, specific gravity 0.880, at 25° C. (77° F.) (Pohl); in 1.1 parts of boiling alcohol (Wenzel); in 20 parts of alcohol at 15° C. (59° F.), and in 3 parts of boiling alcohol (*U. S. P.*). The solutions on exposure or on heating lose ammonia and acquire an acid reaction. The salt deliquesces in ammonia gas, forming a solution in liquefied ammonia, as observed by Divers (1872); at 23° C. (73.4° F.) and the pressure of the atmosphere the liquid consists of 4 parts, and at 0° C. (32° F.) of 2 parts, by weight, of the nitrate to 1 part of ammonia; but under greater pressure or at lower temperatures much more ammonia can be condensed by the nitrate. Like an aqueous solution, the liquid boils when heated, and may crystallize on cooling or become supersaturated with the salt without crystallizing; at 80° C. (176° F.) the whole of the ammonia is expelled. Ammonium nitrate softens on the application of heat, and fuses

at 108° C. (226.4° F.) (Pleischl), at 152° C. (305.6° F.) (Berthelot, 1872), at 165° to 166° C. (329°–330.8° F.) (Pickering, 1878), the difference in these observations being doubtless due to the presence of moisture and other impurities. The same causes affect also the temperature at which the salt is decomposed, and which has been determined at 185° C. (365° F.) by Pickering, at 190°–200° C. (374°–392° F.) by Legrand, at 210° C. (410° F.) by Berthelot, and at near 240° C. (464° F.) by Pleischl. A portion of the salt is volatilized unaltered. When rapidly heated it is decomposed into water, nitrous acid, and nitrogen, or into nitrous and nitric oxides, nitrite of ammonium, and ammonia; but if gradually heated it is decomposed into water and nitrous oxide, or *laughing gas*, N_2O . This decomposition is effected according to the following equation: $NH_4NO_3 = N_2O + 2H_2O$. It is evident from this that in the preparation of nitrous oxide gas to be used for inhalation the heat should be carefully regulated and the gas pass through solutions of potassa (or lime-water) and ferrous sulphate, whereby all the gaseous impurities, except the nitrogen which may be present, are completely removed, even if chlorine should have been evolved in consequence of the presence of ammonium chloride in the nitrate.

The salt detonates when thrown upon red-hot charcoal or when mixed with powdered charcoal and heated to 170° C. (338° F.). When mixed with sulphuric acid, nitric acid vapors are given off, and potassa or lime evolves ammonia when heated with the aqueous solution.

Tests.—The salt should be completely volatilized without charring when heated upon platinum-foil, and its aqueous solution should not be precipitated either by silver nitrate or barium chloride (absence of chloride and sulphate).

Medical Action.—This substance is seldom used in medicine. It is generally regarded as having properties analogous to those of potassium nitrate. It is made official chiefly as the source from which nitrous oxide gas is derived by means of heat.

AMMONII PHOSPHAS, U. S.—PHOSPHATE OF AMMONIUM.

Ammoniae phosphas, Br.; *Ammonium phosphoricum*, *Phosphus ammonicus*.—*Phosphate of ammonia*, *Diammonium orthophosphate*, E.; *Phosphate d'ammoniaque*, Fr.; *Ammonium-phosphat*, *Phosphorsäures Ammon* (*Ammonium*, *Ammoniak*), G.

Formula $(NH_4)_2HPO_4$. Molecular weight 132.

Preparation.—Take of Diluted Phosphoric Acid 20 fluidounces; Strong Solution of Ammonia a sufficiency. Add the ammonia to the phosphoric acid until the solution is slightly alkaline, then evaporate the liquid, adding ammonia from time to time so as to keep it in slight excess, and when the crystals are formed on the cooling of the solution dry them quickly on filtering-paper placed on a porous tile, and preserve them in a stoppered bottle.—*Br.*

This process yields the salt by the direct union of tribasic phosphoric acid and ammonia. Since the salt has a distinct alkaline reaction and heat expels a portion of the ammonia, it becomes necessary to add ammonia-water from time to time, and particularly when the solution is set aside to crystallize, in order to preserve the alkaline reaction, otherwise this so-called neutral salt will be mixed in variable proportions with the acid phosphate, having the composition $NH_4H_2PO_4$. The official salt may also be obtained from bones calcined to whiteness by the process for PHOSPHATE OF SODIUM (which see), if the sodium carbonate there directed is replaced by ammonium carbonate, and the resulting liquid, after suitable concentration, is rendered alkaline by the addition of some ammonia. If necessary, the salt obtained is to be purified by recrystallization from distilled water, with the addition of a little ammonia, until the crystals are free from sulphate. If the crystallizing liquid should have been rendered strongly alkaline by ammonia, the salt would consist of or contain triammonium (the so-called basic) orthophosphate of the formula $(NH_4)_3PO_4$.

Properties.—The official phosphate of ammonium crystallizes in transparent colorless, monoclinic prisms having the specific gravity 1.678 (Buignet, 1861). It has a cooling and sharply saline taste, effloresces superficially in a damp atmosphere through loss of ammonia, is insoluble in alcohol, but dissolves in 4 parts of water at 15° C. (59° F.) and in .5 parts of boiling water, yielding a solution which is at first slightly alkaline, but on exposure becomes neutral through loss of ammonia, and by continued boiling loses one-half of it. The solution yields a yellow precipitate with nitrate of silver, soluble in nitric acid and ammonia, and evolves ammonia when heated with potassa. The salt, when heated, fuses and is gradually decomposed into metaphosphoric acid, ammonia, and water, and at a bright red heat is finally completely volatilized.

Tests.—20 grains of the salt, dissolved in water and precipitated by ammonio-sulphate of magnesium (test mixture of magnesium, *U. S.*), yield a crystalline precipitate which, when well washed with diluted ammonia-water, dried, and ignited, weighs 16.8 grains, *Br.* (1.68 Gm. from 2 Gm. of the salt, *U. S.*). The solution should not be affected by sulphide of ammonium, or, after being acidulated with nitric acid, by hydrosulphuric acid (absence of metals), and should yield no precipitate with barium chloride (sulphate) or silver nitrate (chloride). 10 grains of the salt, gradually heated upon platinum-foil to redness, should leave a residue weighing 6.1 grains.

Physiological Action and Medical Uses.—This medicine was originally proposed as a remedy for *gout*, upon the theoretical ground that it would produce, with the uric acid in the system, more soluble salts than those of soda and lime, which form the bases of gouty concretions. By a singular perversion of logic the same condition was assumed to exist in *rheumatism*, which is a totally different disease, essentially as well as clinically. It was indeed pointed out that, even from a chemical point of view, the administration of the medicine would be apt to favor the formation of ammoniaco-magnesian calculi. However, it was alleged that during the use of the medicine uric acid rapidly disappeared from the urine, and that the pains and other local phenomena in the joints during acute gout and rheumatism subsided, just as they do in the latter disease under the use of the carbonates of the alkalis. No general concurrence in the results of observation has confirmed the special if not specific advantages ascribed to this medicine at its introduction, and which are neither greater than those of the other alkalis nor different from them. Like them, phosphate of ammonium has been found very serviceable in many cases of *diabetes* by maintaining a highly alkaline condition of the blood, and thereby diminishing the amount of sugar eliminated with the urine. The *dose* is from 10 to 20 grains (Gm. 0.60–1.30) three times a day, dissolved in water or in some mild liquid, such as barley- or rice-water.

AMMONII SULPHAS, *U. S.*—SULPHATE OF AMMONIUM.

Ammonium sulphuricum, Sulphas ammonicus, Sal ammonium secretum Glauberi.—*Sulfate d'ammoniaque, Sel secret de Glauber, Fr.; Schwefelsaures Ammon (Ammonium, Ammoniak), Ammoniumsulfat, G.*

Formula $(\text{NH}_4)_2\text{SO}_4$ or Am_2SO_4 . Molecular weight 132.

Origin.—Ammonium sulphate was observed by Libavius (1595), and first prepared from oil of vitriol and volatile alkali by Glauber (1667), after which time it was much employed as a purgative. The salt is a constituent of a few minerals, and is sometimes found in the neighborhood of volcanoes.

Preparation.—Sulphate of ammonium is largely obtained from coal-gas liquor (see AMMONII CHLORIDUM) by neutralizing it with sulphuric acid or by digesting it with sulphate of calcium. A convenient process is to percolate the gas-liquor through powdered gypsum, whereby carbonate of calcium is left in the percolator and sulphate of ammonium is found in the filtrate: $\text{CaSO}_4 + (\text{NH}_4)_2\text{CO}_3$ yields $\text{CaCO}_3 + (\text{NH}_4)_2\text{SO}_4$. The solution is evaporated; the resulting crystals are gradually heated to about 240°C . (464°F .) to expel tarry compounds, and then recrystallized from water. Nearly all that is consumed in the United States is manufactured here.

Properties.—It forms colorless rhombic prisms isomorphous with sulphate of potassium, free from odor, and of a sharp saline and bitterish taste. It has the specific gravity 1.76, fuses at 140°C . (284°F .), and is decomposed at a heat exceeding 260°C . (500°F .), yielding ammonia, water, nitrogen, and a sublimate of ammonium sulphite with a little ammonium sulphate. 100 parts of water dissolve, according to Allard (1864),

71.00	73.65	76.30	78.95	81.60	84.25	86.90	89.55	92.20	94.85	97.50	parts of Am_2SO_4
at 0°	10°	20°	30°	40°	50°	60°	70°	80°	90°	100°C .	

The solution in cold water has a neutral reaction to test-paper, but on exposure or on boiling evolves a little ammonia and acquires a faint acid reaction (Deblits, 1872). It is insoluble in absolute alcohol, requires for solution about 500 parts of alcohol (spec. grav. .88), but dissolves more freely in weaker alcohol. Its solution evolves ammonia when heated with potassa or lime, and chloride of barium produces in it a white precipitate insoluble in diluted nitric acid.

Tests.—When gradually heated to redness the salt should not be blackened, and should finally leave no residue upon platinum-foil. Metals, chlorides, and other impurities are detected in the same manner as in other ammonium salts; the allowable limits are

thus determined: "A 1 per cent. solution of the salt should not be blackened by test solution of sulphide of ammonium (lead and iron), nor, when acidulated with nitric acid, should it be rendered more than opalescent by test solution of nitrate of silver (limit of chloride)." — *U. S.*

Uses.—This salt is extensively used in the manufacture of ammonia-water, chloride of ammonium, and ammonia alum; also for Ferri et ammonii sulphas.

Medical Action.—This salt is not used as a medicine.

AMMONII VALERIANAS, *U. S.*—VALERIANATE OF AMMONIUM.

Valerianus ammonicus.—*Valériante d'ammoniaque*, Fr.; *Ammoniumvalerianat*, *Baldriansaures Ammonium*, G.

Formula $\text{NH}_4\text{C}_5\text{H}_9\text{O}_2$. Molecular weight 119.

Preparation.—The practical details of the process recognized by the U. S. Pharmacopœia of 1870 were published by B. J. Crew (1860), and are based upon Chevreul's observations that concentrated valerianic acid, placed in an atmosphere of ammonia, yields this salt in crystals. A convenient quantity of valerianic acid (spec. grav. .935) is placed in a tall, narrow glass vessel and saturated with dry ammonia gas, which is generated from a mixture of equal weights of ammonium chloride and slaked lime, the gas being dried by passing it through a bottle filled with pieces of burned lime. On the combination of the dry ammonia gas with the acid much heat is produced, and after neutralization has been attained the salt crystallizes readily on cooling; after several hours it is broken into pieces, drained, if necessary, in a glass funnel, dried on bibulous paper, and preserved in a well-stopped bottle. Valerianic acid, which is weaker than the above and of higher specific gravity, yields few or no crystals by this process.

Properties.—Valerianate of ammonium, thus prepared, forms colorless or white quadrangular plates having the odor of valerianic acid and possessing a sharp and sweet taste. It effloresces when placed in a dry atmosphere, and deliquesces in moist air. On the application of heat it fuses, giving off ammoniacal and acid vapors, and is finally dissipated without leaving any residue. It dissolves freely in water and alcohol, the solutions being neutral, and on evaporation acquiring an acid reaction from the loss of ammonia. Alkalies decompose it with the evolution of ammonia, and the stronger acids with the separation of oily valerianic acid, floating upon the aqueous solution. Should the salt have an acid reaction, its solution, when dispensed, should be neutralized by the careful addition of ammonia, whereby the disagreeable odor and taste of valerianic acid are masked to a considerable extent.

Tests.—Heated to redness upon platinum-foil, the salt should leave no residue (potassium, etc. salts). Its aqueous solution, after having been acidulated with nitric acid, should not be precipitated by chloride of barium (sulphate) or nitrate of silver (chloride), or, after having been rendered alkaline by ammonia, by sulphate of magnesium (phosphate). When the aqueous solution is treated with an excess of sulphuric acid, and the clear watery liquid is nearly neutralized with ammonia, a deep-red coloration should not be produced on the addition of ferric sulphate or chloride (absence of acetate).

Medical Uses.—Of the physiological action of this salt we have no knowledge; like several other medicines, including valerian itself, its influence is exhibited chiefly in certain morbid conditions due to exhaustion of the nervous system. It was first employed successfully for the relief of *neuralgia* of this description, and it continues to be used as a convenient palliative for that affection, for *nervous headache*, *nervousness*, *insomnia*, *hysterical disorders*, *palpitation of the heart*, etc. It would be a waste of time to prescribe it in cases of epilepsy, chorea, and fully-formed hysterical convulsions. *Dose*, from 2 to 10 grains (Gm. 0.10–0.60), dissolved in water, with the addition of a flavoring tincture, which also preserves the salt from decomposition.

AMPELOPSIS.—VIRGINIA CREEPER.

American ivy, E.; *Vigne vierge*, Fr.; *Wilder Wein*, *Amerikanischer Epheu*, G.

The young branches and bark of Ampelopsis (*Cissus*, *Persoon*, *Vitis*, *Michx.*) *quinquefolia*, *Michaux*, s. *Vitis* (*Cissus*, *Barton*) *hederacea*, *Willdenow*.

Nat. Ord.—Vitaceæ.

Description.—The Virginia creeper is a woody vine, climbing extensively by adventitious roots and by tendrils; it has digitate leaves composed of five oblong lanceolate somewhat dentate leaflets, and cymose clusters of greenish flowers with five unconnected

deciduous petals, and produces two-celled and two- or four-seeded acidulous blue-black berries of the size of a pea. The young branches and bark are employed, and collected in autumn. The plant is indigenous to North America, and is often cultivated here and in Europe as a covering for walls.

Constituents.—The leaves were analyzed by Wittstein (1845) and by Gorup-Besanez (1872 and 1874). Collected in June, they contain albumen, sugar, pyrocatechin, free tartaric acid, potassium bitartrate, and calcium tartrate; when collected in September no potassium bitartrate or free tartaric acid was found, and in addition to the other constituents pectin and glycolate of calcium were obtained. The berries contained the same principles except glycolic acid.

The root of *Amp. Botrya*, *De Candolle*, of South-eastern Africa, is reputed to possess diuretic properties.

Medical Action.—There appears to be nothing recently added to the scanty statements long ago made regarding this plant. A decoction or infusion of the bark was said to be useful in dropsy, and “to act rather by stimulating absorption than as a diuretic.” The therapeutics of this statement is probably crude as its physiology.

AMYGDALA.—ALMOND.

Amandes, Fr.; *Mandeln*, G.

The seed of the almond tree, *Amygdalus communis*, *Linné*, s. *Prunus Amygdalus*, *Stokes*. Bentley and Trimen, *Med. Plants*, 99.

Nat. Ord.—Rosaceæ, Amygdaleæ.

Official Varieties.—1. AMYGDALA AMARA, U. S., Br.; *Amygdalæ amara*, P. G.; *Semen Amygdali amarum*.—*Bitter Almond*, E.; *Amandes amères*, Fr.; *Bittere Mandeln*, G. The seed of *Amygdalus communis*, *Linné*, var. *amara*, *De Candolle*.

2. AMYGDALA DULCIS, U. S., Br.; *Amygdalæ dulces*, P. G.; *Semen amygdali dulce*.—*Sweet Almond*, E.; *Amandes douces*, Fr.; *Süsse Mandeln*, G.

The seed of *Amygdalus communis*, *Linné*, var. *dulcis*, *De Candolle*.

Origin.—The almond tree is probably indigenous to Western Asia, but at an early period was introduced into Northern Africa and Southern Europe, where by long cultivation numerous varieties have been produced, differing mainly in the size and shape of the fruit and in the hardness of the shell (endocarp). It has also been introduced in the warmer parts of the United States and in other countries of the warmer temperate and subtropical regions; in California, according to M. J. Murphy, about 100 trees are planted to the acre, and begin to yield fruit when three years old of an average value of \$50, increasing to \$2000 in the eighth year. The tree attains a height of 15 to 20 feet (5 to 6 M.), and with its bright green foliage and large rose-colored or white flowers presents a handsome appearance. The fruit is a short-stalked, ovate drupe about 1½ inches (38 Mm.) long, 1 inch (25 Mm.) broad, somewhat flattened, with a groove on one side, covered with a greenish leathery sarcocarp, which is whitish velvety hairy, splits at maturity, and falls away from the putamen; this constitutes the *commercial* almond, which, at least in California, is bleached and rendered of uniform appearance by exposure to the vapors of burning sulphur, whereby insects present are also destroyed. The putamen, deprived of its hard shell, the thick or papery endocarp, furnishes the *official* almond. The bitter and sweet almond trees do not differ from each other botanically, and even the fruits and seeds of the two varieties resemble each other closely.

Description.—The sweet and bitter almonds cannot be distinguished from each other except by one of their constituents and their taste. Bitter almonds are usually thinner, broader, and shorter than the larger variety of the sweet almond, which is ordered by the British Pharmacopœia, and which is known in our commerce by the name of *Jordan almonds*. They are cultivated in Spain; the best are exported from Malaga, and are a hard-shelled variety, but are frequently seen in commerce deprived of the shell. The soft-shelled sweet almonds (variety *fragilis*, *De Candolle*) are cultivated largely in the Balearic Isles (Majorca), and are exported from Valencia and the Mediterranean ports of France and Italy. The cheapest variety are the Barbary almonds, which are small and unsightly in appearance.

Jordan or Malaga almonds are about an inch (25 Mm.) in length and $\frac{3}{8}$ inch (15 Mm.) broad, flattened, and ovate-lanceolate in shape. The testa is of a cinnamon-brown color and scurfy upon its surface from detached cells; it adheres to the whitish tegmen, and the two integuments are easily detached from the white embryo or kernel (blanched) after the seed has been soaked in lukewarm water for a short time. The hilum is just

below the pointed end and upon one edge of the almond, the raphe running along this edge to the broad end, where it forms the broad chalaza, and divides into about sixteen branches, which pass in plainly visible lines toward the pointed end. The embryo consists of two plano-convex white and oily cotyledons of the size and shape of the seed, between which, near the pointed end, the flat plumule is placed, with the short thick radicle somewhat projecting. The tissue of the embryo is made up, besides a small number of delicate fibro-vascular bundles, of thin-walled, irregularly angular parenchyma-cells filled with fixed oil and granules of different size. Almonds are inodorous, and have a sweetish bland, nutty taste, that of the bitter variety being decidedly bitter and aromatic.

The embryo of both varieties of almonds yields, on being triturated with water, a milk-white emulsion, which is either inodorous and sweet or aromatic and bitter, according to the variety used.

Constituents.—Both varieties of almonds have qualitatively the same composition, except that amygdalin is found in bitter but not in sweet almonds. The fixed oil (see *OLEUM AMYGDALÆ EXPRESSUM*) is present to the amount of 45 to 56 per cent., the sweet almonds yielding usually from 5 to 10 per cent. more than the bitter. About 3 per cent. of mucilaginous matter, 6 per cent. of sugar, and 24 to 30 per cent. of protein compounds, besides water and cellular tissue, are found in almonds. On keeping almonds for several days in absolute alcohol they become covered with minute crystals, which Portes (1876) recognized as asparagin. Ludwig and Scheitz (1872) found in unblanched almonds tannin, giving a green reaction with ferric salt, green resin, and a bitterish acrid yellow substance, which is possibly a glucoside; the three compounds seem to be contained only in the integuments; the last two yield with caustic soda a cherry-red color, which, with more alkali, turns dingy-green. The sugar of almonds is mostly glucose, but Pelouze obtained (1855) also cane-sugar. The two protein compounds are, according to Ritthausen (1872), modifications of vegetable casein. Both are soluble in cold water; one, the *conglutin* of Ritthausen and *amandin* of Comaille (1866), being precipitated by acetic acid, while the second compound, known as *emulsin* or *synaptase*, may afterward be precipitated by alcohol, together with some inorganic salts. Both protein compounds act as emulsifying agents in suspending the fixed oil when the almonds are triturated with water; but it appears to be the emulsin only which is capable of decomposing the amygdalin of bitter almonds into hydrocyanic acid and benzaldehyd. (See *OLEUM AMYGDALÆ AMARÆ*.)

Amygdalin, $C_{20}H_{27}NO_{11}$, was discovered by Robiquet and Boutron-Charlard (1830) by exhausting bitter almonds, deprived of their fixed oil, by alcohol; they also observed that the residue would not yield oil of bitter almonds in contact with water. Liebig and Wöhler found (1837) that amygdalin, on being decomposed by emulsin, yields, besides oil of bitter almonds and hydrocyanic acid, also grape-sugar; it was the first glucoside discovered. Amygdalin is obtained from bitter almonds to the amount of from 1 to 3 per cent., and is also contained in the bark, leaves, flowers, and seeds of many trees and shrubs of the sub-orders Amygdaleæ and Pomææ; according to Henschen (1872), also in minute quantity in sweet almonds, and, according to Ritthausen and Kreussler (1870), in the vetch. It occurs sometimes in an amorphous condition, but as obtained by alcohol from bitter almonds, peach-kernels, etc. it crystallizes with $2H_2O$, the water being expelled at $120^{\circ} C.$ ($248^{\circ} F.$). It is soluble in about 15 parts of water, has no odor, but a bitter taste, and is not poisonous unless decomposed by emulsin. Henschen found that this decomposition is also effected by rye-, wheat-, and pea-flour, but it is uncertain whether by the agency of emulsin or another proteid. 17 grains of anhydrous amygdalin yield 1 grain of hydrocyanic acid. On boiling amygdalin with an alkali it is decomposed into ammonia and *amygdalic acid*, $C_{20}H_{25}O_{13}$, the latter, on being boiled with dilute acids, yielding glucose and *mandelic* or *phenylglycolic acid*, $C_8H_8O_3$ or $C_6H_5.CHOH.CO_2H$.

Almonds yield from 3 to 5 per cent. of ash, consisting mainly of potassium, calcium, and magnesium phosphates.

FIG. 12.

Almond: section through seed-coats and portion of cotyledon. Magnified 190 diameters.

FIG. 13.

Almond.

Preservation.—Bitter almonds should be kept unbroken and in a dry atmosphere, to prevent the decomposition of amygdalin and of the fixed oil. Almonds the embryo of which has become discolored or acquired a rancid odor and taste, or has been partly converted into gum (bassorin), as described by Vulpius (1878), are unfit for medicinal purposes.

Pharmaceutical Uses.—Both varieties are employed for obtaining Oleum amygdalæ and in preparing Syrupus amygdalæ. Sweet almonds enter into the composition of Mistura amygdalæ, Syrupus amygdalæ, U. S. and Pulv. amygdalæ comp., Br.

Physiological Action and Medical Uses.—Sweet almonds are used to prepare an emulsion, and also an oil, which are treated of elsewhere. With them a kind of bread is made which is a tolerable substitute for wheaten bread in the treatment of *diabetes*. Bitter almonds and their essential oil are excessively poisonous in large doses, owing to the quantity of hydrocyanic acid developed in the former by admixture with water and by the presence of the same acid in the latter. A drachm of bitter-almond pulp will kill a pigeon or a kitten. The symptoms produced in man by an overdose of this substance are great debility and depression, cyanosis, collapse, convulsions or muscular rigidity (see ACID HYDROCYANICUM), and, if the dose is fatal, insensibility occurs suddenly, with frothing at the nose and mouth, and after death the eyes remain fixed and glistening. Non-poisonous doses are apt to produce an eruption of urticaria—an effect which sometimes follows the ingestion of sweet almonds.

In preparing the almond for food in cases of *diabetes*, it is first blanched, then subjected to a strong pressure to expel a portion of the oil, treated with boiling water slightly acidulated with tartaric acid to remove the sugar, and then ground to a fine powder, which can be made into cakes and puddings with eggs and cream. These products have a pleasant taste and are said to be quite digestible.

The proper treatment in poisoning by bitter almonds consists in evacuating the stomach by means of the finger in the throat or the administration of a mechanical emetic, such as sulphate of zinc. If the patient is unable to swallow, the stomach-pump should be used. If respiration fails the galvanic battery should be resorted to without delay. Reaction may be promoted by small but repeated doses of brandy or whiskey and the application of ammonia to the nostrils.

AMYL NITRIS, U. S., Br. Add.—NITRITE OF AMYL.

Amylium nitrosum, P. G.; *Amylæther nitrosus*.—*Amylo-nitrous ether*, E.; *Azotite d'amyl*, *Ether amylozoteux*, Fr.; *Amylnitrit*, G.

Formula $C_5H_{11}NO_2$. Molecular weight 117.

Preparation.—Purified amylie alcohol is introduced into a capacious glass retort with about an equal bulk of nitric acid; a gradually-increasing heat is applied until the mixture approaches boiling, when the reaction will proceed spontaneously. The distillate is collected until the temperature in the retort rises above 100° C. (212° F.), the portion distilling at a higher temperature containing much nitrate of amyl and ethylamylie ether. The distillate obtained below 100° is agitated with water and an alkali (potassa, lime, or their carbonates) to remove hydrocyanic, nitric, and nitrous acids; and the oily layer, which separates, is rectified from a clean retort by a gradually-increased heat, amylie aldehyd coming over in the first portion; that distilling between 95° and 100° C. is collected separately. (See *Amer. Jour. of Pharmacy*, 1871, p. 147.) If not carefully rectified it requires to be purified by fractional distillation.

This is Balard's process (1844), with some modifications. A. B. Tanner (1871) prepares it more advantageously by mixing, in a glass retort containing some copper wire, 10 measures of pure amylie alcohol with 1 measure of sulphuric acid and 1 measure of nitric acid previously diluted with an equal bulk of water. On the application of a gentle heat the reaction will commence at about 18.3° C. (65° F.), and gradually rise to about 36.6° C. (98° F.). The contents of the retort are cooled, more nitric acid is added, and the distillation continued as before as long as any ether is obtained. This is then washed and rectified as before. The reaction between amylie alcohol and the undiluted acids is extremely violent.

Properties.—Nitrite of amyl is an ethereal liquid of a yellowish color, a neutral reaction, a peculiar not disagreeable fruit-like odor, and a pungent aromatic taste. The U. S. Pharmacopœia requires its spec. grav. to be .872 to .874, while Rieckher has determined it to be .877 and Bunge .905 at 14.5° C. (58° F.). Amyl nitrite boils constantly and without being decomposed at 96° C. (205° F.) (W. H. Greene, 1879), or, according to

(Chapman (1867), between 98° and 99° C.; the vapor is orange-colored and has the density 4.03. Amyl nitrite burns with a bright fawn-colored and sooty flame. It is insoluble in water, but dissolves in all proportions in rectified spirit and other alcohols, in ethers, carbon disulphide, benzol, benzin, and other hydrocarbons. It dissolves fixed oils, fatty acids, phosphorus, and a small proportion of sulphur, caoutchouc, and gutta-percha. On exposure to air and light it acquires an acid reaction, and should therefore be preserved in small glass-stoppered vials kept in a cool and dark place—according to *P. G.* with a few crystals of potassium tartrate, whereby an undue amount of free acid will be prevented. In contact with potassa solution it is gradually decomposed, with the formation of amyl alcohol and potassium nitrite, the decomposition being accelerated by warming and in the presence of alcohol; the presence of nitrite is shown by adding to the alkaline liquid a little potassium iodide, then acetic acid to an acid reaction; an immediate separation of iodine will take place, and on the addition of gelatinized starch a deep-blue color will appear (distinction from nitrate). If it be added drop by drop to caustic potassa heated to fusion, potassium valerianate will be formed, frequently with the production of flame.

The commercial product is frequently very impure. Six samples examined by Dott (1878) yielded 85, 65, 47.5, 33.3, 11.5, and 6.7 per cent. of distillate between 90° and 100° C., and Dr. W. H. Greene (1879) found the boiling-point to rise from 70° to 180° C., and some samples to consist chiefly of amyl alcohol.

Tests.—Amyl nitrite should remain transparent or nearly so when exposed to the temperature of melting ice (absence of water).—*U. S.* On shaking 10 Ccm. of nitrite of amyl with 2 Ccm. of a mixture of 1 part of water of ammonia and 9 parts of water, the liquid should not redden blue litmus-paper (limit of free acid).—*U. S. and P. G.* On adding to amyl nitrite three times its volume of a mixture of equal parts of ammonia-water and absolute alcohol, followed by the addition of a little silver nitrate, the application of a moderate heat should cause neither a brown nor black color (absence of valeraldehyd).—*P. G.*

Allied Compounds.—AMYL NITRAS, nitrate of amyl, $C_5H_{11}NO_3$. It was discovered by W. Hoffmann (1848), and is most advantageously prepared, according to Chapman and Smith (1867), by dropping through a long tube, and *with constant stirring*, 50 Ccm. of amylic alcohol into 150 Ccm. of a mixture made of 1 volume of nitric and 2 volumes of sulphuric acid, and kept cool by ice and table-salt. Without any visible reaction an oily layer of amyl nitrate separates on the surface, which is obtained pure by washing with dilute potassa solution and water, drying with calcium chloride, and rectifying. It is a colorless oily liquid of a peculiar odor and sweet and burning taste. Its density at 15° C. is .902, and it boils at 147° C. (296.6° F.). It dissolves in glacial acetic acid, benzol, and in ethylic, methylic, and amylic alcohol, but not in water.

NITROPENTANE, $C_5H_{11}NO_2$, was obtained by Von Meyer and Stüber (1872) by treating nitrite of silver with amyl iodide. The liquid is isomeric with amyl nitrite, but boils between 150° and 160° C. (302° and 320° F.), and under the influence of nascent hydrogen yields amylamine. According to Dr. Greene, traces of it are present in commercial nitrite of amyl.

Physiological Action.—*On Animals:* Experiments made with this compound (which was introduced as an anæsthetic by Dr. Richardson in 1863) show that it is readily absorbed by all the tissues, is not an anæsthetic or a local irritant, and does not produce unconsciousness until its other effects are fully developed. It prevents the changes which give to arterial and venous blood their contrasting hues, and occasions a cyanotic tint of the tongue and other vascular parts. The blood in both sets of vessels acquires a brownish color. Primarily, it quickens the respiration, but its prolonged action retards the movements of the chest. It greatly lowers the animal temperature, especially when given in a lethal dose. These phenomena are explained by the fact, which was determined experimentally, that under the influence of the vapor the blood contains two-thirds less than the normal proportion of oxygen, and the hæmoglobin loses its power of crystallizing. This nitrite primarily dilates the capillaries and reduces arterial pressure, while the action of the heart, for this reason probably, becomes very rapid; but if the use of the nitrite is prolonged the pulse-rate is lowered. The cardiac pulsations are stronger, as well as more frequent, in proportion as the vascular resistance diminishes; and, according to Franck, the heart in each of its cycles receives and discharges as much blood as it did under normal circumstances. This agent is held, on the one hand, to increase the irritability of the spinal cord, upon the ground that animals under its influence pass into a tetanoid condition (Meyer and Friedrich), and on the other that it is a direct and paralyzing poison to the muscles (Pick).

On Man: When 5 or 6 drops of it are inhaled the heart becomes excited, the pulse rising from 70 to 160; its force, as measured by the sphygmograph, diminishes, but practically is increased, for all clinical observation proves that it directly or indirectly enables

the heart to overcome embarrassment; the skin, especially of the face, turns crimson; some vertigo is experienced, and the breathing is hurried as it is after rapid walking. If the dose is large the sight may be dimmed, and in the field of vision sometimes a yellow circle appears, surrounded by a violet border. It neither increases nor lessens general sensibility. In full doses it depresses the normal temperature by from 1° to 3° F. Sanders has recorded cases in which sudden collapse followed upon its administration, and Samelsohn one in which the usual flush was succeeded by deadly pallor, the pulse becoming thread-like and slow, the skin cold and clammy, and respiration difficult and gasping, although consciousness was retained. Others are referred to by Jastrowitz. Dugau (1879) relates that after continuing to breathe the vapor for a considerable time he suffered from distressing and irregular palpitation of the heart, with pallor, debility, vertigo, and loss of appetite. During the inhalation the patient is generally conscious of giddiness, a feeling of the head being inordinately large, a diffused glow, and throbbing of the heart and large arteries. It is alleged that the action of this medicine is exceedingly capricious—that while some persons can without injury inhale 30 or 40 drops, others are sensibly affected even by a fraction of a drop.

Dr. Senter has reported the case of a lady who swallowed a dessertspoonful (f5j) of nitrite of amyl. 25 minutes later she was vomiting, her face grayish-white, the pupils widely dilated, and the eyes glassy and rolling. The mouth was open, the breathing alternately rapid and slow, and then was almost suspended. The pulse, irregular and jerking at first, became very slow and hardly perceptible. The muscles were all relaxed; the skin, cold and sweating, exhaled an odor of amyl. The patient recovered under the use of coffee, laudanum, heat, friction, and flagellation (*Amer. Jour. of Phar.*, Mar. 1881, p. 137). In the case of a man affected with pulmonary phthisis death followed the inhalation of 7 drachms of nitrite of amyl (*Boston Med. and Surg. Jour.*, May, 1883, p. 526).

Nitropentane, according to Schadow, when respired by man in the dose of 18 drops for $5\frac{1}{2}$ minutes, produces no peculiar symptoms; in dogs and cats prolonged inhalations of the vapor induced dilatation of the pupils and epileptiform convulsions.

Uses.—The power of nitrite of amyl to dilate the capillaries is said to have suggested its use in *angina pectoris*, *epilepsy*, and other spasmodic diseases. It is certain that in many cases of the former disease the inhalation of 2 or 3 drops suffices to arrest the paroxysm of pain or materially to mitigate it. The various lesions which may give rise to *angina* render these differences of effect intelligible. In some cases, probably those which are either purely functional or connected with the less serious organic lesions of the heart and aorta, the habit of using the medicine appears to render the attacks both less frequent and less severe. But in course of time, like other nervines, its influence declines. The mode of action of the medicine in this disease appears to be anodyne, and at the same time antispasmodic. It should be very cautiously used, and most of all when there is reason to suspect degeneration of the arteries of the brain. In pure *neuralgia*, especially of the fifth nerve, it sometimes relieves the pain promptly; and the same may be said of *neuralgic headache* and of *gastralgia*. In *spasmodic asthma* also it frequently brings prompt relief in proportion as the character of the attack is nervous. In several cases it appears to have suspended dyspnoea produced by fatty degeneration and other debilitating lesions of the heart. Persistent *hiccup* has yielded to its use. It has also been used in *whooping cough*. In 1877 ten cases of the disease were reported by D. Bayles, who claimed for the nitrite a positive value "in allaying the violence and limiting the duration of the cough" (*Trans. N. Y. State Med. Soc.*, 1877, p. 181). In persistent *hiccup* occurring without known cause nitrite of amyl has arrested the attack after the failure of cauterization, atropia, and chloroform (*Med. Record*, xxii. 231). It has relieved infantile *spasm of the glottis* (Williams). In *syncope* from post-partum hæmorrhage it has restored consciousness and saved life (Köhler; Kerr), and dissipated the dizziness and *faintness* caused by anæmia or by such severe pain as *hepatic* and *renal colic* produce (Kurz). It may be believed that these effects are due to the power which the nitrite has of dilating the blood-vessels, for they are observed in other affections to which this explanation applies. One is *sea-sickness*, in which the subjective symptoms seem due to cerebral anæmia, and are promptly relieved by this medicine (Clapham, *Lancet*, June, 1879); another is the *vertigo* and *syncope* which accompany various obstructive or astyolic lesions, such as mitral insufficiency, dilatation, and softening of the heart. It may be added that this preparation has been used to distinguish anæmia from congestion of the brain—conditions which are often very much alike in their phenomena. The nitrite palliates the former, but aggravates the latter state. In *pneumonia* involving a large portion of both lungs, and therefore producing a relative debility of the heart and imper-

fect supply of blood to the brain, it has been given by the stomach with marked advantage (Keating). It is said that the chill of *intermittent fever* has been abruptly arrested by the inhalation of this vapor, while the febrile stage was correspondingly shortened; and also that a like effect has been produced in the paroxysm of *dysmenorrhœa* (*Boston Med. and Surg. Jour.*, Dec. 1881, p. 597). The medicine has been used to combat the *night-sweats* of phthisis, but in the reported cases (Murrell, *Practitioner*, xxiii. 97) the dose employed was too insignificant to be efficient and the results were mainly negative. There appears to be good reason for believing that it sometimes cures *chorea*, but for this purpose it must be administered two or three times daily for several days. Several cases of traumatic *tetanus* have recovered under its use; and since, in experiments upon frogs tetanized by strychnia, death was prevented by the use of nitrite of amyl until the elimination of the poison, it is probable that the same effect might ensue, and even more promptly, in man. In the cases of *tetanus* successfully treated by the nitrite it was administered two or three times a day, and in doses of only 5 drops. In *trismus nascentium* it has also been found to control the spasms. The same statement is true of *puerperal eclampsia*. In one such case the use of the medicine was followed by relaxation of the uterus and profuse hæmorrhage. In *infantile convulsions* its utility has been shown, even when the child was brought to death's door by a farrago of medicines, including chloral, chloroform, and morphia; and in *hydrophobia*, although incapable of staying the advance of death, it has enabled the patient to take food and drink and lessened the horror of impending dissolution. In *hysterical convulsions* it has also arrested the paroxysm, but in no degree modified the general course of the disease or lessened the frequency of the attacks. If we may trust the published reports, its influence upon *epilepsy* is more permanent and radical; it would seem not only to prevent the development of the paroxysms when applied early, but also to render their occurrence less frequent. This is particularly true of cases in which several successive convulsions make up the paroxysm. Necessarily, it must be most useful when the fit is preceded by an aura or other warning symptom; but even in those cases in which the fits are subintractant the remedy usually produces a very sensible amelioration. It is to be noted that when it is employed during the fit, and when the face is very livid, this color is gradually replaced by a vivid flush as consciousness returns. Epilepsy cannot be cured by this medicine. It has been employed to relieve *pain* of a more or less *spasmodic nature* occurring in the œsophagus, diaphragm, stomach, bowels, bladder, urethra, uterus, vagina, etc. A case of *blepharospasm* is recorded in which the patient is said to have been cured by its inhalation in very unusual doses—viz. from f5ss to f5j from one to three times a day for 4 successive days. A case of *strychnia-poisoning* in which the tetanic phenomena were very severe was cured by the repeated inhalation of nitrite of amyl, which effectually averted or greatly modified the fits as often as it was administered (Barnes, *British Med. Jour.*, Apr. 1, 1882). The same method has relieved *chordæ*. It has arrested the paroxysm of *intermittent fever* when inhaled during the cold stage in the dose of 4 drops. In a case of *exophthalmic goitre* 2 drops were found to be an excessive dose, and "one-tenth of a drop" was directed to be taken half an hour before eating, with complete relief of all the subjective symptoms (Blake). The patient was a nervous female.

One of the most important qualities of nitrite of amyl consists in the antagonism of its primary action to *chloroform syncope*. It is certain that chloroform contracts, and that nitrite of amyl dilates, the capillaries of the brain and of the skin of the face; under the former the patient grows pale, under the latter he is flushed. In experiments upon animals, if the nitrite be used in an excessive dose, cyanosis arises in consequence of venous engorgement. Experiments have also shown that if it is given, according to the latter method, to an animal already narcotized by chloroform, it deepens instead of relieving the narcotism, while if it be administered in moderate quantities, either by inhalation or hypodermically, it revives the heart's action and removes the pallor caused by the chloroform. These effects have been happily illustrated in at least eight cases of chloroform-poisoning. In all of them the patients were rescued from imminent death. The salutary or pernicious effects of the nitrite being due to the amount of it administered, we may explain why Testa should have fallen into the error of declaring that it intensifies the dangers which chloroform creates. Besides the cases just mentioned of its remedial power in chloroform syncope, others might be cited to show that it is equally efficacious when injected hypodermically in the dose of 3 minims (*Medical Record*, xxi. 335). The nitrite has also been used with advantage in poisoning by chloral (*British Med. Jour.*, June, 1879). Like alcohol and other excitants of the heart and nervous system, it has been found of service in various states of *exhaustion* and *typhoid depression*.

As its action is fugitive, its administration must in such cases be frequently repeated. It has been successfully employed in several cases of *carbonic acid* poisoning and to relieve insomnia produced by the *opium habit*. Imperfect vision due to insufficient blood-supply to the retina (*amblyopia*), and which strychnia has failed or ceased to profit, has sometimes improved under this medicine; and in many cases of subjective *noises in the ear* the repeated use of it has afforded great relief when the tinnitus has not been due to a mechanical cause. Applied locally, it is anodyne, relieving the pain of *headache*, *toothache*, *earache*, *neuralgia*, *dysmenorrhœa*, etc.

Administration.—Nitrite of amyl may be given in the dose of from 3 to 5 drops (Gm. 0.15–0.30) by the mouth, dissolved in a little aromatic spirit. Like most other medicines which act directly upon the nervous system, it rapidly becomes tolerated in increased doses. Dugan relates that in experiments on himself he could at first inhale no more than 5 drops, but he gradually became able to inspire the vapor largely without occasioning symptoms which in the beginning seemed alarming. Bourneville frequently gave it in doses of 20 drops. We have found but one case recorded of its fatal use, and that was from an excessive dose, mentioned above. It has sometimes been injected hypodermically in cases of chloroform-poisoning, and without occasioning any local irritation. Usually, nitrite of amyl is administered by inhalation, about 5 drops being poured upon the palm of the hand, a piece of sponge, or a folded napkin; or else it is carried in a well-stopped bottle (especially by epileptics), to be used when the fit threatens. Tubes and (still better) “tears” of glass containing about 5 drops (Gm. 0.30) each are also employed by the same class of patients, the glass being crushed in a handkerchief and its contents inhaled. It should rarely be used when syncope is produced by profuse hæmorrhage or when there is organic disease of the heart or brain.

AMYLENUM.—AMYLENE.

Valerene, *Pentene*, E.; *Amylene*, Fr.; *Amylen*, *Valeren*, G.
Formula C_5H_{10} . Molecular weight 70.

Preparation.—It was discovered by Balard (1844) by distilling amylic alcohol with a concentrated solution of chloride of zinc. Bauer (1861) recommends the leaving in contact for several days 2 parts of amylic alcohol with 3 parts of fused chloride of zinc, and then distilling until the temperature has risen to about 135° C. (275° F.). The distillate contains some amylic alcohol, water, and amylene with its polymers. All these impurities have a much higher boiling-point, and are removed by careful rectification in a water-bath and over chloride of calcium at a temperature not exceeding 40° C. (104° F.); it is more difficult to separate amyl hydride, which boils at nearly the same temperature.

Properties.—Amylene, thus obtained, is a thin, volatile, inflammable liquid having a disagreeable cabbage-like odor. It boils at about 35° C. (95° F.), has at 10° C. (50° F.) the specific gravity .6549, and is soluble in alcohol and ether, but insoluble in water. It is a mixture in varying proportions of two or three isomeric compounds boiling respectively at 35° and 37° C. (95° and 98.6° F.).

Amyl hydride, C_5H_{12} , which is contained among the most volatile portions of petroleum and in the light tar-oil of cannell coal, resembles the preceding, but has a more agreeable ethereal odor, recalling that of chloroform, and boils at 30° C. (86° F.).

Physiological Action.—This substance, which was introduced by Snow in 1856, was shown by him to produce unconsciousness and anæsthesia in animals very rapidly, but not in proportion to the amount inhaled, since a very large part of it was expelled without having been absorbed. It produced death suddenly by causing arrest of the heart. In the *surgical operations* in which it was used anæsthesia was observed to be complete in many instances before consciousness was lost, while under ether or chloroform unconsciousness precedes complete anæsthesia. Its action occurs more promptly than even that of either of the substances just named, but its effects pass off with like rapidity. It does not cause sickness at the stomach as readily as they do. But, whatever its advantages may have been, the occurrence of several cases of sudden death during its use caused it to be laid aside.

AMYLUM, U. S., Br.—STARCH.

Amylum tritici, P. G.—Wheat starch, E.; *Fécule* (*Amidon*) *de froment, de blé*, Fr.; *Stärke*, *Kraftmehl*, *Weizenstärke*, G.

Composition $C_6H_{10}O_5$. Molecular weight 162.

The fecula of the seed of *Triticum vulgare*. *Villars*, s. *T. sativum*, *Lamarch.* Bentley and Trimen, *Med. Pl.*, 294.

Nat. Ord.—Graminaceæ.

Origin.—Starch is found in most vegetables at some period of their growth, and exists in different plants in very different proportions. It is nearly always deposited in the cellular tissue, but is found suspended in the milk-juice of some plants. In many plants a considerable amount of starch is deposited in the root, rhizome, or tuber, or in the seed; in some cases, as in certain palms, it is largely found in the trunk previous to flowering. The mode of preparation must necessarily vary to a certain extent, but always consists in the comminution of the part of the plant by grinding or rasping, and in removing the coarse particles of tissue by sieves, and by subsidence from water, in which the starch remains suspended for some time. (For remarks on the origin and composition of wheat see FARINA TRITICI.)

Description.—From whatever source obtained, starch appears to the naked eye in the form of a fine white powder, the particles of which frequently adhere together superficially, so as to form irregular columnar masses. Under the microscope the powder is observed to consist of distinct grains of a peculiar shape and size, which vary with the plant from which the starch has been obtained. The smallest starch-granules observable with the aid of a microscope are globular in appearance, but the form of the larger granules, such as potato starch, arrow-root, etc., is quite characteristic, so that the origin of starch may by this means be detected with tolerable certainty.

Schleiden classified the starches thus:

1. Without distinct shape (non-mealy sarsaparilla, *Carex arenaria*).

2. Mostly single grains: *a*, roundish, and without or oftener with a small nucleus; layers indistinct (maize, rice); layers distinct and grains ovate (potato, arrow-root), conchoidal (lily) or subconical (bletia); nucleus elongated (pea, bean) or cup-shaped (orris); *b*, lenticular, layers more or less distinct (wheat, rye, barley); *c*, very flat, layers distinct (Zingiberaceæ); *d*, stick-like, and layers distinct or nucleus elongated, or shape irregular (euphorbia).

3. Compound grains: *a*, without nucleus (bryony, sarsaparilla); *b*, with nucleus, and this small (manihot), large and radiate (colchicum), or cup-shaped (anatherum), forming irregular groups (arum), or several small grains united with a large one (sago).

The granules are evidently made up of layers, apparently differing somewhat in density, and more or less concentrically arranged around a nucleus or hilum, which in many cases is not in the centre, but near the margin or one end of the granule. With respect to the relative age of the different layers, the fact that the innermost ones are softer or less dense is regarded by Schleiden, Payen, Nägeli, and others as conclusive evidence that the outer ones were first deposited, and that those near and around the hilum originated later; while Fritzsche, Berg, and others, on the contrary, find that this condition is a proof of the external growth of the granules by deposits of fresh and denser layers around the more or less gelatinous nucleus. All these layers are considered by many investigators to be of the same composition, and to differ from each other mainly in the amount of moisture retained by them. Opinions, however, in relation to the existence of an enveloping membrane differing in composition are considerably at variance with one another. Those investigators who explain the formation of the starch-granules by external additions reject its existence, and, according to Schleiden, the denser outer layer of the granule which is first deposited is uniform and of precisely the same chemical behavior as the remainder. Payen, Persoz, and Nägeli, on the other hand, find that the starch proper has been deposited within a very thin membrane which has some of the characteristics of cellulose. If starch is acted upon by being digested with saliva, pepsin, or bile, it is dissolved, according to Nägeli, with the exception of a minute residue which does not swell on being boiled with water and requires to be treated with sulphuric acid before it is colored blue by iodine, but dissolves in ammoniacal solution of cupric oxide. For this outer membrane the name *amylin* has been proposed, while the portion soluble in hot water has been named *granulose* and *amidin*. The chlorides of zinc and calcium dissolve starch completely without leaving any residue.

Wheat starch, when viewed under the microscope, is found to consist of nearly circular and flat or lenticular granules, the largest of which are about $\frac{1}{1000}$ inch in diameter, and are mixed with many minute granules, but with a few of an intermediate size. The hilum, if observable, is near the centre of the circle, the indistinct layers forming nearly uniformly concentric rings.

Rye starch, from *Secale cereale*. *Linné*, consists of small and large granules, the latter

varying between oblong-ovate and lenticular in shape. The layers are concentric and rather indistinct; the hilum is near the centre, and mostly with 3 to 5 or 6 rays.

Preparation.—Wheat or other grain is soaked in warm water, to which sometimes an alkali is added, until the outer coating has become soft; it is then ground under water, and washed upon suitable sieves with pure water, with which the starch passes through and is collected by subsidence in suitable tanks, the alkaline water retaining the gluten; or the latter is removed by allowing it to undergo decomposition, when acetic, butyric, or lactic and other acids are produced. The gluten need not be destroyed, but may be obtained as a by-product; for this purpose wheat flour is made with water into a stiff dough; this is set aside for 2 hours, and then placed upon a fine wire sieve, where it is kneaded under a thin stream of water until the latter no longer becomes milky; nearly the whole of the gluten will remain upon the sieve. After sufficient washing with pure water the starch is drained in boxes, cut into cubical blocks, and dried in properly constructed drying-chambers.

Properties.—Starch forms a white, inodorous, and tasteless powder, with a peculiar slippery feel between the fingers. Exposed to the atmosphere, it contains from 10 to 13 per cent. of moisture, which is given off at 100°C . (212°F .) and is reabsorbed on exposure. The spec. grav. of starch is about 1.5, but after complete drying is increased to 1.56. It is insoluble in ether, alcohol, and cold water; the last-mentioned liquid, however, when triturated with starch, so that some of the granules are ruptured, evidently dissolves a little, since it acquires, after filtration, a blue color on the addition of iodine. *Soluble starch* is obtained, according to Maschke, by the prolonged heating of starch to 100°C . (212°F .). When heated to between 160° and 200°C . (320° and 392°F .) it is gradually converted into *dextrin* (see below). Starch becomes soluble in cold water in the presence of the chlorides of zinc and of calcium and of other deliquescent or freely soluble salts. Its solution in hot water gelatinizes on cooling, the jelly of wheat starch being milk-white—that of potato starch, particularly when made with much water, being more translucent. On heating starch with glycerin a solution is obtained which, according to Zulkowski (1875, 1880), contains soluble starch, obtainable by diluting with water and precipitating the clear filtrate with alcohol. Potato starch is easily converted into the soluble form, but wheat starch requires a prolonged heating, and rice starch is thus changed with still greater difficulty.

FIG. 14.

Wheat Starch.

FIG. 15.

Corn Starch.

FIG. 16.

Rice Starch.

Each magnified 250 diameters.

Mucilage of starch, when heated to about 160°C . (320°F .), or when boiled with very dilute sulphuric acid, or when digested with diastase at about 70°C . (158°F .), is converted, according to Musculus (1860), first into *maltose*, $\text{C}_{12}\text{H}_{22}\text{O}_{11}$, which is probably a compound of *dextrin*, $\text{C}_6\text{H}_{10}\text{O}_5$, and *dextrose*, $\text{C}_6\text{H}_{12}\text{O}_6$, the former passing finally likewise into glucose. Iodine imparts to starch in the presence of water, and to starch-mucilage, a blue color which disappears on the application of heat, but reappears on cooling. Bromine colors the starch brown-yellow. Fuming nitric acid transforms starch into *xyloidin*, $\text{C}_6\text{H}_5(\text{NO}_2)_3$, which is a white, tasteless powder, insoluble in alcohol, but softening in boiling water. A filtered solution of starch in water yields with tannin a flocculent precipitate which is soluble in boiling water. When incinerated, starch should leave not over 1 per cent. of ash.

Preservation.—All starches and farinaceous substances should be kept in a dry place. When confined in a damp atmosphere they acquire a musty odor, which may be removed by repeated washing with pure water and rapid drying.

Pharmaceutical Uses.—Starch is sometimes employed as an absorbent powder for preserving pills; it is contained in the following preparations: *Amylum iodatum*, *U. S.*; *Glyceritum* (*Glycerinum*) *amyli U. S.*, *Br.*; *Mucilago amyli*, *Pulvis tragacanthæ comp.*, *Br.*

Other Starches.—1. *AMYLUM MAYDIS*.—Corn starch, *E.*: Fécule de maïs, *Fr.*: Maisstärke, *G.* From the seed of *Zea Mays*, *Linné*. Bentley and Trimen, *Med. Pl.*, 296. Nat. Ord. Gramineæ.—The plant known as *maize* and *Indian corn* was found in extensive cultivation at the time of the discovery of America, and was from here introduced into Europe: it is said to have been introduced into China from Central Asia. The starch-granules are more uniform in size, but only about two-thirds as large as those of wheat starch: they are irregularly angular, rounded on the edges, and occasionally oblong muller-shaped, with a usually slit hilum and indistinct layers.

2. *AMYLUM ORYZÆ*.—Rice starch. Rice flour, *E.*: Farine de riz, *Fr.*: Reisstärke, *G.* From the seed of *Oryza sativa*, *Linné*. Bentley and Trimen, *Med. Pl.*, 291. Nat. Ord. Gramineæ.—The rice-plant is a native of India, has been cultivated from a very early period, and has been introduced into most tropical and subtropical countries. Rice of commerce consists of the seeds deprived of the persistent palææ and of the integuments; it is oblong or subcylindrical in shape, about $\frac{1}{4}$ inch (3 Mm.) or more in length, translucent, and furrowed on one side. Rice starch consists of polygonal granules less than one-fifth the diameter of wheat starch, and smaller than all other commercial starches, but mostly united to larger grains.

3. *AMYLUM SOLANI*.—Potato starch, *E.*: Fécule de pommes de terre, *Fr.*: Kartoffelstärke, *G.* From the tubers of *Solanum tuberosum*, *Linné*. Nat. Ord. Solanaceæ.—The potato-plant grows wild in the mountainous districts of Peru and Chili, and several tuber-bearing species of *Solanum* are indigenous to the mountains of New Mexico and Arizona. The potato was brought to England from Virginia in 1586, and is at present extensively cultivated in many varieties in most countries of the temperate zones; its starch is largely manufactured and used in Europe, and is sometimes substituted for arrow-root or used for adulterating it. The granules are of two sizes, a portion being small and subspherical, another portion larger than maranta starch, of an ovate or irregular oval shape, marked with rather coarse concentric lines, and with an inconspicuous hilum at the narrow end.

4. *AMYLUM MARANTÆ*, Maranta, *U. S.* 1870.—Arrow-root, *E.*, *Fr.*, *G.*; Salep des Indes occidentales, *Fr.*: Marantastärke, *G.* From the rhizome of *Maranta arundinacea*, *Linné*. Bentley and Trimen, *Med. Pl.*, 265. Nat. Ord. Marantaceæ.—The plant is indigenous to the West Indies and tropical America, and is largely cultivated in the Bermudas, in Georgia, Jamaica, St. Vincent, and in Brazil. It is a perennial herb, with a branching, fleshy, cylindrical rhizome covered with whitish scales or annulate with their scars. The slender branching stem is 5 to 6 feet high, has thickened nodes, ovate lanceolate leaves with long sheaths, and small whitish flowers, usually in pairs at the ends of the branches. *M. indica*, *Tussac*, is now regarded by botanists as being a smooth and narrower-leaved variety of the preceding; it is found in Bengal, Java, and the Philippines, and has been introduced into tropical Africa; the *Natal* and *East-India* arrow-root is obtained from it, but the latter sometimes consists of the starch of *Curcuma leucorrhiza* and *C. angustifolia*, *Roxburgh*, which is in flattened elliptic or elongated ovate granules marked with numerous fine lines and at the narrow end with a hilum. When about a year old the rhizomes of maranta are dug up, carefully cleaned from the scales, well mashed, and either ground in a mill or rasped until reduced to a pulp, which is suspended in water, the fibrous portion being either separated by hand or by sieves. The starch which settles from the water is repeatedly stirred with fresh portions of clean water, finally allowed to settle, and dried with a gentle heat. The rhizomes yield from 13 to 20 per cent. of fecula. (See papers by Robert Battay in *Proceedings of the Amer. Pharm. Assoc.*, 1858, p. 332, and by W. Eberhard in *Archiv d. Pharm.*, 1868, vol. clxxiv. p. 257.) The importation of arrow-root into the United States amounted to over 1,500,000 pounds in 1876, and decreased to 69,206 pounds in 1881 and 77,192 pounds in 1882.

Arrow-root is pulverulent or in small irregular lumps, less than $\frac{1}{4}$ inch thick, white, opaque, tasteless, and inodorous. Under the microscope it is seen to consist of ovate or somewhat oval granules, the layers of which are marked by fine but distinct lines, and have usually upon the broader end a small nucleus or a transverse fissure; the granules are nearly uniform in size.

Tests.—According to the German Pharmacopœia of 1872, 1 part of arrow-root gives with 96 parts of boiling water a moderately thin, pellucid mucilage; and when it is agitated for 10 minutes with a mixture of 2 parts of hydrochloric acid and 1 part of water, nearly the whole of the starch should separate unchanged and without the formation of a mucilage or the production of an herbaceous odor. Schaer (1875) showed that some samples of maranta starch yield in a short time a turbid jelly which gradually becomes

FIG. 17.

Potato Starch.

FIG. 18.

Maranta Starch.

FIG. 19.

Curcuma Starch.

limpid, while in most cases it separates unchanged, but is partly dissolved within 24 hours. This difference is probably due to climatic influences. The starches of manihot and curcuma have a similar behavior; wheat starch yields no jelly, but after several hours a strongly opalescent solution. Potato starch, however, is readily transformed into a thick, almost clear jelly, forming a complete solution in a few hours, and having a strong herbaceous or bean-like odor.

5. *AMYLUM CANNÆ*, *Canna*. *U. S.* 1870.—*Canna* starch, *Tous-les-mois*, *Toulema*, *E.*; *Amidon de canne*, *Fécule de Tolomane*, *Fr.*; *Cannastärke*, *G.* From the rhizome of (probably) *Canna edulis*, *Ker.* Bentley and Trimen, *Med. Pl.*, 266. *Nat. Ord.* Marantaceæ, *Cannæ*.—This showy plant is indigenous to Peru and Brazil, and is cultivated in St. Kitts and other West Indian islands. *Canna* starch is a white powder having a satiny lustre; its granules are the largest among the commercial starches, flattish, usually oblong or ovate, but variable in outline, with the inconspicuous nucleus or hilum mostly near the narrowed end, and with numerous concentric rings. *Canna* starch contains about one-sixth of its weight of hygroscopic water, and yields with 20 parts of boiling water a jelly which is considerably more tenacious, but less clear and transparent, than that of arrow-root.

FIG. 20.

Canna Starch.

Pohl, s. *Janipha* (*Jatropha*, *Linné*), *Manihot*, *Kunth*. Bentley and Trimen, *Med. Pl.*, 235. *Nat. Ord.* Euphorbiaceæ.—The plant, also known as *mandioc* and *manioc*, is probably indigenous to Brazil, where it has been cultivated from a remote period. It has been introduced into other parts of tropical America, into Florida, Africa, and the East Indies. Its fleshy, tuberous roots attain a length of 40 inches (1 M.), and contain a milky juice which is poisonous from the presence of hydrocyanic acid. E. Francis (1882) found cassava-root to yield on an average .0275 per cent., and the sweet cassava .0168 per cent., HCY. The sweet cassava is *Manihot palmata*, *J. Mueller*, s. M. Aipi, *Pohl*, s. *Jatropha dulcis*, *Gmelin*. This and another species, *Manihot carthaginensis*, *J. Mueller*, s. *Jatropha Janipha*, *Linné*, are used like the preceding. On grating the roots, expressing the poisonous juice, drying the residue and grinding it, *cassava meal* is obtained, which, when baked in thin cakes, furnishes *cassava bread*. From the expressed juice, and by washing the meal with water, on standing the starch is deposited. On drying this starch while still moist on heated plates *tapioca* is obtained.

FIG. 21.

Cassava Starch.

Cassava starch forms a white powder, which under the microscope is seen to consist of muller-shaped granules; these, viewed from one end, have the appearance of spherical grains. The nucleus is small, circular, or often elongated, sometimes radiate, and the different layers are indistinctly marked. The grains were originally united in groups of two to four, but in the commercial article are mostly separate. Their size is usually less than half that of potato starch. *Tapioca* (*U. S.* 1870) is in irregular opaque or somewhat translucent pieces, which consist of the same starch-granules partly distended, ruptured, and agglutinated. It is inodorous, has an insipid taste, and agrees in chemical behavior and composition with other starches.

FIG. 22.

Altered Starch-granules from Tapioca.

7. *Sago*, *U. S.* 1870.—*Sago*, *E.*, *G.*; *Sagou*, *Fr.* From the pith of *Metroxylon Sagu*, *Rottboell* (s. M. *Sago*, *Koenig*, M. *læve*, *Martius*, *Sagus lævis*, *Blume*). *Metz*, *Rumphii*, *Martius* (s. *Sagus Rumphii*, *Willdenow*, S. *genuina*, *Blume*), *Sagus farinifera*, *Lamarck*, *Arenga saccharifera*, *Labillardière* (s. *Saguerus Rumphii*, *Roxburgh*), and of other palms. Bentley and Trimen, *Med. Pl.*, 278. *Nat. Ord.* Palmæ.—The sago-palms inhabit the East Indian and Polynesian islands, and are extensively cultivated. They are mostly trees of medium height, but with a thick stem, containing a large amount of parenchyma-tissue, the cells of which are filled with starch. When of sufficient size the tree is cut down, split lengthwise, and the pith removed, powdered, and washed with water to remove woody tissue and other impurities. The dry starch is known as *sago meal*. This is granulated by passing the sufficiently damp meal through a sieve, the globular pieces dropping into a shallow pot suspended over a fire, where they are dried with constant stirring. While flowering the *Arenga* furnishes a juice rich in sugar.

FIG. 23.

Sago Starch.

tion it is somewhat diaphanous, and when examined under the microscope some of the starch-

granules are seen to be distended and partly ruptured. Sago starch consists of irregularly ovate, oval, or elliptical grains, often with a roughish surface; the hilum is located near one end, and is naturally small and circular, but in sago is often slit in one or more directions from the effect of heat. The end opposite the hilum is always more or less truncate or flat and muller-shaped. *Fuctitious sago*, which is made in Europe of potato starch, is best recognized by means of the microscope.

The granules of *Tahiti arrow-root*, which is obtained from *Tacca pinnatifida* and *oceanica*, *Forster*, and which is now rarely seen in commerce, are of about the same size as those of cassava starch, but are flattened and angular.

Derivative of Starch.—DEXTRINUM, *Dextrin*, $C_6H_{10}O_5$. Heat in a steam-bath, with frequent stirring, a mixture of 150 parts of starch, 750 parts of distilled water, and 4 parts of oxalic acid, until starch can no longer be detected by solution of iodine; then neutralize the acid with pure calcium carbonate, and after 2 days filter, evaporate, and dry at a gentle heat.—*P. G.*, 1872. On a large scale dextrin is prepared by heating starch in a cylinder or flat vessel to a temperature between 225° and 260° C. (437° and 500° F.); the yellowish product thus obtained is known in commerce as *British gum*. White dextrin, resembling starch in appearance, is manufactured by Henzè's process: 1000 parts of starch are mixed with diluted nitric acid, made from 2 parts of nitric acid sp. gr. 1.4 and 150 parts of water; the mixture is formed into cakes; these are dried in the air, then slowly heated to about 80° C. (176° F.) until the acid has been expelled, and powdered; on exposing the powder for from 60 to 90 minutes to a temperature between 100° and 110° C. (212° and 230° F.) the conversion into dextrin will be completed. It may be purified and freed from sugar, according to Hager (1870), by dissolving 10 parts of it in 18 parts of distilled water by agitation, straining if necessary, and mixing the solution with about 2 volumes of alcohol; the doughy precipitate is redissolved in a little distilled water and the solution dried upon glass. Dextrin is granular or a whitish or pale-yellowish amorphous gummy mass, readily soluble in water, but insoluble in alcohol and ether; its solution is dextrogyre and does not reduce an alkaline solution of copper.

Medical Action and Uses.—Starch is applied in dilute decoction as a demulcent to protect irritated surfaces upon the skin and in the digestive canal. As a powder it is extensively employed to shield the skin from the action of the air, to diminish the friction of contiguous surfaces, and to promote the healing of excoriations. Thus it may be used to allay the itching and burning of the skin in *erythema*, *urticaria*, *erysipelas*, and *small-pox*. In the form of a thick mucilage it has been employed to prevent pitting in the last-named disease. Bandages saturated with starch-mucilage made with hot water are used in dressing *fractures* and other injuries and diseases of the bones in which absolute rest of the injured part is required; or the mucilage is smeared on the outer surface of the bandage as it is applied to the affected part. This dressing dries slowly, and should be kept at perfect rest for nearly 24 hours. Starch-mucilage is constantly employed as a lenitive injection in inflammations of the *rectum* and the *bladder* and as a vehicle for applying narcotic and other substances to those parts. Mixed with water, starch is the best antidote to the caustic action of *iodine* upon the stomach, as it forms with this substance a bland compound. It also forms the surest test of the presence of iodine in the urine and other secretions by striking with it a characteristic blue color. Starchy food is to be avoided in fermentative *dyspepsia*, in consequence of its liability to undergo fermentation.

The fecula of *canna* has the nutritious and demulcent qualities of starch in general. As the purest natural form of starch, *arrow-root* is nutritious and demulcent, and does not, like potato starch, irritate the bowels. Hence it is extensively used in *febrile affections*, especially in those involving the stomach and bowels, and is also a favorite food for infants at weaning-time. It is prepared by mixing a tablespoonful of arrow-root with sufficient cold water to reduce it to a paste, and then gradually adding a pint of boiling water or milk, or a due proportion of each, stirring the mixture the while. It may then be sweetened. Cream is sometimes mixed with the watery mucilage when the stomach or bowels are irritable. In exhausting diseases a little wine may be added, with cinnamon or nutmeg. *Sago* is demulcent and nutritious, and forms an excellent food for the sick when the digestive organs are feeble or fever contraindicates the use of stimulant diet. It is more generally acceptable to the palate than arrow-root or tapioca, and is more digestible than rice. The demulcent and nutritive properties of *tapioca*, as well as the poisonous properties of the juice of the plant that yields it, were known in the seventeenth century. The qualities of the juice are due to the prussic acid it contains. The symptoms it produces are identical with those of prussic acid, as spasmodic constriction of the throat, convulsions, coma, and death with dilated pupils. Tapioca is chiefly used for making puddings and as a simple mucilaginous food for the sick and for infants.

A palatable form of it is prepared as follows: Take a tablespoonful of tapioca; macerate it in a pint of warm water for an hour, and then boil it for 10 minutes, stirring all the time. Sugar, lemon-juice, or some fruit-syrup, nutmeg, wine, etc., may be added for flavoring and to neutralize the pasty and mawkish taste of the starch.

AMYLUM IODATUM, U. S.—IODIZED STARCH.

Amyli iodidum, Ioduretum amyli.—*Iodide of Starch*, E.; *Iodure d'amidon*, Fr.; *Jodstärke*, G.

Preparation.—Starch 95 parts; Iodine 5 parts; Distilled Water a sufficient quantity to make 100 parts. Triturate the iodine with a little distilled water; add the starch gradually, and continue triturating until the compound assumes a uniform blue color, approaching black. Dry it at a temperature not exceeding 40° C. (104° F.) and rub it to a fine powder. Iodized starch should be preserved in glass-stoppered vials.—U. S.

That starch produces a blue or violet-blue color with iodine was observed by Colin and Gaultier de Claubry in 1814, and that the color of starches of different origin and age may vary to some extent was subsequently shown by Nägeli and others. Liebig regarded iodized starch as a mere mixture of starch with finely-divided iodine, and this view is now generally adopted. Payen and Fritzsche, however, believed it to be a definite compound, $(C_6H_{10}O_5)_{10}I$, and Bondonneau gives it the formula $(C_6H_{10}O_5)_5I$, equal to 13 per cent. of iodine, the latter being dissolved by alcohol, but not by potassium iodide, benzoin, sulphide of carbon, or other solvents. According to the process adopted the amount of iodine varies, and, though generally about 7.5 per cent., may be as low as 3.2 per cent. (Sonstadt) or, as obtained by Lassaigne, as high as 41.75 per cent. The official iodized starch contains 5 per cent. of iodine. Fritzsche obtained his supposed definite compound by adding tincture of iodine to a filtered solution of starch in concentrated hydrochloric acid. Bondonneau (1878) dissolved the starch first in caustic soda, and precipitated the slightly acidulated solution with tincture of iodine. According to Quesneville (1868), it may be obtained both in a soluble and an insoluble state as follows: 1050 parts of starch and 100 parts of iodine, both in fine powder, are well mixed, and then triturated with a mixture of 400 parts of water and 100 of alcohol, the liquid to be added gradually; the whole is left in contact for 15 or 20 days, and afterward carefully dried. Thus prepared, it is a dark blackish-blue powder, has no odor of iodine, and contains 10 per cent. of this element. To obtain it soluble it is heated in a porcelain or enamelled dish over a slow fire and with continued agitation until a pungent odor commences to be given off. It may be still further purified by making a concentrated solution in warm water, precipitating the clear liquid by alcohol, drying, and powdering the precipitate.

Properties.—Iodized starch is a dark-blue powder having the odor of iodine in a mild degree. Exposed to the sunlight, it is decolorized; when heated with water to 65° C. (149° F.) it becomes colorless, and blue again on cooling; but when heated to boiling, iodine is given off, and may be completely expelled by continuing the heat for a sufficient length of time.

The production of iodized starch is one of the most delicate tests for the recognition of starch as well as of iodine, the limits of the reaction being influenced by the temperature. Fresenius (1857) ascertained that 1 part of iodine may thus be detected at 0° C. (32° F.) in 660,000 parts of water, at 13° C. (55.4° F.) in 330,000 parts, at 20° C. (68° F.) in 264,000 parts, and at 30° C. (86° F.) in 132,000 parts of water. For detecting minute quantities of starch or iodine the test should obviously be applied at as low a temperature as possible.

Action and Uses.—This preparation was proposed as a means of introducing a large amount of iodine into the system without irritating the stomach. Buchanan, who proposed it, gave as much as an ounce of it three times a day without any unpleasant symptoms. In 1879, Bellini recommended it as an antidote for *poisons* generally, stating that it formed insoluble compounds with many of them, and that in cases of poisoning by salts of lead or mercury it aids in their elimination (*Boston M. and S. Jour.*, Aug. 1879, p. 267). McCall Anderson used it with advantage in *lupus erythematosus*, giving a heaped-up teaspoonful several times a day.

ANACARDIUM.—CASHEW-NUT.

Acajou à pommes, Fr.; *Caschnuss*, G.

The fruit of *Anacardium occidentale*, *Linné*, s. *Cassuvium pomiferum*, *Lamarch*.

Nat. Ord.—Terebinthaceæ.

Origin.—This is the fruit of a small tree with coriaceous, shining, oval, entire, and very obtuse leaves, and loose racemes of small whitish or purplish flowers. After fructification the pedicels of the pistillate flowers become large, fleshy, pear-shaped, and edible, having an acidulous taste, and bear upon their summits the nut-like fruit. The plant is indigenous to tropical America, and has been naturalized in some portions of Africa and the East Indies.

Description.—The fruit is about an inch (25 Mm.) long, somewhat less broad, and about one-third of an inch (8 Mm.) thick. It is kidney-shaped, convex on the back, with a scar on one of the rounded ends, of a gray-brown color, and inodorous. The shell is hard and brittle, and contains in the mesocarp a very acrid oily liquid which in contact with air turns black. The single white seed has the shape of the fruit and a mild oily taste.

Constituents.—The cotyledons contain some bland fixed oil. Vieira de Mattos (1831) found in the pericarp tannin, gallic acid, soft acrid resin, etc. The brown oil was found by A. Basiner (1881) to be soluble in potassa, with a red color, darkening on exposure, and its alcoholic solution to yield a red precipitate with basic lead acetate. Staedeler (1847, 1848) separated the vesicating principle, *cardol*, $C_{21}H_{30}O_2$, as a yellowish or reddish oil, evolving, when heated, a faint aromatic odor, and readily soluble in alcohol and ether. It is obtained from the ethereal extract, which is washed with water to remove tannin, dissolved in alcohol, and digested, and afterward boiled with hydrate of lead to remove *anacardic acid* and ammonia salt. The remaining color is removed by a little basic lead acetate. Cardol may be separated from mixtures by extraction with glacial acetic acid and subsequent agitation of the latter with benzol (Basiner). Anacardic acid, when pure, is white and crystalline, has an aromatic afterward burning taste, but is not vesicating. Cazeneuve and Latour (1875) found *catechin* in the wood of the cashew tree.

The *Oriental cashew-nut*, known as *Anacardium orientale*, is the fruit of *Semecarpus Anacardium*, *Linné filius*, s. *Anacardium latifolium*, *Lamarck*, a tall tree of India. The nut is about an inch (25 Mm.) long, nearly heart-shaped, flattish, obtuse, smooth, glossy, and black. The pericarp and cotyledons have the same properties and probably the same constituents as the preceding; but Basiner (1881) ascertained that the brown oil of the mesocarp dissolves in potassa with a green color, and its alcoholic solution turns black with basic lead acetate.

Medical Action and Uses.—Although the kernel, when roasted, and even when raw, is edible, the juice furnished by the rind of the cashew-nut is acrid and almost caustic, and has been used for destroying *corns*, *warts*, and *vegetations* and as an epispastic. But the latter application of it is very objectionable, not only because it is slow in its operation, but because the juice is apt to be carried by the patient's fingers to the genitals and other parts and give rise to a very painful and persistent eczematous eruption. The liquid contained in the blisters has a similar property. A like effect is produced by the fumes arising from the nuts while roasting. The remedies are such as are employed in poisoning by toxicodendron. A weak solution of tincture of iodine may also be applied with advantage. A case in which this topical remedy was successfully used was caused by using heat to reduce a liquid extract of the drug to a solid consistence (*Am. Jour. Pharm.*, June, 1881, p. 281). It is stated (Buchheim) that the oil has a very faint and hardly acrid taste, and that 3 or 4 drops of it may be swallowed without marked effects. This contrast with its action upon the skin is attributed to its total insolubility in the watery fluids of the digestive canal, while upon the dry skin nothing interferes with its irritant action. It has, however, been used as a *vermifuge*. According to Basiner, the subcutaneous injection of small doses of cardol produces on cold-blooded animals paresis, increasing to paralysis, of the extremities, stupor, paralysis of respiration, and tetanic spasms. In warm-blooded animals large doses are not lethal, but stupor, paralysis of the extremities, and diarrhœa occur, and after death congestion of the intestinal lining is found. Cardol seems to be excreted chiefly with the urine, but partially also with the feces. Applied on a small piece of lint to the skin of the breast, it raised a watery blister in 14 hours. The brown-black oil of the Oriental cashew-nut occasioned within 12 hours a black blister, and on the following day eczematous vesicles appeared in the neighborhood, and afterward extended to the arm, hands, face, abdomen, and penis, the poison no doubt being carried thither by the fingers. On the sixth day scales began to form on the breast and forehead; micturition was painful, the urine red-brown; the stools bloody and very painful. More than 2 weeks elapsed before the sores were healed (*Basiner, Am. Jour. Pharm.*, Mar. 1882, p. 131).

ANDIRA.—CABBAGE TREE BARK.

Ecorce de geoffrée, Fr.; *Kohlbaumrinde*, *Wurmrinde*, G.

The bark of Andira (Geoffroya, *Swartz*) *inermis*, *Kunth*, and of Andira (Geoffroya, *Lamarck*) *retusa*, *Kunth*.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—Both species are medium-sized trees, with impari-pinnate leaves, terminal racemes of red flowers, and roundish hard one-seeded pods. The first-named species is a native of Jamaica and other West Indian islands, the second is found in Surinam and Cayenne.

Description.—*Jamaica* cabbage tree bark occurs in long pieces about one-eighth of an inch (3 Mm.) thick, gray or whitish, and fissured externally, upon the inner surface brownish and striate, internally brown or brownish, radially striate, and with yellowish bast-fibres in tangential rows, which cause the laminated fibrous appearance of the bark when broken transversely. It yields a grayish powder, and has a feeble but disagreeable odor and a mucilaginous bitter taste.

Surinam cabbage tree bark resembles the preceding, but is internally dark red-brown, has a checkered and glossy appearance on transverse section, yields a cinnamon-colored powder, is nearly inodorous, and has a bitterish acrid taste.

Constituents.—Hüttenschmid (1824) discovered in each of the cabbage tree barks an alkaloid, which he named *jamaicine* and *surinamine*, the former of which was proved by Gastell (1866) to be identical with berberine. The latter is described as being in fine white needles, scarcely soluble in cold water, alcohol, and ether, but readily soluble in boiling water. The other constituents are those commonly occurring in plants; the bark from Surinam contains also notable quantities of tannin.

Allied Species.—*AND. ANTHELMINTICA*, *Bentham*, s. *Geof. vermifuga*, *St. Hilaire*, is a tall forest tree of Brazil. The seeds, known there as *angelim amargosa*, are of the size of a nutmeg, oblong, somewhat horny, yellowish, usually in transverse or longitudinal sections, whitish internally, inodorous, and almost tasteless. They are regarded as anthelmintic. According to Peckolt (1858), the wood contains *andirin*, a brown-yellow coloring principle, soluble in water and fixed and volatile oils, but insoluble in alcohol and ether. The drastic and anthelmintic principle is an acrid resin soluble in ether and alcohol. (See also *ARAROA*.)

Medical Action and Uses.—In medium doses andira is said to occasion nausea, vomiting, diarrhœa, fever, and delirium, especially when given in cold infusion. Sometimes it augments the urinary secretion. It was used in the West Indies as a remedy for *lumbricoid worms*. The dose is stated to be from 5 to 10 grains (Gm. 0.30–0.60) for children, and from 10 to 30 grains (Gm. 0.60–2.00) for adults. An infusion or decoction was made with an ounce of the bark in 8 fluidounces of water (Gm. 30 in Gm. 250), and was given in tablespoonful doses.

ANETHI FRUCTUS, *Br.*—DILL-FRUIT.

Aneth, *Fenouil puant*, Fr.; *Dill*, G.

The fruit of *Anethum* (*Peucedanum*, *Hiern*) *graveolens*, *Linné*. Bentley and Trimen, *Med. Pl.*, 132.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—The plant is indigenous to Southern Europe and Asia Minor, and is cultivated in other parts of Europe and in this country. It is an annual, with finely-divided glaucous leaves, growing to the height of about 2 feet (60 Cm.) and bearing yellow flowers.

Description.—The fruit is oval, about one-eighth to one-fifth of an inch (3 to 5 Mm.) long, dorsally compressed, of a brown color, and separates when ripe into two mericarps, which are flat upon their face and somewhat convex upon the back. The three dorsal ribs are fili-

Anethum: fruit, 3 diameters; transverse section, 5 diameters.

form and rather sharply keeled, while the two lateral ones are extended into a light-colored broad membranous margin. The fruit cultivated in India is narrower, more convex on the back, and is less winged than the European fruit. Of the six dark-colored vittæ, two are found on the commissure, the remaining four in the furrows of the back. The odor and taste of dill are aromatic.

Constituents and Uses.—The fruit contains a fixed and 3 to 4 per cent. of an oxygenated volatile oil (see *OLEUM ANETHI*), to which its medicinal properties are due. It is used for preparing dill-water.

Medical Action and Uses.—Dill is not much used in this country. It has the properties of the aromatic stimulants generally, and is employed to relieve *flatulent colic* and *hiccup* occasioned by gastric indigestion and flatulence. Dill-water, the usual form of exhibiting it, may be given in doses of a fluidrachm (Gm. 4) or more. The essential oil may likewise be used in the dose of from 2 to 5 minims (Gm. 0.10–0.30) with sugar or incorporated with magnesia.

ANGELICA.—ANGELICA-ROOT.

Racine d'angélique, Fr.; *Engelwurzel*, G.

The root of (1) *Archangelica officinalis*, *Hoffmann*, s. *Angelica Archangelica*, *Linneé*, s. *Ang. officinalis*, *Moruch*, and of (2) *Arch. (Angelica, Linneé) atropurpurea*, *Hoffmann*, s. *Ang. triquinata*, *Michaux*.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—These plants attain a height of 6 feet (1.8 M.). The former is indigenous to Northern Europe, and the latter to North America, from Pennsylvania northward. The European angelica-root is solely obtained from plants cultivated in Germany, which differ in some respects from the wild species named, of which they are regarded by some botanists as a variety merely, and by others as a distinct species, *Archan. (Angelica, Miller) sativa*, *Fries*.

Description.—European or garden angelica-root consists of a short, thick root-stock, which is closely annulated above, and below abruptly divided into a large number of nearly simple branches, which are about $\frac{1}{4}$ inch (6 Mm.) thick and 6 inches (15 Cm.) long, longitudinally wrinkled, of a grayish-brown color externally, yellowish inside, with a spongy, radiated medullum and numerous shining resin-cells in the thick bark. It has a strong aromatic odor and a sweetish, pungently aromatic, and bitter taste, and breaks with a smooth somewhat waxy fracture.

American angelica-root is similar, but smaller, has a longer main root, few branches, a lighter color, fewer resin-dots in the bark, and is less strongly aromatic. The very similar but rather smaller root of *Archan. (Angelica, Michaux) hirsuta*, *Torrey and Gray*, which grows southward to Florida, is not unfrequently collected with it.

The root of the European *Ang. sylvestris*, *Linneé*, is light gray-yellow, internally white, and more woody.

All the above roots are readily attacked by insects.

Constituents.—Garden angelica contains about $\frac{1}{2}$ per cent. of yellowish volatile oil, a white waxy matter crystallizing from hot alcohol in wart-like masses; *angelicin*, which is a somewhat acid resin, soluble in alkalis and crystallizing from alcohol in colorless needles; volatile angelic acid; an amorphous bitter principle; some tannin, pectin, and other common principles (*Buchner*, 1842). The volatile oil was examined by *F. Beilstein* and *E. Wiegand* (1882), who, by fractional distillation and rectification over sodium, obtained three terpenes, of which one distilled at 158° C. (316.4° F.), the second near 175° C. (347° F.), and the third near 250° C. (482° F.). The first one is present in largest quantity; the second yields a crystallizable hydrochloride having the properties of the so-called artificial camphor, and melting at 127° C. (260.6° F.). *Naudin* (1883) showed that by distillation *in vacuo* a hydrocarbon of a peppery odor and the boiling-point 166° C. is obtained, and that at 160° C. (320° F.) it becomes thick and polymerized; the volatile oil of the fruit, examined in 1881, boils at 175° C. (347° F.), but becomes thick already at 100° C. (212° F.); these hydrocarbons have been named *terchangene*. The composition of the American roots is probably similar.

Angelic acid, $C_5H_8O_2$, crystallizes in colorless prisms, melts at 45° C. (113° F.), boils at 190° C. (374° F.), has a peculiar aromatic odor and a strongly acid taste, and when melted with potassa yields propionic and acetic acids.

Medical Action and Uses.—Angelica is a tonic, stimulant, and diaphoretic, and in large doses and in warm infusion may act as an emetic or a diaphoretic. It was formerly employed in the treatment of *typhoid* conditions to meet the same indications for which *serpentaria* and *valerian* are now generally administered. It appears to have been beneficial in *chronic bronchitis* under conditions similar to those in which *senega* is recommended. It has also been used in *chronic rheumatism* and *gout* and in *intermittent fever*. Angelica-root may be given in powder in doses of from 10 to 30 grains (Gm. 0.60–2.00), or an infusion made with an ounce (Gm. 32) of the root to a pint of water or white wine may be used in the dose of 1 or 2 teaspoonfuls. Externally, it is sometimes applied as a decoction to foment painful parts.

ANGUSTURA.—ANGUSTURA-BARK.

Cusparia cortex, Br.; *Cortex angustura*.—*Angusture*, Fr.; *Angustura-Rinde*, G.

The bark of *Galipea Cusparia*, *St. Hilaire*, s. *Gal. officinalis*, *Hancock*, s. *Gal. febrifuga*, *Baillon*, s. *Cusparia febrifuga*, *Humboldt*, s. *Bonplandia trifoliata*, *Willdenow*. Bentley and Trimen, *Med. Plants*, 43.

Nat. Ord.—Rutaceæ, *Cuspariæ*.

Origin.—The tree attains a height of 20 feet (6 M.), and is found abundantly in the mountains near the Orinoko River.

Description.—The bark is met with in commerce in flat or curved pieces, usually between 1 and 3 inches (about 5 Cm.) in length, rarely longer, about 1 to 1½ inches (25–38 Mm.) wide, and $\frac{1}{16}$ to $\frac{1}{8}$ inch (1.5–3 Mm.)

FIG. 25.

Angustura-bark: transverse section, magnified 10 diameters.

thick. Its color is reddish-brown, the inner surface smooth and lighter than the outer surface, which is uneven, and, if carefully preserved, covered with an ochrey-gray, scurfy, and friable cork. It breaks readily with a smooth, somewhat granular fracture, which is of a reddish-brown color, resinous in appearance, and displays to the naked eye numerous white, glistening striæ of crystals of calcium oxalate. The latter are more plainly visible with a lens, whereby also the radiating medullary rays and bast-

wedges are revealed. The odor of the bark is aromatic, not agreeable; its taste is aromatic and bitter.

Substitutions.—The so-called false angustura-bark obtained from *Strychnos Nux vomica*, *Linne*, was found in Europe, early in the present century, mixed with the former, to which it bears no resemblance. The trunk-bark is of an irregular shape, rather thick and hard, externally gray, with bright rust-colored patches of cork, and white warts; the inner surface brown; the fracture smooth and destitute of white striæ; the branch-bark is more or less quilled, externally gray, with whitish warts. It has a bitter taste, and contains strychnine and brucine.

Another substitution appears to be frequently met with in France, and has also been noticed in this country (*Amer. Jour. Pharm.*, 1874, pp. 50, 414). This bark, now sometimes called *Brazilian angustura*, comes from Brazil, from *Esenbeckia* (*Evodia*, *St. Hilaire*) *febrifuga*, *Martius*, and consists of dark-brown inner layers, covered with patches of a soft, brownish-gray cork, which is of a pale-orange rust-brown within: it breaks with a short fibrous fracture, is without the white striæ, and has a purely bitter not aromatic taste. Copalchi, guaiacum, and other more or less bitter barks have likewise been observed as adulterations.

Constituents.—The latest analysis of angustura-bark is by Oberlin and Schlagdenhauffen (1878), who found 9.2 per cent. moisture, .27 fat, wax, and stearic acid, soluble in benzin, .47 fat soluble in alcohol and yellow bitter matter, 3.86 resin, .19 volatile oil, 7.8 ash. The bitter matter contained an alkaloid, *angusturine*, $C_{10}H_{10}NO_{11}$, which melts at 85° C. (185° F.), is crystallizable, and is turned red by pure sulphuric acid and green by the same acid containing nitric acid or other oxidizing agent. The volatile oil, according to Herzog (1858), has the composition $C_{13}H_{21}O$, and boils at 266° C. (511° F.). *Cusparia* was obtained by Saladin (1833) by spontaneously evaporating the tincture prepared with strong alcohol. It crystallizes in the cold in needles and tetrahedrons, fuses at a moderate heat, is inflammable, insoluble in ether and volatile oils, soluble in 100 parts of boiling water, but readily soluble in alcohol; it is neutral in behavior and has a bitter taste. Herzog was unable to obtain it. Tannin is not present, but the infusion yields a red-brown precipitate with ferric chloride and several other metallic salts.

The Brazilian angustura-bark contains the alkaloid *erodine* or *esenbeckine*, $C_6H_5NO_6$, which is colored yellowish-green by sulphuric acid (Oberlin and Schlagdenhauffen).

Off. Prep.—*Infusum cuspariæ*, Br.

Medical Action and Uses.—Angustura has a tonic operation without astringency, and a slightly stimulating action. It was at one time supposed to be a valuable antiperiodic, but experience has proved it to have no more claim to this virtue than the simple bitters. It is probably of more use in the *typhoid state* of fevers and inflammations, and

especially in that of tropical *dysentery*, in which its highest reputation has been gained. In ordinary cases of atonic *dyspepsia*, and especially in those in which flatulence predominates, it has been found of service. But it has no special superiority over numerous other tonic and aromatic stimulants which can be more readily procured. The dose of angustura in powder is from 10 to 30 grains (Gm. 0.60–2.00). An infusion may be made by percolation, containing half a troyounce of the bark in a pint of water. *Dose*, 1 or 2 fluidounces (Gm. 32–64).

ANILINA.—ANILINE.

Amidobenzol, *Phenylamine*, E.; *Aniline*, Fr.; *Anilin*, G.

Formula C_6H_7N or $C_6H_5H_2N$. Molecular weight 93.

Origin.—Aniline was discovered by Unverdorben (1826) among the products of the dry distillation of indigo, and was found by Runge (1833) in the heavy oil of coal-tar. Zinin (1842) introduced the method of preparing it from nitrobenzol by the action of sulphuretted hydrogen in the presence of alcohol and ammonia, and A. W. Hofmann (1845) by nascent hydrogen from the action of dilute sulphuric acid upon zinc. The name *aniline* (from *anil*, the Portuguese name for indigo) was proposed by Fritzsche (1841). Unverdorben had called it *crystalline*, and Runge *kyanol* on account of the deep violet-blue color which it gives with chlorinated lime. The identity of these bodies was proven by Erdmann and Hofmann. Aniline has also been named *benzidium* and *phen-amid*.

Preparation.—Aniline is prepared from nitrobenzol by the reducing action of nascent hydrogen, by digesting with a mixture of iron filings and acetic acid, as suggested by Béchamp, in which case the deoxidizing action of ferrous acetate, $Fe(C_2H_3O_2)_2$, first produced, materially assists the change. Nitrobenzol is thereby converted into aniline and water; $C_6H_5(NO_2) + 3H_2$ yields $C_6H_7N + 2H_2O$. The acetic acid has been replaced, by Brimmeyr, by hydrochloric acid. When, after several days, the reaction is completed, milk of lime is added and the aniline is distilled off, the receiver being changed toward the close of the distillation; the temperature then rises, and a red oil, *azobenzid*, $C_{12}H_{10}O_2$, passes over, which congeals to a crystalline mass. The separation of aniline from the heavy oil of coal-tar is effected by a complicated process depending upon its solubility in hydrochloric acid, the insolubility of this compound in ether, the liberation of the bases by an alkali, and their separation from each other by fractional distillation.

Properties.—Aniline is a colorless, limpid, oily, inflammable liquid of a peculiar wine-like odor and burning aromatic taste. It has the spec. grav. 1.0245 at 15° C. (59° F.), congeals at a low temperature, melts at 8° C. (17.6° F.), boils at 184.5° C. (364.1° F.), acquires in contact with air a yellow and brown color, is sparingly soluble in cold water and in all proportions of wood-spirit, alcohol, ether, aldehyd, acetone, and fixed and volatile oils. It dissolves phosphorus, camphor, several resins, and by the aid of heat much sulphur; coagulates albumen; precipitates the salts of iron, zinc, and aluminium; and unites with acids to form salts, which are mostly crystallizable, readily soluble in water, inodorous and colorless, but acquire a red color in contact with the air; alkalies decompose them, with the separation of aniline. Commercial pure aniline usually contains about 1 per cent. of toluidine; other grades contain more of this base.

Toluidine or *amidotoluol*, C_7H_9N or $C_7H_7H_2N$, exists in three modifications, of which two are present in the product of the above process. *Paratoluidine* forms colorless tabular crystals, melts at 45° C. (113° F.), and boils at 198° C. (288.4° F.). *Orthotoluidine* or *pseudotoluidine* is a colorless liquid of the same density as water at 15° C. (59° F.), boiling at 199.5° C. (390.2° F.), and not solidifying at –20° C. (–4° F.).

Toluidine gives a reddish color with chlorinated lime, but aniline is characterized by the production of a violet color with the same reagent—a reaction which has led to its application in the production of *coal-tar dyes*, the more important of which are the following:

ANILINE-PURPLE, or *mauve*, is obtained by acting upon aniline with sulphuric acid and potassium bichromate or other oxidizing agents, whereby the alkaloid *mauveine*, $C_{26}H_{24}N_4$, is produced.

SAFRANINE, $C_{21}H_{20}O_4$, is a red compound obtained from aniline containing toluidine, by treatment with nitrous and arsenic acid.

ANILINE-RED, or *magenta*, is formed by heating a mixture of aniline and toluidine with corrosive sublimate or arsenic acid, and is a salt of *rosaniline*, $C_{20}H_{19}N_3$, or of *para-rosaniline*, $C_{19}H_{17}O_3$, the alkaloids being colorless. *Roseine*, *fuchsine*, and *azaleine* are the

acetate, hydrochloride, and nitrate of the same base. If obtained by the action of arsenic acid the dyes usually contain arsenic. To obtain the dyes free from arsenic the oxidation is now often effected by nitrobenzol or nitrotoluol.

ANILINE-YELLOW, or *chrysaniline*, $C_{20}H_{17}N_3$, is a yellow secondary product of the preceding process; its hydrochloride has a scarlet color, and its nitrate is ruby-red and very sparingly soluble in water.

ANILINE-BLUE is a salt of *triphenyl-rosaniline*, $C_{29}H_{16}(C_6H_5)_3N_3$, obtained by boiling a salt of rosaniline with aniline, and by treatment with iodide of methyl, ethyl, and similar compounds a large variety of blue, violet, and green (*iodine-green*, *methyl-green*, etc.) dyes are obtained.

ANILINE-BLACK, or *jetoline*, a salt of $C_{12}H_{10}N_2$, is very dark-green, and is obtained by the slow oxidation of aniline. *Nigrosine*, $C_{30}H_{29}O_3HCl$, is a similar compound of a dark-blue tint.

The aniline colors are largely employed in dyeing, and are used in the preparation of *colored inks*, which consist of aqueous solutions of the dyes, to which a small quantity of gum-arabic may be added. *Ink for stamping* is made by dissolving 5 parts of the dye in 75 parts of hot water, and adding 1 part of syrup and 2 parts of glycerin. On exposure to light all aniline dyes fade more or less rapidly.

Most of the aniline dyes used in the United States are imported from Europe, the importation having increased from 210,500 pounds in 1877 to 1,103,864 pounds in 1882.

Physiological Action and Medical Uses.—A substance of so little apparent value as a medicine does not here require an extended consideration. It is well, however, to be acquainted with its physiological effects, since many cases of poisoning have occurred from its use. In experiments upon animals it does not appear to act as a powerful local irritant, although in large doses it excites vomiting. Its special action seems to be upon the spinal marrow, for it causes staggering and more or less loss of muscular power and of sensibility in the hinder limbs of quadrupeds, with tonic and clonic spasms affecting all the muscles or only some particular muscles or portions of them. The heart-pulse and the respiration are quickened, and death occurs during convulsion or afterward in resolution. In some experiments death by coma took place. The lethal dose for rabbits is from 15 to 20 grains, and for dogs about 80 grains. Aniline is recognized in the blood and in the urine by its characteristic smell. After death the lungs are found congested and the heart is distended with blood, which there and everywhere else is dark and uncoagulated. The poison is discoverable in the blood and the principal solid organs.

Workmen exposed to the vapors evolved in the manufacture of aniline acquire a cyanotic hue of the face, lips, and mouth, and suffer from giddiness, headache, chilliness, weakness of the lower limbs, and sometimes epileptiform convulsions. They are subject also to bronchial irritation, nausea, constipation, diarrhoea, and cutaneous eruptions. In one case a lad of sixteen employed in scrubbing out an aniline-vat was seized with giddiness and insensibility; the skin was cold, the pulse slow and thready, the breathing laborious. The cyanotic color of his skin and mouth gave him the appearance of a person in the last stage of cholera. The graver symptoms were promptly dissipated, but the blueness had not disappeared on the following day. In the case of a man who swallowed a mouthful of a concentrated solution of "magenta red" the cyanotic symptoms mentioned were present in a high degree; the pulse was thready and frequent (120–140); the inspirations shallow, 30 in a minute; muscular tremor and twitching pervaded the body; the head ached and there was some drowsiness, but the mind was otherwise clear; the patient was restless, and his breathing oppressed as if by a weight. Vomiting was provoked by an emetic, and on the third day he had entirely recovered. The skin continued bluish for more than 48 hours. In a later case no less than 4 ounces were swallowed of a mixture of aniline and toluidine. Nearly 2 hours later the patient felt dull and sluggish and had headache. After vomiting produced by warm water he fell into coma, with the characteristic color of the skin, trismus, and general coldness. Clonic convulsions followed, the pupils were dilated and nearly insensible, and the urine was dark, and later became albuminous. At the end of 24 hours the face was still slightly cyanosed and the pharynx was insensible to tickling. Feltz and Ritter state that a man who drank about 3 pints of wine containing 7 grains of fuchsine soon felt his lips itch, while his ears grew red and his gums were swollen. Afterward, in the course of 12 days, he drank daily about a quart of wine colored with fuchsine. On the last day he suffered from colic and diarrhoea. Dogs that had been given by the mouth or by venous injection large doses of this preparation had albuminuria, and their kidneys were

granular (*Boston Med. and Surg. Jour.*, Sept. 1876, p. 378). Recovery took place in 5 or 6 days (Merklen, *Med. Press and Circular*, 1880, p. 498). Stockings, cravats, gloves, etc. dyed with aniline have occasioned eczematous eruptions upon the skin in contact with them, and patients affected with psoriasis have been poisoned by the application of bandages wet with a solution of muriate of aniline.

Medical Action and Uses.—Aniline has been used in *chorea*. Six inveterate cases are reported to have been speedily cured by this agent in doses of 1 or 2 grains three times a day (Turnbull); while in another group of five cases, in which aniline was given persistently until the doses reached 6 or 7 grains (Gm. 0.40–0.50) three times a day, not the slightest impression was made upon the symptoms (Fraser, etc.). It has also been administered in *epilepsy* without apparent advantage. In 1876, Bergeron and Clouet claimed that the use of fuchsine to color wines was innocuous, and that employed as a medicine it caused the disappearance of albumen from the urine while increasing the proportion of phosphates in this secretion (*Gaz. hebdomadaire*, June 23, 1876). Divet observed that it removed albuminuria without regard to its cause (*Bull. de therap.*, xcviii. 89). Bouehut found it an efficient remedy for scarlatinous dropsy, and not productive of injury (*Practitioner*, xxiii. 203). Similar results were obtained by Sawyer in England (*Practitioner*, xxvi. 41) and De Renzi in Genoa (*Virchow's Archiv*, lxxx. 510). It seems, however, that it has only been conspicuously useful in tubular nephritis, and Dieulafoy denies that it diminishes renal dropsy or its attendant thoracic and pulmonary symptoms (*Bull. de therap.*, xcvii. 478). It appears, therefore, that neither the conditions nor the nature of its influence are at present understood. The daily portion of fuchsine has varied between $1\frac{1}{2}$ and 3 grains (Gm. 0.10–0.20), given in divided doses, and it is said that it may be prescribed to the extent of from 3 to 5 grains without causing nausea.

ANISUM, U. S.—ANISE.

Fructus Anisi, P. G.; *Fructus (Semen) Anisi vulgaris*.—*Anised*, E.; *Anis*, *Anis vert*, Fr.; *Anis*, G.

The fruit of *Pimpinella Anisum*, *Limé*, s. *Anisum vulgare*. *Moench*. Bentley and Trimen, *Med. Plants*, 122.

Nat. Ord.—Umbelliferæ, Orthospermæ.

Origin.—The plant is an annual which is indigenous to the eastern portion of the basin of the Mediterranean, and extensively cultivated in Southern and Central Europe, and occasionally in this country. It grows to about 1 foot (30 Cm.) in height, has the radical leaves roundish-cordate, lobed, and serrate, the stem leaves pinnate with lanceolate lobes, and the upper ones trifid or undivided and linear. The flowers are small and white, in numerous small and long-stalked umbels.

Description.—The fruit is about $\frac{1}{8}$ to $\frac{1}{4}$ inch (4–5 Mm.) long, ovate, tapering above toward the thick stylopode, somewhat compressed at the sides, of a grayish or greenish-gray color, and covered with short appressed hairs. The two mericarps are usually united. Each has five light-brownish filiform ridges, and from 12 to 20 oil-tubes situated on the flat commissure and in the furrows. The fruit has an agreeable aromatic odor and a sweet spicy taste. The importation of anise and star-anise in 1877 was 93,485 pounds, and 367,186 pounds in 1881.

Impurities.—Anise of commerce is not unfrequently mixed with earthy matters resembling the fruit in color. This adulteration is readily detected and the amount thereof determined, according to Hager, by agitating a known weight of anise for a short time with a saturated solution of table-salt; the anise will rise to the surface of the liquid, and after rapidly washing with water and drying is again weighed; earthy matter and sand will subside. Accidental admixtures of *conium-fruit* have been repeatedly reported. This is easily distinguished from anise by the mericarps, when ripe, being separate, smooth, grooved upon the face, with the ribs prominent and crenate, and by being destitute of oil-cells.

Constituents.—The fruit contains, according to Brandes and Reimann, 3 per cent. of volatile oil, 3.38 per cent. of fixed oil, some gum, sugar, resin, malates, phosphates, and other salts. The volatile oil represents the medical properties of the fruit. (See *OLEUM ANISI*.)

Pharmaceutical Uses.—Anise is used for preparing *Oleum anisi* and *Aqua anisi*.

FIG. 26.

Anisum: Fruit and longitudinal section, magnified 3 diameters; transverse section, magnified 8 diameters.

Off. Prep.—Tinct. Rhei dulcis, U. S.

Medical Action and Uses.—Although it imparts a peculiar taste to the milk of nurses, it probably does not augment the secretion (Dolan). Anise is an aromatic stimulant and carminative; its oil and infusion are habitually employed to relieve *flatulent colic*, and the seeds enter into the composition of many culinary products as a condiment which tends to render them less indigestible. It has been imagined to have some special influence upon the *bronchial tubes*, modifying their secretions and promoting expectoration. But all volatile oils and resins are exhaled by the bronchia, and all have more or less repute as stimulant expectorants. In *infantile catarrh*, when the acute stage has passed, infusion of anise may be given with advantage. It may be made with 2 or 3 drachms (Gm. 8–12) of the bruised seeds in half a pint of boiling water, and given in teaspoonful doses to infants at the breast. The dose of bruised anise is from 10 to 20 grains (Gm. 0.60–1.20).

ANTHEMIS, U. S.—ANTHEMIS.

Anthemidis flores, Br.; *Flores Chamomilla romana*.—*Chamomile-flowers*, Roman or English chamomile, E.; *Camomille romaine*, Fr.; *Römische Kamille*, G.

FIG. 27.

The flower-heads of *Anthemis* (*Chamomilla*, *Godr.*) *nobilis*, *Linné*, collected from cultivated plants. Bentley and Trimen, *Med. Plants*, 154.

Nat. Ord.—Compositæ, Senecionideæ.

Origin.—A low perennial plant indigenous to Southern and Western Europe as far north as England, and cultivated in Germany, Great Britain, France, and Belgium. The small oblique rhizome produces numerous prostrate or ascending and radiating stems, with alternate sessile grayish-green leaves, which are hairy and twice or thrice pinnately divided into acute linear segments. The flower-heads terminate the branches, and appear from June to September. *Anthemis*-flowers have been dismissed from the German Pharmacopœia.

Description.—The flower-heads of the wild plant, which have a single row of white ligulate ray-florets and numerous yellow

tubular disk-florets, are not met with in commerce. In the cultivated plant the tubular florets are more or less changed into white ligulate florets, and therefore the heads have either a smaller yellow centre or are entirely white. The heads are about $\frac{3}{4}$ inch (2 Cm.) broad, and consist of an involucre composed of numerous imbricated oblong ovate scales with a scarios margin, of a solid convex finally conical receptacle with narrow concave chaff, and of numerous white strap-shaped and three-toothed florets, which are pistillate. The yellow disk-florets, if present, are tubular, five-toothed, and hermaphrodite, with the two branches of the style projecting. The tapering achene is destitute of a pappus. Since the oil-glands are found mainly on the tubular portion of the florets, the so-called *single chamomile*, with one or a few rows of ray-florets, appears to be better adapted for medicinal use, and has a stronger and more agreeable odor.

Adulterations.—The flower-heads of several Compositæ, like *Anthemis arvensis*, *Linné*, *Maruta Cotula*, *De Candolle*, *Matricaria Chamomilla*, *Linné*, *Pyrethrum Parthenium*, *Linné*, and *Achillea Ptarmica*, *Linné*, have been named as occasional adulterations, but they are much smaller than Roman chamomile. The first-named three species, not being cultivated, have the heads always with a single row of ray-florets, while the last two are frequently double in cultivation. Of these, the feverfew (*Pyrethrum*) has a flat or merely convex and nearly naked receptacle, and the *Achillea* flowers have shorter and rounded rays, are inodorous, and of an acrid taste.

Constituents.—According to J. P. Wyss (1833), chamomile-flowers contain volatile oil (see *OLEUM ANTHEMIDIS*), traces of tannin, 5.25 per cent. resin, 1.50 per cent. wax, albumen, gum, bitter principle, fixed oil, chlorophyll, extractive, and salts. From the investigations of Camboulises (1871) it seems probable that the bitter taste is due to

anthemic acid (see *MATRICARIA*); fat, grape-sugar, and 6 per cent. of ash were found in the flowers. The bitter principle is soluble in water and alcohol.

Pharmaceutical Uses.—For preparing *Oleum anthemidis*, *Extract. anthemidis*, and *Infusum anthemidis*, *Br.*

OLEUM ANTHEMIDIS INFUSUM, Oleol of chamomile, *E.*; Huile de camomille, *Fr.*; Gekochtes Römisch-Kamillenöl, *G.*—Digest for 2 hours chamomile-flowers 10 parts in olive oil 100 parts; express and filter.—*F. Cod.*

Physiological Action.—Chamomile is stimulant and tonic. The former property is due to its essential oil, the latter to its bitter principle. In substance or strong infusion it occasions a sense of warmth in the stomach; it expels flatus, improves digestion, does not constipate, and, like other aromatic stimulants, is reputed to possess emmenagogue virtues. In large doses it occasions nausea, vomiting, diarrhœa, pain, and fulness of the head, and sometimes a degree of somnolent intoxication. In medicinal doses the infusion is tonic if cold, but emetic if warm.

Medical Uses.—Chamomile is commonly used as a mild stimulant tonic to improve the digestion during convalescence from acute diseases and in many states of general debility. It is particularly indicated when the gastric digestion is laborious and accompanied with flatulence, and also when the latter stage of the process is attended with colic. It is an excellent preventive remedy for periodical sick headache, and its warm infusion is a salutary emetic during the attack. It is reputed also to be *emmenagogue*, to cure *neuralgia*, and to diminish chronic *suppuration*. Evidently, it exerts these powers indirectly and only by its power of improving the nutrition of the whole system. In the same way, probably, it sometimes cures *intermittent fever*. Many bitter tonics have a similar operation, but cinchona alone exhibits a direct curative control over periodical fevers. These remarks apply only to their use as tonics; chamomile and its associate bitters often cure mild intermittents when administered in the form of a hot infusion immediately before the paroxysm. This is a physiological mode of cure, and may be practised with the aid of whatever will equally well excite copious diaphoresis. In forms of malarial fever distinguished by *biliary derangement* warm chamomile tea is often used to produce both vomiting and diaphoresis, and thereby not only to moderate the general severity of the paroxysm, but also to lessen hepatic congestion and the evils which ensue thereon. As an emetic, chamomile is peculiarly appropriate whenever it is desired to empty the stomach without depressing the system, and hence in those numerous cases of *crapulous indigestion* occurring in coarse feeders and in drunkards. It often will put an end to an attack of *delirium tremens* in the forming stage. Subsequently, nothing excels a cold infusion of chamomile in repairing the exhausted condition of the digestive organs.

Externally, fomentations made with chamomile-flowers saturated with hot water or with hot vinegar and water form a most soothing application for *local pains*, whether neuralgic or congestive, in intestinal and uterine *colic*, *toothache*, *carache*, *abscess*, *sprains*, etc. It is believed by high authorities that the odor of chamomile is destructive of the *itch-insect*, the *gnat*, etc. Oil of chamomile has been applied to painful *rheumatic* parts and to the abdomen in *flatulent colic*.

Chamomile is never prescribed in substance except as a masticatory, and in this manner it is often useful in slight dyspeptic disorders. The extract (*Br. Ph.*) is a good simple bitter tonic in the dose of from 3 to 10 grains (*Gm.* 0.20–0.60). A fluid extract is prepared, a fluidrachm of which represents 30 grains of chamomile. The oil is sometimes prescribed internally in doses of 5 or 6 drops upon sugar, in ether, in Hoffmann's anodyne, or in pills made with crumb of bread. An infusion is made with half a troyounce of chamomile to a pint of boiling water. When cold it is used as a tonic in doses of 1 or 2 fluidounces (*Gm.* 30–60). When warm it acts as an emetic if freely drunken.

ANTIARIS.—UPAS ANTIAR.

Upas antiar, *Fr.*, *G.*

A gum-resinous exudation of *Antiaris toxicaria*, *Leschenault*.

Nat. Ord.—*Urticacæ*, *Artocarpeæ*.

Origin.—The upas tree is one of the largest trees of the forests of Java and of some of the neighboring islands. When wounded it yields a milk-white or yellowish exudation, which on exposure turns brownish, and constitutes the principal ingredient of the *Upas antiar*, or Javanese arrow-poison.

Description.—*Upas antiar* is reddish-brown, of a waxy consistence, and has an

extremely bitter and at the same time acid taste. Triturated with water, it yields an emulsion. It is partly soluble in alcohol and ether.

Constituents.—It contains gum, sugar, albumen, wax, resin, and *antiarin*, the poisonous principle discovered by Pelletier and Caventou (1824). The latter is obtained by exhausting the alcoholic extract with boiling water. Malder obtained from the dry juice 3.5 per cent. of antiarin, the composition of which is $C_{11}H_{20}O_5$. It crystallizes from water in silvery scales containing 11.86 per cent. ($2H_2O$) of water, and is soluble in 70 parts of alcohol, very slightly in ether, more freely in dilute acids and alkalis. The resin is readily soluble in ether, sparingly in cold alcohol, and is not poisonous.

Physiological Action.—Under the name “upas,” which in the Malay language signifies poison, or, specifically, arrow-poison, several quite different products are included. Upas Tieuté contains strychnia, and the symptoms it occasions are more or less distinctly tetanic, but Upas antiaris and its active principle, antiarin, produce very different effects. However introduced into the system, it impairs or suspends voluntary movements without causing convulsions. It is a paralyzing poison to the heart as well as the voluntary muscles, and appears to act directly upon these organs and upon the great nervous trunks, but not upon the brain or spinal marrow. A specimen of arrow-poison has been found to contain both a convulsing and a paralyzing agent, which could be separated and made to display their respective effects.

We are unacquainted with any instances of the therapeutical use of this product, but the remarkable analogy of its operation with that of physostigma would seem to indicate its application to similar conditions.

ANTIMONII ET POTASSII TARTRAS, U. S.—TARTRATE OF ANTIMONY AND POTASSIUM.

Antimonium tartaratum, Antimonii potassio-tartras, Antimonium tartarisatum, Br.; Tartarus stibiatus, Tartarus emeticus, Sibiokali tartaricum, P. G.—Tartarated antimony, Tartar emetic, E.; Tartrate de potasse et d'antimoine, Émétique, Tartre stibié, Fr.; Brechweinstein, G.

Formula $2(KSbOC_4H_4O_6) \cdot H_2O$. Molecular weight 664.

Origin.—A process for the preparation of tartar emetic from cream of tartar and crocus of antimony was first published in 1631 by Adrian van Mynsicht. (Glauber (1648) used flowers of antimony or antimonial glass. At present the salt is generally prepared with oxychloride or with pure oxide of antimony. Both the British and German Pharmacopœias recognize two synonyms besides the official title.

Preparation.—Take of Oxide of Antimony 5 ounces; Acid Tartrate of Potash in fine powder 6 ounces; Distilled Water 2 pints. Mix the oxide of antimony and acid tartrate of potash with sufficient water to form a paste and set aside for 24 hours. Then add the remainder of the water and boil for a quarter of an hour, stirring frequently. Filter and set aside the clear filtrate to crystallize. Pour off the mother-liquor, evaporate to one-third, and set aside, that more crystals may form. Dry the crystals on filtering-paper at the temperature of the air.—*Br.*

The process formerly recognized by the U. S. Pharmacopœia consisted in boiling for 1 hour 18 fluidounces of water containing a mixture of 2 troyounces of oxide of antimony and $2\frac{1}{2}$ troyounces of acid tartrate of potassium, water being added from time to time to supply the loss by evaporation. This long-continued application of heat is apt to produce a change whereby the liquid becomes colored and a portion of the salt is converted into an uncrystallizable compound; the mother-liquor from the first crystallization yields, on further evaporation, crystals which are colored and require to be recrystallized. By the British process heat is avoided, except for a much shorter time, the combination being effected at the ordinary temperature; or digestion at a gentle heat may be resorted to with little danger of inducing the changes alluded to. The compounds are made to react upon each other in the presence of a little water, a slight excess of antimonious oxide being used; and the subsequent boiling with a larger quantity of water mainly aims at bringing the tartar emetic already formed into solution, so that it may be freed by filtration from the excess of oxide used, and obtained in crystals. It is of importance that the antimonious oxide should be free from oxychloride, otherwise the mother-liquor will become acid, and more or less of the salt will be lost by refusing to crystallize. The acid potassium tartrate should be free from calcium tartrate, which would contaminate the crystals of tartar emetic, necessitating their recrystallization, and thus occasioning loss.

Other processes have been recommended, and are perhaps followed by some manufac-

turers: they agree in this, that an impure oxide of antimony, which may be obtained in various ways, is used. While the trouble of its purification is thus avoided, a subsequent loss cannot be prevented, as explained above. Operating on a large scale, such a course is probably the cheapest, but for the pharmacist the use of pure materials is by far more advantageous, since with proper and careful manipulation the entire solution may be made to crystallize.

Properties.—Tartrate of antimony and potassium produces colorless transparent crystals, which have the form of a rhombic octahedron, become white and opaque on exposure to the air, and have a sweetish afterward disagreeable strongly metallic taste. In commerce it is usually seen in the form of a white finely-granular powder. Heated to 108° C. (226.4° F.), the salt loses its water of crystallization; at 200° C. (392° F.) it parts with more water, and is converted into metatartrate; at a higher heat it decomposes, becomes brown and black, giving off empyreumatic products having the odor of burning sugar, and finally leaves a black or gray residue having an alkaline reaction. According to Brandes, 1 part of the salt

Dissolves in	19.0,	12.6,	8.2,	7.1,	5.5,	4.8,	3.2,	3.0,	2.8	parts of water
at	8.7°,	21°,	31°,	37.5°,	50°,	62.5°,	75°,	87.5°,	100°	C.

The aqueous solution is precipitated on the addition of alcohol in the form of a crystalline powder: in this manner a pure powder of tartar emetic is readily and most advantageously obtained for pharmaceutical purposes. The solution yields with hydrochloric and other mineral acids a white precipitate of an oxy-salt of antimony, which is soluble in hydrochloric acid, and does not occur if tartaric acid has been previously added to the solution. The aqueous solution, even if largely diluted, at once becomes turbid on the addition of a little potassium carbonate. Hydrosulphuric acid causes an orange-red precipitate, which, when obtained from 20 grains of the salt after washing and drying at 100° C. (212° F.), weighs 9.91 grains. A solution of tartar emetic which is not too dilute produces a flocculent precipitate on the addition of infusion of galls; an excess of the latter redissolves the precipitate. The salts of most metals and earths, being precipitated by normal tartrates, are incompatible with tartar emetic; also the alkalies, tannin, and tinctures containing tannin.

Tests.—Chlorides and sulphates, if present, are detected in the solution, previously acidulated with acetic acid, by nitrate of silver and chloride of barium, calcium by ammonium oxalate, and copper, iron, and other metals by ferrocyanide of potassium. "A 1 per cent. solution of the salt should not be clouded by the addition of a few drops of the reagents named."—*U. S.* Arsenic may be detected by carefully heating about 20 or 30 grains of the salt until a black residue remains; on gradually increasing the temperature to redness a garlic-like odor will be evolved. More delicate tests are the following: "If 1 Gm. of the salt and some pieces of aluminium wire be added to strong solution of soda (sp. gr. about 1.260) contained in a long test-tube, a gas is given off which should not impart any color to filter-paper wet with test solution of nitrate of silver and held over the mouth of the test-tube (absence of more than traces of arsenic)."—*U. S.* "If .5 Gm. of the salt be dissolved in 10 Gm. of hydrochloric acid without heat, and 2 drops of freshly-saturated solution of sulphuretted hydrogen added, neither a yellow color nor a yellow precipitate should be produced within 4 hours."—*P. G.* The impurity which is likely to be met with in consequence of faulty preparation is cream of tartar, the presence of which cannot be detected by its behavior to test-paper, since the solution of tartar emetic has an acid reaction; but a permanent precipitate will not appear with potassium carbonate until after this impurity has been neutralized. By dissolving 24 grains of the salt in a fluidounce of warm water and cooling the solution to 10° C. (50° F.) it should remain clear. A crystalline deposit will occur if more than 8 per cent. of cream of tartar is present. A more delicate test, which, however, does not indicate the nature of the impurity, consists in preparing the sulphide of antimony from a given weight of the salt, as stated above.

Pharmaceutical Uses and Preparations.—Tartar emetic is a convenient test for distinguishing different kinds of tannin, some of which yield no precipitate with it. It is an ingredient in Syrupus scillæ comp., *U. S.*; Unguentum antimonii tartarati, *Br.*; and Vinum antimonii (antimoniale, *Br.*), *U. S.*

EMPLASTRUM ANTIMONII. *U. S.* 1870; **EMPLASTRUM STIBIATUM** s. **ANTIMONIALE.**—Antimonial plaster, *E.*; Emplâtre (Poix) émétiée, Emplâtre antimonial, *Fr.*; Brechweinstein-Pflaster, *G.*—Take of Tartrate of Antimony and Potassium in fine powder a troyounce; Burgundy Pitch 4 troyounces. Melt the pitch by means of a water-bath and

strain; then add the powder, and stir them well together until the mixture thickens on cooling. The finely-powdered tartar emetic should not be added until the fused mass almost begins to thicken; the addition of 2 or 4 drachms of wax would improve the adhesive qualities of the plaster.

Physiological Action.—*On Animals*: The following conclusions in regard to the action of tartar emetic were reached by Dr. Richardson in 1856, and they remain substantially correct at the present time: "1. Tartar emetic excites the same symptoms in dogs as in man. 2. All the permeable tissues absorb it, and its effects are specifically the same by whatever channel, including the blood, it may enter the system. 3. After absorption it may be detected in the blood, the serum, the urine, and all the organs. 4. It excites marked local effects in any membrane by which it is eliminated, and hence, however introduced into the system, it causes redness of the lining membrane of the stomach and the symptoms which attend its direct application to that organ. 5. In large doses it produces vomiting and purging and rapid collapse, but small doses long continued may cause death by exhaustion. 6. The immediate cause of death from this agent is, in all cases, failure of the heart's action. 7. The post-mortem lesions produced by it are general congestion, fluidity of the blood, intense vascularity of the greater curvature of the stomach, and in some cases of the rectum and other parts of the intestinal tube, but without ulceration, and a pale-yellow, glairy, mucous secretion. 8. In rapid poisoning by tartar emetic the fatal effect seems due to a direct chemical change in the blood, and an indirect effect therefore upon the heart; while in slow poisoning there is added an interference with the assimilative powers, the result of the lesions excited in the stomach or other parts of the alimentary canal." In this summary there is an apparent incongruity between the statement that death is due to failure of the heart's action and also to a chemical change in the blood. Doubtless both modes concur, but the first is shown by experiment to be a primary effect of the poison, the heart being weakened and its contractions retarded, the respiration and the temperature declining in a like proportion, while paralysis of sensation and motion supervenes. This mode of action accounts for the venous engorgement of the heart, lungs, and abdominal organs found after death. The injection of the gastro-intestinal mucous membrane is due not so much to the primary irritant action of the poison as to the fact, already implied, that it is in great part eliminated by this channel, however it may have been introduced into the body. According to Hoeh (*Inaugural Essay*, Univ. Penna., 1880), antimony is eliminated chiefly by the kidneys. It may be found in the urine 5 minutes after ingestion, and continue to be present for 97 hours. In regard to the mechanism of the action of tartar emetic, Solowitschyk drew from his experiments the following conclusions: In frogs, after slightly stimulating the co-ordinating centres of the medulla oblongata, it paralyzes the spinal reflex functions and the excito-motor nervous apparatus of the heart, but does not lessen the excitability of the motor nerves and voluntary muscles. In mammals it continuously reduces the blood-pressure by dilating the blood-vessels and perhaps by directly depressing the heart, disturbs the functions of the central nervous system, and occasions vomiting and purging by causing a moderate congestion of the blood-vessels of the mucous membrane. In this operation antimony exhibits a complete analogy to the action of arsenic and platinum (*Archiv. f. experiment. Pathol. u. Pharm.*, xii, 438).

On Man: When tartar emetic in strong solution or in an ointment is applied to the skin it produces a pustular eruption almost identical in appearance with that of small-pox, forming scabs and leaving indelible scars. If the skin is very delicate it may ulcerate or slough. The pustulation is less apt to occur in persons of a naturally tough integument and also during high febrile action. Occasionally the constitutional operation of the medicine has been developed by its endermic employment. A solution of tartar emetic has been injected into the veins for the purpose of dislodging foreign bodies from the stomach by vomiting. This effect has also followed its administration by enema.

Taken internally, even in such doses as the $\frac{1}{100}$ th of a grain frequently repeated, it occasions malaise and nausea, with colic and looseness of the bowels, loss of appetite, a pasty state of the mouth, debility and depression, and sometimes a pustular eruption on the skin. When the dose is large enough to excite vomiting it produces a sense of sinking, nausea, copious salivation, violent and prolonged retching, and often liquid stools, coldness of the hands and feet, and a cool perspiration. The matters vomited usually contain bile before the end of the operation. If the salt is given with but little fluid, the evacuations may be confined to vomiting; if the liquid is abundant, there may be copious purging without emesis. The more depressing the operation of the medicine, as indicated by the preceding symptoms, the more frequent and feeble does the pulse become. In the

case of a boy whose brain-membranes were exposed, Dr. Mary Putnam Jacobi observed that in 2½ hours after the administration of a quarter of a grain of tartar emetic, which did not occasion vomiting, the intra-cranial blood-pressure was diminished and the walls of the arteries relaxed. This peculiarity was not noticed under the action of sedative doses of quinine, and was confined to the nauseating dose of tartar emetic. Tartar emetic is eliminated chiefly by the kidneys (Morton).

In poisoning by this substance the symptoms mentioned are greatly intensified. The patient is attacked with pain in the stomach, followed by incessant retching, præcordial cramps and burning heat, distension of the epigastrium, severe colic, watery and frequent stools, dryness of the throat, difficult deglutition, and salivation. The muscles are sometimes rigid, but generally relaxed; the skin pale, cool, and clammy; the pulse feeble and at first infrequent, but subsequently rapid and thready; respiration is slow. The dose required to produce such symptoms cannot be precisely stated. It may be but the fraction of a grain which occasions them with a fatal result. In other instances several drachms of the salt have been taken without fatal consequences. Its continued use generally establishes a tolerance of its operation, as was formerly shown by its employment in the treatment of pneumonia—a method which is now forgotten except as a monument of rashness and folly. The use of this method illustrated the local action of the salt by the inflammation and ulcers which it sometimes produced in the mouth, fauces, œsophagus, and stomach. It is to be noted that after fatal acute poisoning by tartar emetic gastric lesions are not always found—a fact which further illustrates the previous proposition, that it causes death by its action upon the heart and lungs through the nervous system, and not merely by its local operation on the stomach.

Medical Uses.—The idea that fever must be combated by means of agents which directly tend to lessen the frequency and lower the force of the pulse, and which was formerly carried out by venesection and purgation, and more recently by veratrum viride, aconite, and digitalis, was at one period sought to be realized by means of tartar emetic. The palpable mischief wrought by the last-named agent when so employed reached its extreme development when Rasori, an Italian theorist, demonstrated that it was possible to administer 24 grains in as many hours of this salt to a pneumonic patient, and as much as 2 ounces in the course of an attack of *pneumonia*, without occasioning such a mortality as might reasonably have been expected. Indeed, many of the most distinguished clinical observers have recorded their eulogies of this treatment, and if it were to be compared with those alone which approach it in their perturbative effects, it might still maintain the claims which once were made in its behalf. But since it has been demonstrated that the most successful by far of all methods of treating pneumonia is simply to place the patient in the most favorable conditions for the exertion of his natural powers of cure, a discussion of the relative values of different active medications has greatly declined in interest as well as utility. Even in 1882 some indications existed of a desire to return to this obsolete method, which seemed to have been finally condemned and abandoned by the physicians of all countries. But we trust that the number of those who are acquainted with its martyrology will prove sufficient to check this dangerous tendency. The proposed revival did not, indeed, contemplate the use of the original sedative doses, but only the administration of divided doses until vomiting and purging had occurred three or four times. That such a method may be useful in exceptionally robust persons and in the early stages of the disease may be admitted, but its dangers, as well as its needlessness, in all other cases we cannot for a moment doubt.

A confusion produced by ignorance of the essential differences between pseudo-membranous *laryngitis* and spasmodic *laryngitis* led to the use of tartar emetic in the former disease, although clinical observation and analogy are strong against it, for it tends to produce a sudden and extreme prostration, and thereby to lessen the chances of the removal of the false membrane by coughing. On the other hand, the spasmodic affection, which involves also a superficial inflammatory element, is beneficially treated by nauseants and emetics which relieve at once the congestion and the spasm of the larynx and terminate the attack. It is not generally necessary to excite vomiting with this object; nauseant doses of the medicine are usually sufficient. This statement is indirectly illustrated by the usually prompt effect of opiates and revulsives in the same affection. Among inflammatory diseases *acute bronchitis* is most decidedly modified by nauseant doses of this medicine, and even by smaller ones than produce any sensible effect besides an increase of the bronchial secretion and a greater facility of expectoration. Acute articular *rheumatism* was at one time treated by sedative doses of tartar emetic, but the evidence

in its favor, which was originally small, is less than nothing at the present day. It has been said that nauseating and depressing doses of it will sometimes cut short various local inflammations in their forming stage, such as *tonsillitis*, *mammary abscess*, *hernia humoralis*, acute *ophthalmia*, *mumps*, etc. There is very little doubt of the fact, but the uncertainty of action of the medicine and its distressing operation have, for the present at least, rendered its use in these affections quite exceptional. It has been employed in *dropsy* produced by cold (renal dropsy); to arrest mercurial *salivation*; in acute *meningitis*; in *epilepsy*, *chorea*, *mania*, *convulsions*, *mania-à-potu*, etc.; but in none of these diseases does the good it effects outweigh the inconveniences arising from its depressing and exhausting operation. Its power of overcoming *rigidity of the os uteri* during labor has been attested by the highest authorities, but owing to the superior advantages of anæsthetics it is now seldom resorted to. The same remark applies to its use for producing relaxation in *strangulated hernia* and *dislocations*. Locally, it has been applied to excite inflammation and thereby destroy *nævi*, and also to produce the constriction and closure of *varicose veins*. The plaster and the ointment of tartar emetic, which are no longer officinal, were used to pustulate the skin. But the severity of their action and the scars they frequently left behind them have led to their disuse.

Tartar emetic should seldom be administered to the very young or very old or to those who from any cause are feeble. If it produces *poisoning* by being swallowed, the stomach should be emptied as soon as possible by large draughts of tepid water containing or followed by vegetable astringents, such as green tea, galls, tannic acid, etc. Its sedative effects may be moderated by strong coffee, by wine, alcohol, ether, or opium.

The average emetic dose of tartar emetic is 1 grain (Gm. 0.06), or 3 grains (Gm. 0.20) may be dissolved in a fluidounce of water, of which one-half may be administered; if this have no effect, half of the remainder may be given in 15 minutes, and in 15 minutes more the rest. Warm water should be freely administered. As a nauseant sudorific the dose is from a quarter to half a grain (Gm. 0.01–0.03) every hour or more. As a diaphoretic and expectorant from one-twelfth to one-sixth of a grain (Gm. 0.005–0.01) may be given at intervals of from 1 to 3 hours. Pustulation may be produced by means of tartar emetic ointment, by a strong watery solution applied on a compress, or by inoculation of a paste made with the salt and by means of a fine lancet, or by the antimonial plaster (*U. S. P.* 1870). The last is a painful and unmanageable preparation.

ANTIMONII OXIDUM, *U. S., Br.*—OXIDE OF ANTIMONY.

Stibium oxydatum, *Oxydum antimonicum* s. *stibicum*.—*Antimonious oxide*, *E.*; *Oxyde d'antimoine*, *Fr.*; *Antimonoxyd*, *G.*

Formula Sb_2O_3 . Molecular weight 288.

Origin.—Oxide of antimony in an impure form was known to the alchemists of the Middle Ages. The term *flores antimonii* was at first chiefly applied to the product obtained by the burning of the black sulphide, but subsequently to the purer white powder resulting from the burning of metallic antimony in the air. The mineral *valentinite* or *white antimony* consists of this oxide; *antimony ochre* or *cerantite* is antimonious-antimonic oxide.

Preparation.—Take of Solution of Chloride of Antimony 16 fluidounces; Carbonate of Soda 6 ounces; Water 2 gallons; Distilled Water a sufficiency. Pour the antimonial solution into the water, mix thoroughly, let the precipitate settle, remove the supernatant liquid by a siphon, add 1 gallon of distilled water, agitate well, let the precipitate subside, again withdraw the fluid, and repeat the process of affusion of distilled water, agitation, and subsidence. Add now the carbonate of soda, previously dissolved in 2 pints of distilled water, leave them in contact for half an hour, stirring frequently, collect the deposit on a calico filter, and wash with boiling distilled water until the washings cease to give a precipitate with a solution of nitrate of silver acidulated by nitric acid. Lastly, dry the product at a heat not exceeding 100°C . (212°F.).—*Br.*

The process of the *U. S. Pharmacopœia* (1870) was essentially the same as the above, except that directions were also given for preparing a solution of antimonious chloride by digesting black sulphide of antimony 4 parts with hydrochloric acid 18 parts. By this treatment $\text{Sb}_2\text{S}_3 + 6\text{HCl}$ yields 2SbCl_3 , which remains dissolved in an excess of the acid, and $3\text{H}_2\text{S}$, which escapes; the solution contains also ferrous chloride, resulting from the iron usually contained in the black antimony. The subsequent step of adding nitric acid was an unnecessary complication; it will oxidize any sulphuretted hydrogen that may have remained in solution to sulphuric acid, and convert the ferrous into ferric chloride; but the former can be expelled more expeditiously and with less cost by boiling the solution,

and the ferrous chloride will not be precipitated on the addition of water, which will also retain in solution the chlorides of the other metals occasionally present. On adding the solution to water, antimonious oxychloride, or *powder of Algaroth*, is precipitated and obtained of the composition $2\text{Sb}(\text{Cl}_3.5\text{Sb}_2\text{O}_3)$. By washing this with water the chlorine is gradually but not completely removed as hydrochloric acid, a more basic oxychloride remaining. The conversion into the oxide is most readily effected by an alkali or alkaline carbonate, for which purpose ammonia may be used or sodium carbonate, as directed above. In the one case ammonium chloride, in the other case sodium chloride and carbonic acid gas, are formed, antimonious oxide remaining behind in both instances; $2\text{Sb}(\text{Cl}_3.5\text{Sb}_2\text{O}_3) + 3\text{Na}_2\text{CO}_3$ yields $6\text{Sb}_2\text{O}_3 + 6\text{NaCl} + 3\text{CO}_2$. The resulting antimonious oxide must be dried at a not too elevated temperature, to avoid the formation of higher oxides of antimony. A contamination with arsenious acid, resulting from the sulphide of arsenic frequently present in the black antimony, need not be apprehended; the greater part of it will be expelled during the first part of the operation as chloride of arsenic, and what little may be left in the liquid will remain in solution on precipitating with water. The large quantity of noxious gases given off renders it necessary to operate under a hood or to dispose of the gases by consuming them in a furnace.

On heating metallic antimony in a loosely-covered crucible the metal burns at a red heat when in contact with air to antimonious oxide, and this sublimes in glossy, transparent, or white needles, intermixed with octahedrons; this product was formerly distinguished as *flores antimonii* (*flowers of antimony*).

Properties.—Antimonious oxide is a dense white or grayish-white powder, which is very sparingly soluble in water, insoluble in alcohol, ether, and nitric acid, but dissolves readily in hydrochloric or tartaric acid. It is without odor and taste, and when heated in closed vessels turns yellow, and on cooling becomes white again; melts at a dull red heat to a yellowish liquid, which on cooling congeals white and crystalline, and at a full red heat sublimes in crystals, as stated above; slow sublimation gives mainly octahedrons, while rhombic prisms are obtained by rapid heating. But when the oxide is slowly heated in contact with air it is converted into grayish, infusible, and non-volatile tetroxide, or *antimonious-antimonic oxide*, Sb_2O_4 or $\text{Sb}_2\text{O}_3.\text{Sb}_2\text{O}_5$; and on being rapidly heated in the air to dull redness antimonious oxide melts, and on cooling solidifies into a pearl-colored crystalline mass. When heated with soda upon charcoal by means of the blowpipe very brittle metallic globules are obtained. Its solution in hydrochloric acid dropped into water yields a white precipitate, and this is at once changed to orange-red by sulphuretted hydrogen.

Tests.—Oxide of antimony should dissolve completely when boiled with an excess of acid potassium tartrate (earthy impurities, etc.), and its solution in tartaric acid should not be precipitated by nitrate of silver (chlorides), chloride of barium (sulphates), or ferrocyanide of potassium (metals).

Pharmaceutical Uses.—Oxide of antimony is employed in preparing tartar emetic, and is a constituent of Pulv. antimonialis, *U S.*, *Br.*

OTHER OXIDES OF ANTIMONY, more or less pure or combined with sulphide of antimony, were formerly employed in medicine, and are occasionally, though very rarely, called for. When black sulphide of antimony is gradually heated to redness in contact with the air, it is partly oxidized to antimonious antimoniate, $\text{Sb}_2\text{O}_3.\text{Sb}_2\text{O}_5$, and constitutes then an ash-gray powder known as *ciris antimonii* (*antimony ash*). When this is fused with a little black antimony a transparent garnet-red mass known as *citrum antimonii* (*antimonial glass*) is obtained. When a mixture of equal parts of black antimony and potassium nitrate is deflagrated by igniting it in small quantities, it yields *hepar antimonii* (*liver of antimony*), and when this is exhausted with water to remove sulphate and sulphantimoniate of potassium *crocus of antimony* is left behind, which is mainly a mixture of oxide and sulphuret of antimony. *Antimonium diaphoreticum* (*diaphoretic antimony*) is prepared like liver of antimony, except that more (2 parts of) potassium nitrate is used, so that the preparation contains, besides oxide of antimony, antimoniate, sulphate, nitrate, and nitrite of potassium in varying proportions. By washing this with water the residue consists mainly of *antimoniate of potassium*, which is recognized by the French Codex. The other preparations described were formerly employed in medicine.

Medical Action.—The oxide of antimony is rarely used in medicine. It is stated to possess the general properties of antimonial preparations, with a less tendency to excite nausea and vomiting, owing to its inferior solubility. Its *dose* is from 2 to 4 grains (Gm. 0.10–0.20).

ANTIMONII SULPHIDUM, U. S.—SULPHIDE OF ANTIMONY.

Antimonii sulphuretum, U. S. 1870; *Antimonium nigrum*, Br.; *Stibium sulfuratum nigrum*, P. G.; *Antimonium crudum*, *Sulphuretum stibicum*.—Black (crude) antimony, Sulphuret or Trisulphide of Antimony. Antimonious sulphide, E.; Sulfure d'antimoine, Antimoine cru, A. sulfuré, Fr.; Schwefelspiessglanz, Spiessglanz, Schwefelantimon, G.

Formula Sb_2S_3 . Molecular weight 336.

Origin.—It is found native as *stibnite*, gray antimony ore, or black antimony, and associated with galena, iron pyrites, quartz, and heavy spar, in various parts of Europe, Borneo, New Brunswick, Nevada, and in Sevier co., Ark. It was known to the ancients as "stimmi," and was early employed as an external remedy in cutaneous diseases and for darkening the eyebrows and eyelashes. From the infusible ores with which it is associated it is freed by fusion in pots arranged in such a manner that the fused sulphide runs off into earthen vessels, where it cools. It is afterward powdered.

Properties.—Thus purified, it is known in commerce as crude antimony, and contains variable small quantities of iron, and often traces of arsenic, lead, and copper, all in the state of sulphides. From the shape of the pots in which it has cooled it usually is in the form of blunt cones, which are of a blackish color externally, and when broken steel-gray, of a metallic lustre and a radiated crystalline texture, friable, soft, and leaving a black mark upon harder bodies. Its specific gravity varies between 4.6 and 4.7, it being but little lighter than black oxide of manganese, from which it is readily distinguished by the ready fusibility of splinters of antimony sulphide when held in the flame of a candle. It is inodorous and tasteless, and insoluble in simple solvents. It is frequently seen as a heavy black or grayish-black and somewhat shining powder. This, "when boiled with 10 parts of hydrochloric acid, dissolves without leaving more than a slight residue, hydrosulphuric acid being evolved. The solution when added to water gives a white precipitate which is soluble in a solution of tartaric acid. After separation of the precipitate by filtration the filtrate gives an orange-red precipitate with hydrosulphuric acid."—U. S.

Purification.—ANTIMONII SULPHIDUM PURIFICATUM, U. S.—Purified sulphide of Antimony, E.; Sulfure d'antimoine dépuré, Fr.; Gereinigtes Schwefelantimon, G.—Sulphide of Antimony 10 parts; Water of Ammonia 5 parts; Water a sufficient quantity. Reduce the sulphide of antimony to a very fine powder. Separate the coarser particles by elutriation, and, when the finely-divided sulphide has been deposited, pour off the water, add the water of ammonia, and macerate for 5 days, agitating the mixture frequently. Then let the powder settle, pour off the water of ammonia, and wash the residue by repeated affusion and decantation of water. Finally, dry the product by the aid of heat.—U. S.

Similar processes have been long in use with the object of freeing antimonious sulphide from arsenic; but it has long since been proven that antimonious sulphide is likewise dissolved to a large extent; and Garot has shown that the ammoniacal liquid, when evaporated, leaves a red residue which contains very little arsenic. Arsenious sulphide is, however, freely soluble in *ammonium carbonate*, which dissolves but little antimonious sulphide. The process devised by Hager is as follows: Mix in a high vessel 1000 parts of levigated antimony sulphide with 100 parts of ammonia-water, sp. gr. .960, and sufficient warm water to permit the mixture being readily stirred; digest for a day at between 30° and 40° C. (86° and 104° F.), add 50 parts of officinal ammonium carbonate, again digest with frequent agitation for 48 hours, then dilute with water, and wash thoroughly. It forms a dark-gray or grayish-black lustreless powder having the properties mentioned above.

Tests.—Commercial sulphide of antimony is sometimes adulterated with coal-dust, or mixtures of powdered coal and chalk are sold in place of it. The latter effervesce briskly with dilute hydrochloric acid, forming a solution containing calcium chloride. On heating 1 part of the sulphide with 10 or 12 parts of hydrochloric acid but very little residue should be left, and a solution should be obtained in which, after the sulphuretted hydrogen has been expelled, stannous chloride should indicate only traces of arsenic (see Bettendorff's test, p. 27). After diluting the acid solution with five or six times its bulk of water, and filtering from the precipitated oxychloride of antimony, the filtrate should give no precipitate or only a slight one by dilute sulphuric acid (lead), should yield with ferrocyanide of potassium merely a slight blue precipitate (iron), and, when mixed with an excess of ammonia and filtered, should furnish a colorless or only a faintly blue filtrate (copper). "If 2 Gm. of the salt be mixed and cautiously ignited in a porcelain crucible with 8 Gm. of pure nitrate of sodium, and the fused mass boiled with 25 Gm. of water,

there will remain a residue which should be white or nearly so, and not yellowish nor brownish (absence of other metallic sulphides). On boiling the filtrate with an excess of nitric acid until no more nitrous vapors are evolved, then dissolving in it 0.1 Gm. of nitrate of silver, filtering again if necessary, and cautiously pouring a few drops of water of ammonia on top, not more than a white cloud, but no red nor reddish precipitate, should appear at the line of contact of the two liquids (absence of more than traces of arsenic).”—*U. S.*

Pharmaceutical Uses.—Sulphuret of antimony, being the commonest and cheapest antimony ore, is employed for preparing the metal and as the source of all compounds of antimony, of which the following are official: *Antimonii et potassii tartaras*, *U. S.* (*Antimonium tartaratum*, *Br.*); *Antimonii oxidum*, *U. S.*, *Br.*; *Antimonium sulphuratum*, *U. S.*, *Br.*; *Liq. antimonii chloridi*, *Br.*

Medical Uses.—Sulphide of antimony is rarely employed in medicine. It was formerly prescribed along with drastic cathartics in the *dose* of from 5 to 15 grains (Gm. 0.30–1.00).

ANTIMONIUM SULPHURATUM, *U. S.*, *Br.*—SULPHURATED ANTIMONY.

Antimonii oxysulphuretum (Lond.); *Antimonii sulphuretum aureum* (Edinb.); *Antimonii sulphuretum præcipitatum* (Dubl.). *Br.*—*Sulfure d'antimoine précipité*, *Fr.*; *Gefälltes Schwefelantimon*, *G.*

Chiefly antimonious sulphide (Sb_2S_3 ; 336), with a very small amount of antimonious oxide.—*U. S.*

Origin.—Both antimonial kermes and golden sulphur appear to have been first obtained by Basilius Valentinus in the fifteenth century. The latter was called *sulphur auratum* by Quercetanus (1603). The former was prepared by Glauber by dissolving black antimony in potash and cooling, and was lauded by Simon (1719) under the name of *alkermes minerale*. Numerous processes for obtaining these preparations have been published, nearly all of them resulting in mixtures of one or both sulphides of antimony with more or less antimonious oxide. The *U. S.* and *Br.* Pharmacopœias now recognize a nearly pure Sb_2S_3 , which, from the synonyms given by the last-named authority, may also be dispensed as golden sulphur. The German Pharmacopœia recognizes only pure Sb_2S_3 .

Preparation.—Purified Sulphide of Antimony in very fine powder 1 part (6 troy-ounces); Solution of Soda 12 parts ($4\frac{1}{2}$ pints); Distilled Water, Diluted Sulphuric Acid, each a sufficient quantity. Mix the sulphide of antimony with the solution of soda and 30 parts (12 pints) of distilled water, and boil the mixture over a gentle fire for 2 hours, constantly stirring, and occasionally adding distilled water, so as to preserve the same measure. Strain the liquid immediately through a double muslin strainer, and drop into it, while yet hot, diluted sulphuric acid so long as it produces a precipitate. Wash the precipitate with hot distilled water until the washings are at most but very slightly clouded by test solution of chloride of barium; then dry the precipitate and rub it to a fine powder.—*U. S.*

This process is identical with that of the Pharmacopœia of 1870, except that solution of soda is now ordered in place of solution of potassa. The British Pharmacopœia follows the same process, but employs a weaker soda solution and a larger amount of sulphide of antimony, the proportion being $4\frac{1}{2}$ Imperial pints of the former to 10 ounces of the latter.

Amorphous sulphide of antimony dissolves readily in cold alkaline liquids, but for effecting the solution of the crystalline sulphide the application of heat is required. The solution contains both sulphantimonite and antimonite of the alkali, the formation of which is seen from the following equation: $4\text{Sb}_2\text{S}_3 + 8\text{NaHO} = 3\text{Na}_3\text{Sb}_2\text{S}_4 + 2\text{NaSbO}_2 + 4\text{H}_2\text{O}$. On adding sulphuric acid both the compounds named are decomposed and antimonious sulphide is precipitated, without the evolution of sulphuretted hydrogen: $3\text{Na}_3\text{Sb}_2\text{S}_4 + 2\text{NaSbO}_2 + 4\text{H}_2\text{SO}_4$ yields $4\text{Na}_2\text{SO}_4 + 4\text{Sb}_2\text{S}_3 + 4\text{H}_2\text{O}$. The precipitate, however, is likely to retain a portion of undecomposed antimonite, which, if remaining in the hot acidulated liquid, is gradually decomposed; to ensure this decomposition, Liebig suggested to pour the hot alkaline solution into an excess of diluted sulphuric acid and to boil the moist precipitate with a fresh portion of such acid.

1 part of sodium hydrate is theoretically able to form sodium antimonite and sulphan-timonite with 4.2 parts of Sb_2S_3 . In practice, however, a much smaller amount of the sulphide should be used, the pharmacopœias ordering 1.66 (*U. S.*) and 2.55 (*Br.*) parts.

Using larger proportions would result in the formation of sodium sulphantimoniate and antimoniate, and finally of antimonious sulphide, Sb_2S_3 . The reaction is likewise influenced by the concentration of the alkaline liquid and by its exposure to air. The adopted processes should therefore be strictly followed in order to obtain as nearly as possible uniform results.

Properties and Tests.—Sulphurated antimony is a reddish-brown (orange-red, *Br.*) powder, insoluble in water and other simple solvents. When heated with twelve times its weight of officinal hydrochloric acid it is nearly all dissolved, with evolution of hydrosulphuric acid gas. The residue, after having been washed and dried, burns with the characters of sulphur and leaves a scanty ash. The solution in hydrochloric acid, when added to water, deposits a white powder. The liquid filtered from this powder yields an orange-red precipitate with hydrosulphuric acid. Water in which the preparation has been boiled should not yield a white precipitate with chloride of barium or with oxalate of ammonium. The last two tests indicate the absence of sulphates and of calcium compounds. The U. S. Pharmacopœia permits a slight opalescence with test solution of chloride of barium. The precipitate, which falls when a solution of 60 grains of sulphurated antimony in sufficient hydrochloric acid is dropped into water, should, after washing and drying, weigh about 53 grains (*Br.*), or not less than 51 grains = 85 per cent. (*U. S.*). Boiled in water with acid tartrate of potassium, the resulting solution is precipitated orange-red with sulphuretted hydrogen (*Br.*), showing the presence of antimonious oxide.

Off. Prep.—*Pil. antimonii comp., U. S.* (*Pil. hydrarg. subchloridi comp., Br.*).

Allied Compounds.—1. *ANTIMONII OXYSULPHURETUM, U. S.* 1870.—*Stibium sulfuratum rubrum, P. G.* 1872; Sulphur stibiatum rubrum, *Kermes minerale, Alkermes aurificum minerale*.—Oxysulphuret of antimony, *Kermes mineral, E.*; Sulfure d'antimoine hydraté, *Kermès minéral, Poudre des chartreux, Fr.*; Mineralkermes, *G.*

Composition, a mixture of Sb_2S_3 and Sb_2O_3 .

This was prepared by boiling for 1 hour 1 part of black antimony with 250 parts of water containing 23 parts of sodium carbonate, filtering and cooling; after 24 hours the precipitate was collected, washed with cold water previously boiled, and dried. The process was proposed by Cluzel, and received the prize of the Paris Pharmaceutical Society in 1806. The reaction is similar to that described above, except that carbonic acid gas is given off. On cooling, a mixture of Sb_2S_3 and Sb_2O_3 is deposited, varying with the relative proportion of the sulphide and carbonate, and with the concentration of the liquid. The solution decanted from the precipitate, on being boiled with a fresh portion of antimonious sulphide, yields again a precipitate of similar appearance, but containing a much larger amount of oxide. Sonnenberg obtained by four successive boilings kermes containing 8, 33, 43, and 67 per cent. of antimonious oxide.

Oxysulphuret of antimony is a purplish-brown, tasteless powder, soft and velvety to the touch, wholly and readily soluble in hot hydrochloric acid, with evolution of hydrosulphuric acid gas, and partly soluble in a hot solution of potassa, leaving a residue soluble in tartaric acid. On examination with the microscope it is found to be a mixture of amorphous globules of the sulphide with minute transparent prisms of oxide of antimony, which latter is dissolved by solution of tartaric acid.

2. *ANTIMONII PENTASULPHIDUM.*—*Antimonii sulphuretum aureum s. præcipitatum, Stibium sulfuratum aurantiacum, P. G.*; Sulphur stibiatum aurantiacum. Sulphur auratum antimonii.—Antimonie sulphide, Golden sulphuret of antimony, Golden sulphur. *E.*; Soufre doré d'antimoine, *Fr.*; Goldschwefel, Sulfaurat, *G.*

This was originally prepared by precipitating an aqueous solution of liver of antimony (see *ANTIMONII OXIDUM*) with an acid, and contained, besides Sb_2S_3 , also variable amounts of Sb_2S_5 and Sb_2O_3 . Instead of such mixtures the German and other pharmacopœias now recognize the pure antimonial sulphide, which is prepared as follows:

A solution of 70 parts of crystallized carbonate of sodium in 250 parts of water is boiled, and mixed with milk of lime containing 26 parts of lime and 80 parts of water. 36 parts of levigated sulphuret of antimony and 7 parts of sublimed sulphur are added, and the whole boiled until the gray color has disappeared, when the liquid is filtered and crystallized. 24 parts of these crystals, which, from the discoverer Schlippe (1821), are known as *Schlippe's salt*, and have the composition $\text{Na}_3\text{SbS}_4 + 9\text{H}_2\text{O}$, are dissolved in 700 parts of water, and added to a mixture of 9 parts of sulphuric acid and 200 parts of water. The precipitate, having the composition Sb_2S_5 , is washed and dried.

It is an orange-colored, odorless, and tasteless powder, which on being slowly heated in a test-tube gives a sublimate of sulphur, leaving a residue of black antimonious sulphide; at a red heat it is completely volatilized.

It should be soluble in 200 parts of ammonia-water at a moderate heat, leaving merely a trace of residue; it should readily dissolve in sulphide of ammonium, and when this solution is acidulated with hydrochloric acid a precipitate is obtained which, after washing with water and while moist, on being agitated with a 5 per cent. solution of ammonium carbonate, and at once filtered, yields a filtrate which is not rendered yellow on acidulating with hydrochloric acid and the addi-

tion of sulphuretted hydrogen."—*P. G.* This test, proving the absence of arsenic, is also available for the other sulphides of antimony.

Medical Action.—Sulphurated antimony has essentially the same medicinal properties as the oxysulphuret, and may be prescribed in the same doses. It is very rarely employed.

Kermes mineral does not differ essentially from other antimonial in its action, but is generally described as being "alterative, diaphoretic, and emetic," although of very uncertain operation. Its dose as an alterative may be stated to be 1 or 2 grains (Gm. 0.05–0.10) twice a day, and as an emetic from 5 to 20 grains (Gm. 0.30–1.20).

APOCYNUM, *U. S.*—APOCYNUM.

Canadian Hemp, E.; Chanvre du Canada, Fr.; Canadische Hanfwurzel, G.

The root of *Apocynum cannabinum*, *Linné*.

Nat. Ord.—Apocynacæ.

Origin.—This perennial herb grows in fields and grassy places and on the border of woods throughout a large portion of the United States. The smooth often purplish stem

FIG. 28.

Apocynum cannabinum: transverse section; magnified 25 diameters.

is about 40 inches (1 M.) high, has rather erect branches, opposite oblong or linear-oblong acute and mucronate leaves, and many-flowered cymes, the corolla being greenish-white or reddish, having five erect lobes and a tube of the length of the calyx; the fruit consists of a pair of slender follicles containing numerous narrow silky tufted seeds. All parts of the plant, which flowers in July and August, contain a white adhesive milk-juice. Its popular name of *Indian hemp* refers to the strong fibres of the stem-bark, which somewhat resemble the bast-fibres of hemp.

Description.—The root is horizontal, several feet long, $\frac{1}{4}$ to $\frac{1}{2}$ inch (6 to 12 Mm.) thick, slightly branched and beset with a very few fibres; when dry, longitudinally wrinkled, and the thinner portions somewhat annulated by deep transverse fissures. It has a brownish-gray or pale-brown color externally, and under the thin corky layer a fleshy whitish bark, which is about as thick as the woody layer, contains laticiferous vessels, and encloses a yellowish or whitish porous wood composed of several rings and radiate by finely medullary rays; in the centre is a thin pith. The root breaks with a short fracture, is inodorous, and the wood tasteless, but the bark develops gradually a very persistent bitter and rather disagreeable taste. It is usually mixed with the lower portion of the stem, which has a smoother and tougher bark and harder wood, the latter enclosing a larger pith.

Constituents.—The earlier analyses of Dr. Knapp and Dr. Griseom (1833) failed to isolate the active principle, but proved the presence of the widely-distributed proximate constituents, among which are stated to be tannin, gallic acid, gum, starch, resin, and wax. J. U. Lloyd (1879) obtained from a fluid extract of this root, on standing, crystals of cane-sugar and a precipitate of white, tasteless, waxy matter. Schmiedeberg (1883) has isolated two principles resembling digitalin in their properties. *Apocynin* is resin-like, amorphous, easily soluble in alcohol and ether, nearly insoluble in water, and becomes inert on being boiled with hydrochloric acid. *Apocynin* is a yellowish glucoside, easily soluble in water and alcohol, insoluble in chloroform, ether, and benzin, and, like apocynin, gives no characteristic reaction with sulphuric acid and bromine.

Fluid extract of apocynum may be prepared by following the directions for making *Extractum gentianæ fluidum*.

Allied Plant.—*Apocynum androsaemifolium*, Linné, is known as *dog'sbane*, and grows in similar localities as the preceding, but appears to be more frequent in New England and Canada. It differs from Canadian hemp chiefly by the spreading stem and branches, the relatively broader leaves, and the bell-shaped, rose-colored corolla with reflexed lobes and a tube longer than the

FIG. 29.

Apocynum androsaemifolium. transverse section; magnified 25 diameters.

calyx. The long rhizome and roots are from $\frac{1}{4}$ to $\frac{1}{2}$ inch (3 to 6 Mm.) thick, and have a pale brownish wrinkled transversely fissured thickish bark, which is about half the thickness of the woody layer, contains groups of stone-cells in the middle part, is of an unpleasantly bitter taste, and separates easily from the tough white finely-porous and delicately rayed wood, enclosing a rather large pith. The starch of this species is much smaller than that of the preceding. Canadian hemp-root has been frequently sold in place of dog'sbane-root. (For microscopical descriptions of both drugs see E. B. Stuart in *Proceedings Amer. Phar. Assoc.*, 1881, p. 468, and E. A. Manheimer in *Amer. Jour. Phar.*, 1881, p. 554.) Bigelow found in dog'sbane a red coloring matter soluble in water and insoluble in alcohol, a trace of volatile oil, and a caoutchouc-like body. The bitter principle was obtained as an extract-like mass.

Medical Action and Uses.—*Apocynum* is a powerful emetic and cathartic, and when it produces vomiting is diaphoretic also. It also promotes expectoration, causes a tendency to drowsiness, increases the urinary secretion, and diminishes the frequency and force of the pulse. Its evacuant properties have sometimes been made available in *dropsy*, but it does not appear in what forms of dropsy, cardiac, renal, hepatic, or splenic, its efficacy has been chiefly shown. Probably it is a mere evacuant of dropsical effusions, the ultimate tendency of the dropsy depending on the nature of its organic cause. There can be little doubt of its possessing this value in common with jalap and other hydragogue cathartics. Possibly it has the advantage of exciting diaphoresis and diuresis, while it purges and vomits. It is said to destroy *intestinal worms*. An infusion and a tincture of the root have both been regarded as tonic and alterative in *dyspeptic* derangements, and as curative of mild cases of *intermittent fever*. These properties are doubtless owing to the bitter principle which it contains. The dose of the powdered root is about 5 grains (Gm. 0.30) as an antiperiodic, and 20 grains (Gm. 1.30) as an emetic. The decoction is usually made with an ounce (Gm. 32) of the root in $1\frac{1}{2}$ pints of water boiled to a pint, and may be given in doses of a wine-glassful three times a day. Some physicians recommend as a diuretic in dropsy an infusion made with a drachm (Gm. 4) of the bark of the root in 8 ounces (Gm. 250) of water, of which half an ounce may be given once in 6 hours.

Dog'sbane is said to be diaphoretic and emetic, without causing much nausea, and to operate more gently and certainly than ipecacuanha; but it deteriorates by keeping. It is also reputed to be tonic, cathartic, and alterative, and to possess anti-syphilitic powers. In reality, its virtues, if it have any that entitle it to a place in the materia medica, are not well defined. The powder of the recently-dried root is emetic in the dose of 30 grains (Gm. 2). From 10 to 20 grains (Gm. 0.60–1.30) may be given as a tonic or alterative in substance, infusion, decoction, or tincture.

APOMORPHINÆ HYDROCHLORAS, U. S.—HYDROCHLORATE OF APO-MORPHINE.

Apomorphinum hydrochloricum, P. G.—*Chlorhydrate d'apomorphine*, Fr.; *Apomorphin-Hydrochlorat*, G.

The hydrochlorate of an artificial alkaloid prepared from morphine.—U. S.

Formula $C_{17}H_{17}NO_2.HCl$. Molecular weight 303.4.

Preparation.—1 part of pure morphine and 20 parts of pure hydrochloric acid are introduced into a strong glass tube having at least fifteen times the capacity of the mixture; the open end is securely sealed, the glass tube introduced into a strong metallic tube closed by a screw-cap, and the whole immersed for 3 hours in an oil-bath heated to between 140° and 150° C. (284° and 302° F.). After cooling, the tube is opened, the liquid diluted with water, and bicarbonate of sodium added in excess. The liquid is decanted from the precipitate, and this is agitated with ether. To the ethereal solution a few drops of hydrochloric acid are added, whereby hydrochlorate of amorphine is separated; this is recrystallized from boiling water and rapidly dried over concentrated sulphuric acid. In this process chloroform may be used in the place of ether.

This process is the one devised by Matthiessen and Wright (1869). The hydrochloric acid, acting upon the morphine at the temperature stated above, merely abstracts 1 molecule of water from the molecule of morphine, and on opening the cooled tube no pressure is observed in it and no gas escapes. During the heating, however, there is considerable pressure in the sealed tube from the volatile acid, and to guard against accidents its enclosure in a strong metallic tube, as directed above, is advisable. A portion of morphine may possibly not undergo the change, and will be precipitated with the apomorphine by the bicarbonate. Morphine being insoluble in ether, it is left behind when the precipitate is treated with this solvent, which readily dissolves apomorphine. On the addition of a little hydrochloric acid hydrochlorate of apomorphine is produced, and, being insoluble in ether, separated in a crystalline condition. The recrystallization of the salt from boiling water renders it perfectly pure. Since apomorphine is soluble in aqueous liquids, the mother-liquor decanted from the precipitate contains notable quantities of the alkaloid, which may be recovered by agitation with ether or chloroform and by treating these solutions with a little hydrochloric acid. The salt as well as the alkaloid should be rapidly dried upon bibulous paper or over sulphuric acid under a bell-glass, and kept in small well-stopped bottles protected from moisture and light.

Matthiessen and Wright have obtained the same compound from codeine and hydrochloric acid, which yield at first *chlorocodid*, $C_{18}H_{20}ClNO_2$, and on continuing to heat in a sealed tube this compound is split into chloride of methyl, CH_3Cl , and apomorphine, $C_{17}H_{17}NO_2$.

Mayer (1871) noticed that hydrochlorate of morphine is more rapidly and at a lower temperature converted into apomorphine by heating it to 120° C. (248° F.) with a solution of zinc chloride of such strength that its boiling-point is at 200° C. (392° F.); the change is then effected in 90 minutes, and the apomorphine or its salt may be obtained pure by the above process, the carbonate of zinc, which is precipitated at the same time, being insoluble in ether.

In 1845, Arppe had obtained *sulphomorphid*, by heating sulphate of morphine with an excess of sulphuric acid and water to 150° C. (302° F.). This is white, nearly insoluble in water, and was proved by Matthiessen and Wright to be sulphate of apomorphine. Arppe had given it the formula $C_{17}H_{18}NSO_4$. Nadler (1873) separated from it the alkaloid and converted it into hydrochlorate.

Properties.—Hydrochlorate of apomorphine is in "minute, colorless or grayish-white, shining crystals, turning greenish on exposure to light and air, odorless, having a bitter taste and a neutral or faintly acid reaction; soluble in 6.8 parts of water and in 50 parts of alcohol at 15° C. (59° F.); slowly decomposed by boiling water or boiling alcohol; almost insoluble in ether or chloroform, and should it impart color to either of these liquids it should be rejected, or it may be purified by thoroughly agitating it with either liquid, filtering, and then rapidly drying the salt on bibulous paper in a dark place. The aqueous solution on gentle warming rapidly turns green, but retains a neutral reaction. Solution of bicarbonate of sodium, added to an aqueous solution of the salt, throws down the white, amorphous alkaloid, which soon turns green on exposure to air, and forms a bluish-green solution with alcohol, a purple one with ether or pure benzol, and a violet or blue one with chloroform. Addition of test solution of nitrate of silver to an aqueous solution of the salt produces a white precipitate insoluble in nitric acid, but instantly reduced to metallic silver by water of ammonia."—*U. S.* "It turns blood-red with nitric acid, dissolves in an excess of solution of soda, the liquid kept in an open vessel becoming in a short time purple, and finally black."—*P. G.* Its concentrated solution yields with potassium permanganate a dingy-green precipitate, soluble brown-yellow in potassa, and brick-red in nitric acid; potassium iodide yields a white gelatinous precipitate insoluble in excess, but soluble in ammonia (Anneessens, 1882).

The pure alkaloid is a white, or more generally a grayish, amorphous powder, rather

freely soluble in water, ether, benzol, and chloroform. On exposure to the air while still moist it rapidly turns green, and then dissolves in chloroform with a blue color. Nadler observed that on being precipitated from its solution in sulphuric acid by ammonia it speedily acquires a reddish-brown color, and yields with chloroform a rose-colored solution. Apomorphine is colored red by nitric acid, brown by iodic acid, and rose-red or amethyst-red by ferric chloride, this last reaction being quite distinct from the blue color produced by the same reagent with morphine.

The salts of apomorphine appear to be slightly soluble in cold water, but more freely so in warm and in acidulated water. The aqueous and alcoholic solutions of the alkaloid and its salts acquire an emerald-green color on exposure to air, at the same time losing their medical properties; apomorphine should therefore not be kept in solution. In order to preserve it for a week or two, Hager recommends the addition of a drop of ether to half a drachm (2 Gm.) of the solution.

Physiological Action.—*On Animals*: The introduction of apomorphine into medicinal dates from 1869, when the first experiments with it were made by Dr. Gee. He found that 2 grains of the muriate of apomorphine given hypodermically to a dog caused vomiting, and in 2 or 3 minutes the animal began to course around the room in a curiously persistent and methodical manner. 3 grains injected into a cat caused the animal to run around in the same manner, and also to turn vaulting somersaults in the air. 2 more grains induced epileptiform convulsions, and 2 additional grains caused perfect relaxation. The next morning the animal was found dead. It is generally held to produce emesis by acting upon the nervous centres governing that act, and not by a direct irritation of the stomach. Chloroform and chloral hinder, but morphia promotes, its operation. In general, an excessive dose is less apt than a moderate one to occasion vomiting; on the other hand, it produces general relaxation and insensibility, impaired reflex susceptibility, and paralysis of the hinder limbs.

On Man: Locally, apomorphine does not usually act as an irritant, for it causes no pain when applied endermically or hypodermically, and even upon the tongue does not produce a painful impression. Yet its subcutaneous injection has sometimes caused indurated swelling. Its effects upon the system are essentially alike whether it be administered by the mouth or hypodermically, but in the former case they are more slowly developed. In 20 minutes after one-fifth of a grain had been taken internally headache, dizziness, oppression, and qualmsiness were complained of; the face grew pale, there was copious salivation, the pulse was infrequent, small, and feeble, and free vomiting occurred in from 10 to 20 minutes. In some cases there is said to have been drowsiness rather than the apathy of depression (Dujardin-Beaumetz). Sometimes there is retching, or, again, vomiting without effort occurs. This operation is apt to be repeated several times at intervals of a few minutes, and is followed by a quiet sleep. No marked action upon the pulse is observed except during the emetic operation, when it tends to become slower than natural, as well as feebler and smaller; but it speedily returns to the normal rate. Unlike antimony, ipecacuanha, and other nauseant emetics, it neither irritates the stomach nor causes diarrhœa, nor has it the former effect like mechanical emetics, and it operates more promptly than any of them, even more so than some mechanical emetics. By repetition it does not appear to lose its efficacy, but whatever tends to blunt sensibility impairs its action. Thus it acts but feebly upon animals under the influence of chloroform or chloral; all morbid conditions in man that induce a like condition have the same effect, as stupor, asphyxia, etc. It may produce its specific action by absorption through the sound skin; so a gentleman who sometimes had his hands wetted with solutions of this agent vomited frequently, was depressed, uncomfortable about the head, and unfit for work.

Some persons appear to be readily poisoned by apomorphine, which then produces, usually, a degree of sedation which may reach full collapse. This has happened even in robust subjects. In one nausea occurred at the end of 10 minutes; in 3 minutes more the patient grew very giddy and pale, and fell to the ground; he then broke into a cold sweat and appeared to be dying, but he vomited copiously and recovered. One-thirty-second of a grain was very unwisely injected in the case of a child affected with capillary bronchitis. Violent and repeated vomiting took place, the patient grew as pale as wax, and had a tracheal rattle, but it survived. A drunkard affected with albuminuria had injected one-sixth of a grain of muriate of apomorphine. Vomiting presently took place, and then sudden syncope; the pulse was extinct and respiration hardly perceptible; the skin was pale and livid and covered with a cold sweat; there was complete extinction of consciousness and sensibility. Under electrical stimulus the man was saved (Dujardin-

Beaumetz). Very similar effects occurred in the following case: A middle-aged woman, suffering from sore throat, received a hypodermic injection of one-sixteenth of a grain of muriate of apomorphine. Besides the symptoms last mentioned there occurred convulsive twitchings of the corners of the mouth. For some hours after the return of consciousness she was inclined to faint. In a case of quinsy one-sixth of a grain was injected subcutaneously. In 10 minutes the patient suddenly threw himself backward and flexed his arms rigidly; the pulse was very small, the skin cool, and the heart-sounds feeble. Opisthotonos followed, the man supporting himself on the neck and heels. In a few minutes the rigidity disappeared and the patient sank into a deep sleep. A man fifty-two years old, suffering from bronchitis, received a subcutaneous injection of one-fifteenth of a grain of muriate of apomorphine. He did not vomit, but in 7 minutes he became collapsed and died. The autopsy threw no light upon the immediate cause of his death (Ungar).

Pecholier, a professor of Montpellier, has published a detailed history of the poisonous effects produced in himself by the hypodermic injection of about one-sixth of a grain of this substance. He lay with his limbs extended, inert, and unconscious, his face livid, his tongue protruding, and his breathing suspended. Strange to say, however, the pulse was full and firm and the temperature natural. Another injection like the first was administered! It brought on copious vomiting, immediately followed by complete collapse, in which, besides the phenomena just mentioned, the pulse grew feeble and irregular and the limbs cold. From this state of imminent death the patient was rescued by hypodermic injections of sulphuric ether and sinapisms, after which reaction took place rapidly (*Bull. de thérap.*, cii. 353).

According to Harnack, the action of apomorphine may be described, using the conventional language of the day, in the following manner: 1. In man and in Mammalia capable of vomiting a moderate dose excites the centre of emesis, but large doses depress and even paralyze it. 2. In rabbits the respiratory centre is affected in a similar manner. 3. The centre of voluntary motion in rabbits is strongly irritated, even to convulsions, by small doses; dogs and cats are excited to active movements resembling those due to volition. 4. In rabbits, cats, and frogs the centres of sensation appear to be depressed. 5. Striated muscles in frogs have their irritability lessened by this agent, but in higher animals and in man it is uncertain whether the muscular relaxation which occurs is due to an action on the spinal marrow or on the muscular fibres. 6. The heart, in frogs, is paralyzed.

The elaborate experiments of Reichert (*Inaugural Thesis*, Univ. of Penna., 1879) led him to numerous conclusions, of which the greater number agree with these. He also remarked that the drug produced copious salivation and left no lesions behind it after causing death.

Medical Uses.—The sedative, or rather the depressing, action of apomorphine has been occasionally invoked. Thus in the case of a boy in *maniacal delirium*, with dilated and insensible pupils, one-tenth of a grain given hypodermically produced in a few minutes calmness, and then vomiting, after which he slept, and the next morning was well. In India *sunstroke* has been treated in the same way, one-sixteenth of a grain producing emesis, followed by a speedy reduction of temperature and return of consciousness (*Practitioner*, xxiv. 456). It is said to have produced relaxation of a *rigid os uteri*, and it has been given hypodermically with negative or only palliative results in *epilepsy*. In a case of attempted suicide by a man who took the estimated quantity of 6 grains of *strychnia* one-third of a grain of apomorphine was injected hypodermically within half an hour. Immediately the spasms subsided, vomiting took place, and the patient recovered (Glisan). It has also been given hypodermically in the *convulsions* of children, with the effect of arresting them (*Medical News*, 1882, p. 391). It has been administered similarly in cases of alcoholic *intoxication*, and dissipated the condition rapidly after free vomiting had taken place (*Practitioner*, xxx. 211). In a case of poisoning with *oil of bitter almond* it acted as a prompt and sufficient emetic in the dose of one-eighth of a grain hypodermically. Half a grain administered in the same manner in 3 minutes produced copious emesis in a case of poisoning with *carbolic acid*, and the patient recovered. A similar result occurred when a man had been poisoned by swallowing $1\frac{1}{2}$ pints of *kerosene*. The like expedient has been used to cause the expulsion of a *foreign body* from the œsophagus. In *quinsy*, when swallowing is very difficult, this medicine may be used hypodermically to excite vomiting with the intention of breaking the abscess. It is generally thought to be contraindicated in affections of the air-passages, on account of its tendency to produce a profuse watery secretion from the bronchia; yet

it has sometimes been given in emetic doses, and with advantage, in cases of *branchorrhœa* and of *foreign bodies* in the larynx or trachea, and has been recommended in membranous *croup*. Smidowitsch used it in the latter disease and in *spasmodic croup* with alleged advantage, giving large doses, such as 1 grain in the course of a day for several successive days (*Med. Record*, xvii. 346). In minute doses it appears to be applicable to some of the conditions which antimony is used to remove, especially when, in *laryngitis* or *bronchitis*, the mucous membrane is dry and irritable. Kormann, Kushel, and others have found it serviceable in bronchitis and catarrhal pneumonia. It was given in minute doses of from $\frac{1}{120}$ to $\frac{1}{60}$ of a grain, and, without causing vomiting or interfering with digestion, it converted the dry into moist râles, facilitated expectoration, and reduced the fever (*Med. Record*, xx. 290).

Administration.—The use of this product is very limited. Fortunately, the cases for which it is exclusively adapted are very few indeed, as the above enumeration of them demonstrates. The difficulty of preserving it forms another obstacle to its employment, although it is alleged not to lose its special mode of action when its color changes to a green or olive tint. Even this change is said to be preventible by adding glycerin or glucose to its solution, while the former renders muriate of apomorphia more soluble. By the stomach the dose for a child, when it is to be repeated, is about $\frac{1}{120}$ grain (Gm. 0.0005); for an adult, from $\frac{1}{60}$ to $\frac{1}{10}$ grain (Gm. 0.001–0.006). A single hypodermic dose for an infant is from $\frac{1}{30}$ to $\frac{1}{16}$ grain (Gm. 0.002–0.004); for a child of ten years, $\frac{2}{10}$ grain (Gm. 0.003); for an adult, $\frac{1}{10}$ grain (Gm. 0.006) subcutaneously, or $\frac{1}{2}$ grain (Gm. 0.013) by the mouth. For hypodermic injections a 1 per cent. solution is eligible.

AQUA, U. S., Br.—WATER.

Aqua communis, P. G.—*Eau*, Fr.; *Wasser*, G.

Natural water in the purest attainable state (U. S.), cleared, if necessary, by filtration (*Br.*) through alternate layers of sand and charcoal.—P. G. 1872.

Composition H_2O . Molecular weight 18.

Properties.—Water is often combined in nature, as in many crystalline compounds, and is very abundant in the free state. Natural water is an excellent solvent for most gases and many salts, but it is rarely found pure; B. M. Brackemridge and Dr. E. Stieren observed (1860) chemically pure water in the spring of a ravine known as “the Dark Hollow” in Allegheny county, Pa. With few exceptions *spring-water* contains carbonic acid gas in solution, and by its agency dissolves some carbonate and sulphate of calcium and carbonate of magnesium from the soil. Such water precipitates an insoluble lime-soap from solution of ordinary soap, and is called hard. This hardness may be removed by expelling the excess of carbonic acid by heat: the carbonate and a portion of the sulphate of calcium, also magnesium carbonate if present, are thus precipitated. A similar precipitation takes place in rivers, from the water of which, owing to its extended surface, the carbonic acid gas is mostly given off: hence *river-water* is usually soft. Both spring- and river-waters contain variable quantities of salts of alkalies in solution, of which they cannot be deprived except by distillation.

Rain- and snow-water are free from such saline compounds, except the portions falling first; these contain particles of dust and various organic and inorganic matters which had been suspended or dissolved in the air. Among them, ammonia, iodine, chlorine, and nitric acid have been found, the latter more particularly during a thunder-storm, the former two elements occasionally, while ammonia or allied compounds are always present in inhabited regions. It is advisable, therefore, to collect rain-water only some time after the rain has commenced falling, and as far removed from dwellings as possible; it will then contain a little carbonic acid, which has been dissolved from the air.

The purity of running and well-water is affected by the nature of the surrounding soil and the proximity of decaying animal or vegetable matter, the decomposition-products of which may find an outlet into the former by natural drainage, sometimes from a considerable distance, and render such water unwholesome and unfit for many purposes. The refreshing taste of spring-water is mainly due to the carbonic acid dissolved therein. Of secondary importance is the small quantity of saline compounds contained in it. When the latter is permanently increased beyond a certain quantity the spring is called a *mineral spring*. (See *AQUÆ MINERALES*.)

Most spring-waters are unfit for chemical and pharmaceutical uses, but may often become adapted therefor after boiling and filtering. River-water, if not naturally bright and transparent, is improved by filtration through sand and charcoal, and may then be

employed if nearly free from organic matter, the amount of which may be approximately ascertained by a dilute solution of permanganate of potassium, which will permanently impart its color to the water as soon as the organic matter and other deoxidizing agents accidentally present have been destroyed or oxidized. But distilled water is best for all the purposes indicated. Its taste is insipid, owing to the absence of carbonic acid or to the minute quantity of this gas absorbed by contact with air.

At the temperature of 0° C. (32° F.) water freezes, forming transparent crystals of ice; if entirely undisturbed, it may be cooled to several degrees below this point without freezing, and if now slightly agitated will at once congeal, the temperature rising to the freezing-point in consequence of the liberation of latent heat. Water impregnated with salts, particularly such as are readily soluble in it, freezes at a lower temperature, the ice being free from the compounds which were dissolved in the water. Hence, water equal in purity to distilled water may be obtained by melting perfectly clear and transparent ice under conditions which preclude the admixture of dust and other impurities. *Sea-water*, which has the specific gravity 1.027 and contains about $3\frac{1}{2}$ per cent. of salts, yields ice of as great purity as river-water.

The boiling-point of water is 100° C. (212° F.), and rises beyond this temperature if notable quantities of salts, etc. are dissolved in it or if the pressure is increased; on the reduction of pressure water boils at a lower temperature.

The density of distilled water at 15° C. (59° F.) or at 15.5° C. (60° F.) is by general consent regarded as the unit by which the density of liquid and solid bodies is measured. In Europe, however, this unit is sometimes taken from water at its greatest density, and several of the tables published in the U. S. Pharmacopœia (1880) are based upon this unit. The specific gravity of water decreases with the rise of temperature, and increases gradually as the temperature is lowered until $+4^{\circ}$ C. (39° F.) is reached, when it has its maximum density, becomes lighter again toward the freezing-point, and expands very considerably when passing into the solid state, ice having the specific gravity 0.916. When converted into vapor, water expands to nearly seventeen hundred times its bulk, and forms a transparent and colorless gas having the specific gravity 0.455 at 100° C. (212° F.); it has therefore less than one-half the density of atmospheric air. When mixed with air it condenses into minute drops, to which the opaqueness of steam is due; the over-saturation of air with aqueous vapor causes a similar condensation in the atmosphere, hence the appearance of clouds.

Tests of Purity.—Water is “a colorless limpid liquid, without odor and taste at ordinary temperatures, and remaining odorless while being heated to boiling, of a perfectly neutral reaction, and containing not more than 1 part of fixed impurities in 10,000 parts. The transparency or color of water should not be affected by hydrosulphuric acid or sulphide of ammonium (absence of metallic impurities). On heating 100 Ccm. of water, acidulated with 10 Ccm. of diluted sulphuric acid, to boiling, and adding enough of a dilute solution of permanganate of potassium (1 in 1000) to impart to the liquid a decided rose-red tint, this tint should not be entirely destroyed by boiling for 5 minutes (absence of more than traces of organic or other oxidizable matters).”—*U. S.*

Pharmaceutical Uses.—*Aqua destillata, U. S., Br.*—The utility of water as a solvent and vehicle is well known; it is employed in preparing most chemicals, constitutes the solvent of the medicated waters, decoctions, and infusions, and most solutions and syrups, and as an addition to alcohol is present in many of the fluid extracts, tinctures, etc.

Physiological Action of Cold Water.—Water constitutes by far the larger portion of the bulk of all organized beings, and is essential to their organic constitution as well as to the molecular actions and movements by which life is manifested. It is important, therefore, as an article of food which directly supplies one constituent of the body; it is not less so as a means of promoting the solution of solid food in the digestive organs and facilitating its absorption; it is equally the solvent of all the secretions and excretions, and the vehicle by which the latter are carried out of the body. But all natural water is not adapted for food. The greater part of the water in the world is contained in the ocean; another large portion consists of spring- and of river-waters which are so mineralized as to be unfit for ordinary drinking, or of other waters in certain sluggish rivers and in marshes which contain too large a portion of animal or vegetable matter to be wholesome. The purest natural waters are rain-water, which is, however, insipid and contains but little air, and certain springs which are remarkable for their purity as well as the vivacity of their taste. For pharmaceutical, and indirectly for medicinal, purposes, water must be deprived, as far as possible, of its foreign constituents—an object

which is most perfectly attained by distillation. But for many of such objects water that has been boiled or filtered rain- or snow-water has been found sufficiently pure.

In a general way, water acts chiefly as a direct means of modifying the temperature of the body. But the mechanism by which the temperature is raised or lowered is identical with that which quickens or retards organic processes, for it is chiefly upon the degree of activity of the latter that the animal temperature depends. Water at a temperature higher than that of the body is a direct stimulant of the circulation, and therefore of all the functions; cold water, on the other hand, robs the body of a portion of its caloric, and therefore is a direct sedative of the circulatory and the other functions. But cold may indirectly become a stimulant of the animal functions, since it is a property of living organisms to react against whatever powerfully tends to depress them, and this the more vigorously and abruptly the depressing influence has been exerted. Therefore, cold applied to the body in a certain measure and for a given time produces a diminished activity of function, which is followed by a degree of activity greater than that which originally existed. In this manner the primary effect of heat and the secondary effect of cold resemble one another. But cold and heat are conventional terms; they do not designate definite temperatures. The normal animal temperature being about 98° F., whatever is higher than this may be described as heat, whatever is lower as cold. Hence different degrees of heat may be expected to produce different grades of effect, from a mild to a powerful stimulation, and even to the destruction of vitality; and in like manner coolness, cold, congelation, etc. are terms applied to the different degrees in which caloric has been abstracted. It is evident, therefore, that the action of water, and consequently its uses in medicine, will vary between very remote extremes—that it may stimulate moderately or violently, and soothe gently or depress more or less profoundly, according to the conditions which have been pointed out for illustration. The effects of cold water upon the living body are complex: they comprise the direct abstraction of caloric, the diminished production of it, and a multitude of reflex effects due to the relations between the skin and the internal organs. The loss of caloric by the contact of cold water with the skin is more or less completely balanced by the generation of caloric through the organic changes which are incessantly active in every tissue. Hence the interior of the body in health maintains a certain average temperature, or within two or three degrees of it, whatever may be the temperature of the surrounding medium. With the abstraction of caloric all the vital processes are depressed, the skin grows pale and shrivelled, and the internal organs are overloaded with blood; the pulse beats slowly, the secretions are diminished, and the muscles torpid. Taken internally, cold water occasions a sense of coolness in the throat and stomach, and afterward in the rest of the body; but if the water be very cold and taken in large quantity, it may produce in the stomach severe pains which radiate to the chest and abdomen and give a violent shock to the whole nervous system—effects which are accompanied by spasm or by collapse, or by both in succession. If these effects are not fatal, reaction, with fever, is apt to occur. The transient application of cold to the skin is so quickly followed by reaction that the effects seem to be those of direct stimulation; the cutaneous circulation becomes more active, a sense of warmth with gentle perspiration ensues, and through this reflux and flux of the blood and the excitation of the nervous system all of the functions are quickened. Indeed, it cannot, we think, be doubted that the chief value of cold water applied to the skin in disease consists not in its direct action as cold, but in its indirect action as a stimulant of all the functions. Yet the direct abstraction of caloric may in certain exceptional cases be useful. The local effects of cold water, as distinguished from those of cold applied in other ways, are essentially the same as those which have been described—viz. diminished circulation and calorification, followed by a more or less distinct reaction.

Medical Uses of Cold Water.—According, then, to the circumstances under which it acts, cold water may be refrigerant, excitant, sedative, astringent, tonic, debilitating, or perturbating. It may be used to check febrile and inflammatory processes, to stimulate a torpid and oppressed nervous system, to arrest spasm, to relieve congestion and pain, to abate excessive secretion, hæmorrhage, etc. Among the diseases in which it has proved most useful are *continued fevers*, in which the temperature is extremely high, and provided no intercurrent inflammation complicates them. Cold water in the form of douche, baths, sponging, and wet wrappings has been employed with decided benefit in many cases of *typhus fever*, *typhoid fever*, *scarlet fever*, *variola*, etc.; and the douche or other similar shock with cold water has proved curative in various forms of *intermittent fever*. It may be used in either of several conditions: (1) To reduce the hyperpyrexia; (2) to provoke a reaction in the rapidly adynamic forms of these diseases;

and (3) to lessen the delirium, stupor, and other cerebral and spinal symptoms which arise at the height of the attack. Of these the last is by far the most important in relation to the use of cold water. But apart from quite exceptional cases, all the benefits derivable from the cold immersion or the douche-bath may be obtained by simply sponging the skin repeatedly with cold water and giving cool water to drink as much as the patient desires or tolerates, for the use of cold water as a drink in fevers is prescribed by instinct as well as reason. The same is true of it in *inflammation of the stomach*. Pounded ice mixed with bran forms a most efficient poultice for *sore throat*, including *tonsillitis* and *diphtheria*, and its efficacy is increased by ice melting in the mouth. The same or any other convenient mode of applying cold has often been successful in preventing the formation of *abscesses*, mammary, inguinal, and others. The application of wet compresses around the inflamed joints in acute articular *rheumatism* has not produced the bad consequences which it was supposed would follow from a reperussion of the morbid fluxion, and such applications, when made with an alkaline liquid, have often proved extremely salutary. The general cold bath has been used in this disease with hyperpyrexia, but sometimes with the result of inducing inflammatory complications of the heart and lungs, and sometimes of causing death (*Practitioner*, x. 79; xi. 263). But in a certain number of cases of hyperpyrexia, with symptoms of cerebral rheumatism—a complication of the gravest description—cold baths have appeared to mitigate the gravity of the attack and bring about a cure (Woillez, *Bull. de théér.*, xcix. 344; Raynaud, *Arch. gén.*, Jan. 1881, p. 105). The average temperature of the baths used in these cases may be stated as 68° F., and the extremes as 60° F. and 75° F. On reviewing the cases the relation between the cerebral symptoms and the hyperpyrexia is far from being apparent, and the benefit derived from cold baths appears to have been due far more to the calming influence of the low temperature upon the nervous system than upon the mere abstraction of caloric. Cold water is one of the best applications for a variety of local inflammations, such as *burns*, *scalds*, *intertrigo*, and the *stings* of insects. Cold is one of the most potent means of arresting *hæmorrhage*, whether from the nose, lungs, stomach, bowels, or uterus, or from wounds. In such cases it should be applied as near as possible to the source of bleeding. In uterine hæmorrhage ice and iced water have been introduced into the uterus with complete success and without injury. *Serofula*, *chlorosis*, and *anæmia* are diseases which have some elements in common, chief among which is impoverishment of the blood. Whether this condition be primary or secondary, the use of cold water internally and externally improves nutrition, and thereby tends more or less to moderate or to remove the defects of nutrition upon which the diseases depend. It is in this way—that is, by its direct stimulant and indirectly corroborant action—that cold water in the form of baths, and especially salt and surf baths, tends to remedy *nervous exhaustion* produced by mental or physical excesses. A state of debility, here as elsewhere, requires that so powerful an agent as this should be cautiously applied. In most of the diseases last referred to cold water is used as a stimulant or as an indirect agent for promoting perspiration, but in some others its aid is sought for its direct and continuous action in repressing vascular action and its consequences. Thus in all cases of *hyperæmia of the brain*, whether arterial or venous, the excitement of the one and the stupor of the other condition may be mitigated by cold water duly applied to the head. Irrigation with cold water, or the constant application of an ice-poultice to the scalp, with the hair closely clipped, and, still more powerful, the cold douche, will often succeed in allaying violent delirium or restoring consciousness in deep coma. *Insanity*, when acute and accompanied with heat of head, yields to the same method, especially if the body be at the same time immersed in a bath at 95° F. and the treatment be continued daily for several hours at a time. The same method is entirely applicable to the treatment of *mania-à-potu* in violent patients and for the relief of narcotism in *poisoning by opium*. In *sunstroke* the brain-symptoms appear to be due not only to an excess of blood within the cranium, but also to the excessive heat of the blood itself, which is denoted by a surface temperature of 109° to 111° F. Cold water and ice frictions appear to be the most successful, as they are plainly the most natural, remedies for this fatal affection.

Most of the spasmodic affections may be treated by cold water. *Hysteria* is favorably modified by cold bathing, as by all influences that strengthen the system generally and the nervous functions in particular. *Convulsions* of whatever sort, attended with fullness of the cerebral blood-vessels, should be treated by cold applications to the head and the nape of the neck; *coma* with stertor, and also spasms induced by anæsthetics in very nervous women, have been relieved by applying ice over the side of the neck.

Epilepsy has been favorably affected by the use of ice-bags to the cervical spine, and *tetanus* of the idiopathic form has been repeatedly cured in ancient and in modern times by cold affusions. Even traumatic tetanus has got well under the direct application of ice to the spine. A number of cases of anomalous *paralytic* and *spasmodic* affections, caused by fatigue, fright, and other mental impressions, have been cured by a course of hydropathic regimen after the failure of other remedies (Friedmann, *Monthly Abst.*, vi. 540). *Chorea* was formerly treated by cold affusions on the spine and by the ice-bag, but the former was apt to affright the timid children who are most frequently affected with the disease, and the latter was difficult of application. Sulphuric ether applied to the spine in spray is perhaps more efficient, but is only palliative. Cold bathing, and especially sea-bathing, are of great value in this disease. Among diseases of the digestive organs amenable to treatment by cold water is *constipation*, as the oldest and most recent records demonstrate. It has often been employed successfully by causing the patient to walk upon a cold stone pavement, to have cold water dashed over the limbs, or to have it applied to the abdomen by means of wet compresses, while copious draughts of the same liquid were taken. The last-mentioned methods have been successfully employed to overcome the obstinate constipation of *lead colic*. Apparently hopeless *intussusception* of the bowel appears to have been overcome by large enemata of ice-water (Kormann, *Practitioner*, xxv. 212).

In surgery the applications of cold water are important and numerous. It is the most convenient as well as the most efficient remedy for *contusions*, including those to which a joint has been subjected by its *dislocation* or the soft parts by *fractures* of bones, etc. The full benefit of the treatment is best secured by its earliest possible application after the injury, for then it prevents the excessive exudations which embarrass and retard the cure. The utility and the mode of action of the remedy are just the same in the treatment of *wounds* which are not likely to unite directly or by the first intention: and, indeed, even these heal more readily under its use, provided that the severed surfaces are maintained in close apposition; while contused and lacerated wounds, whose union is usually hindered by inflammation, close all the more readily when this process is abated by cold water. The repressive action of cold water is well illustrated by its power of preventing the development of local non-traumatic inflammations, such as *boils*, *carbuncles*, *whitlows*, *acute orchitis*, etc. In all of these affections, if steadily maintained, it arrests their development, but its intermittent application is useless or worse. *Ulcers*, especially of an indolent and ill-conditioned sort, are often cured by cold and moisture combined, by which the nutrition of the part is rendered more active and normal. The water may be applied on compresses, by washing, and, above all, by the *douche*. The two former are the most appropriate for irritable, and the last for indolent, ulcers. The repressive power of cold water is well exhibited in the treatment of *burns* and *scalds*; provided that it be applied immediately after the injury and steadily kept in operation, it will tend to prevent ulterior changes of tissue dependent upon inflammation. The more extensive the injury the less appropriate does this method become. The strangulation of *hernia* is often due to a distension of the blood-vessels of the tumor, and in so far its reduction may be facilitated by whatever tends to disgorge the swelling of its blood; cold water has proved efficient for this purpose in many cases. Even ice and freezing mixtures have been applied with the same object, but they are not free from the danger of producing mortification. In like manner, certain *venous dilatations* have been diminished, particularly those of the *rectum*, the *uterus*, and the *penis*. No better palliative for *hemorrhoids* exists than frequent ablutions with cold water, especially after stool. It is most efficiently applied with a sponge. Acting in a similar manner, pellets of ice have been administered to produce contraction of the *œsophagus* above and around a *foreign body* impacted in it, and render the use of the probang more efficient (*Bull. de thérap.*, cii. 374). Ice has been extensively and efficiently employed to produce anæsthesia and local congelation, and facilitate the performance of many minor surgical operations, such as *opening abscesses*, *removing tumors*, *evulsion of toe-nails*, and even the destruction of *cancers* by chloride of zinc and their obliteration by systematic pressure (Arnott, *Times and Gazette*, 1879, i. 347, 396, 533). The hypodermic injection of cold water has been used as an anodyne in *neuralgia*, *toothache*, and *articular rheumatism*, and as a substitute for *morphea injections* where it was desired to cure the habit of using the latter. That the mitigation or the suspension of pain by this operation is real in many cases cannot be doubted, but it is almost certain that such relief is due, chiefly if not entirely, to expectant attention. (See *Med. News*, xii. 258, 361.) This opinion is strengthened by the fact that the effect has been obtained by the injection of warm as well as of cold water. Cold water or ice may be used to relieve various local pains,

whether inflammatory or neuralgic. Abscesses are examples of the first, and neuralgia of the face is an instance of the second.

The internal use of cold water requires to be cautiously guarded; the risk of drinking it too freely when the system is exhausted by heat has been pointed out. It is not readily absorbed from the stomach in other atonic states of this organ, and if largely taken during or too near a meal it is very apt to interfere with digestion. It should not be used freely during pulmonary, and especially bronchial, inflammations, nor in diarrhœa. It is better tolerated and is often salutary in acute *dysentery*. Baths at a lower temperature than 50° F. are unsafe for children and old persons at all seasons, and when serious disease exists of any organ essential to life the temperature should not be lower than 75°. In any case cold baths should be of very short duration, and active exercise used during and after them. If local applications of cold water occasion chilliness, they should not be continued. Cold baths should not be taken immediately after a meal, nor when the air is chilly, nor when the mind is distressed. Early morning baths are invigorating, but cold baths before bedtime are of great utility in summer by rendering sleep sounder and more refreshing. In cold bathing the head should always be wetted before the rest of the body, and after the bath the skin should be stimulated by rubbing it with coarse cloths.

Local cold baths, applied to the head, the pelvis, and the feet, are employed to relieve congestion and stimulate the circulation in these parts, and thus prevent or remove the effects of vascular stagnation. Their sedative or their stimulant operation will be determined by their duration, the temperature of the water, the manipulations employed at the same time, etc. Cold water is often employed by *irrigation*—that is, by directing a stream of it over some portion of the body; in an *epithem* or mass of lint, sponge, or other porous material kept saturated with the liquid, or by means of pounded ice, which is sometimes mixed with nitrate of potassium and chloride of ammonium in order to form a freezing mixture; by *ablution*, which consists in applying cold water, with more or less friction, to the surface of the body in order to allay the heat of skin and promote diaphoresis in febrile states, etc.; by *affusion*, in which large quantities of cold water are poured over the body, previously washed or not with hot water and soap, by which means the functions of the skin are quickened and sometimes a salutary crisis is brought about. The *douche* is a form of affusion in which a continuous stream of water falls from a height upon the body, adding a mechanical stimulus to that produced by the cold water; the *shower-bath* is a modification of the same method, in which the stimulus is very gentle, and therefore adapted to persons who are comparatively feeble. The so-called *hydropathic* measures, which consist essentially in enveloping the body in wet wrappings, which are in turn surrounded by dry ones, while the patient drinks abundantly of cold water, have for their object the production of profuse perspiration, by means of which the blood may become purged of deleterious matters circulating with it. The purification may become general or be made local by restricting the application of wet compresses to the ailing parts. This last-named method is of very general application, and is useful in all injuries of joints and other local injuries, as well as in almost all internal inflammations, including those of the joints, lungs, and abdominal and pelvic viscera. The sweats produced by topical as well as by general wet applications have sometimes an offensive smell, which probably shows that effete, and therefore deleterious, substances are eliminated by means of them.

Physiological Action and Medical Uses of Warm Water.—Water of a higher temperature than that of the body may be applied in the form of vapor or of liquid. A vapor-bath at 120° F. may increase the pulse-rate to 145 or more, rendering the respiration difficult, causing hæmoptysis, producing fulness of the head, congestion of the brain, and even apoplexy. The more fully the atmosphere is charged with moisture, the greater is the suffering of the system in proportion to the elevation of the temperature, because the less caloric is lost by radiation; under the same circumstances, however, the body rapidly loses weight by perspiration. The internal secretions, and the urine particularly, are notably diminished. These conditions are carried to an extreme limit in the Russian vapor-bath, and are intensified by other methods of stimulating the skin, such as violent frictions and flagellation with slender softened rods. It has been found that a person unaccustomed to such baths may lose nearly a pound in weight by the operation of a single one. For domestic and medical purposes a vapor-bath may be constructed by merely surrounding the patient, seated in a chair, with a tent of blanket or other impermeable stuff and introducing steam within the enclosure. The head need not be included in the covering. Very soon active diaphoresis will commence. The vapor of warm water may also be diffused throughout an apartment by boiling a kettle or other convenient vessel or by slaking lime in the neighborhood of the patient. The latter expe-

dient is to be recommended in cases of *membranous croup*; the others are usually employed in the treatment of acute and chronic muscular *rheumatism*, in chronic articular rheumatism and *gout*, and in cases of *paralysis* that require muscular stimulation. This vapor-bath is also beneficial in *dropsy*, especially when it is produced by cold and in the scarlatinous form; in *eruptive fevers* when the eruption is tardy and imperfect; in all chronic *diseases of the skin* in which the integument is torpid, dry, and hard: and in cases of profuse sweating due to a relaxed state of the skin.

As the capacity of water for caloric is three thousand times greater than that of air, the former is capable of producing the phenomena of heat much more energetically than the latter. When water warmer than the body (99° to 113° F.) is swallowed, it excites a local and diffusive warmth, quickens the pulse, and increases the perspiration and urine. The hotter the water the more decided are these effects. The *warm bath* (100° to 105°) tends to check exhalation from the parts of the body immersed, but increases it from the surface exposed to the air; but before this effect takes place the exposed parts become congested and a sense of fulness and discomfort is experienced in the head and face. The skin grows red, the pulse and respiration are quickened. Sweating follows the bath, especially if encouraged by warm bed-clothing, and there is a general sense of relaxation, and usually an inclination to sleep. The local action of water of the temperature mentioned is to relax the tissues and allow the blood to accumulate in them, thereby tending to withdraw it from remoter parts. Hence the utility of this measure in lessening *congestions* of the brain and other internal organs, and in relieving *pain*, *muscular spasm*, and *fever*. The greater the surface exposed to the action of the bath the more efficient is its operation, particularly in relaxing spasm and allaying internal pain, as is familiarly exhibited by the efficacy of this agent in cases of *dislocations of joints*, in *spasms of the gall-ducts, ureters, intestines, uterus*, etc. If the body, after the action of a hot bath, is subjected to the sudden contact of cold water, a reaction occurs which is usually accompanied with profuse perspiration.

The general warm bath is an important hygienic instrument, by means of which the skin is cleansed of its accumulation of effete secretions and its functional activity is augmented. It is also an almost indispensable agent in modifying the nutrition of the skin, and thereby promoting the cure of many *cutaneous diseases* in their chronic forms. Warm baths have long been used in the treatment of fevers, whether in the *eruptive fevers* in which the exanthem appears tardily or imperfectly, or in these and in *typhus* and *typhoid fevers* for the purpose of moderating delirium, diminishing stupor, or calming nervous symptoms, such as spasm, twitching, etc. It has even been claimed that when the last named of these fevers is treated by "permanent" warm baths the temperature is rapidly lowered, the course of the attack is shorter and milder, and the mortality is diminished (Reiss, *Zeitsch. f. klin. Med.*, iii. 389). If even these statements were accepted literally, the difficulties of employing the method, especially in diarrheal affections, are sufficient to render it practically unavailable. It is one of the most efficient agents in the treatment of chronic *rheumatism*, especially in the form of sulphurous mineral waters. It is an important adjuvant in all the varieties of *albuminuria* and of *diabetes*. Prolonged warm baths are most efficient auxiliaries in all excito-motor derangements, but especially in *convulsion* and muscular *spasm*, and also in *insanity* of nearly every type. In certain cases of *paralysis*, and particularly in rheumatic paraplegia, the efficiency of the warm bath is sometimes remarkable. Its stimulant and revulsive operation is valuable in various intestinal disorders, and notably in *cholera infantum* and *acute dysentery*. Its depurative action is frequently available in *serofula*, *chlorosis*, and constitutional *syphilis*. According to Mosler, enemata of hot water stimulate the discharge of bile in catarrhal *jaundice*. The hot bath tends to relieve extreme muscular exhaustion, and is available in cases of apparent death from *asphyxia*, *strangulation*, and *intoxication*, and when the new-born child fails to breathe, or does so imperfectly, owing to debility and not to cerebral congestion.

Partial warm baths are applied to the feet, the hips, and sometimes to the hands. Warm foot-baths (at about 98° to 100° F.) draw the blood away from the brain, and thereby promote sleep and relieve pain and congestion of the head and trunk. They are very efficient in arresting the formation of *coryza*, *sore throat*, *pulmonary catarrh*, *laryngitis*, especially of the spasmodic form, and muscular *rheumatism*, and in promoting the *menstrual flow*. If the water is hot enough to produce a painful impression on the skin, it stimulates the whole system, and is more apt to occasion a sense of fulness than relief, and to prevent sleep instead of promoting it. The warm hip-bath is used at about the same temperature (98° to 101° F.), and is especially adapted to allay painful *abdominal* and *pelvic disorders*, such as *biliary, renal*, and *uterine colic* and *strangury*, to relieve reten-

tion of urine, and bring on retarded menses and the hæmorrhoidal flow. Fomentations with warm water by means of cloths, sponges, spungio-piline, poultices, etc. may be regarded as partial warm baths, and are used to relieve the tension of the skin in local phlegmonous inflammations, and at the same time, by increasing the amount of blood in the part, to promote suppuration. Such fomentations of the mammæ favor the secretion of milk, and, through the sympathy of these glands with the uterine system, sometimes excite the menstrual flow. This last effect has been secured by prolonged injections of warm water into the vagina, which are also useful in recalling suppressed lochia and allaying pain in the pelvis. Enemas of warm water are habitually used to evacuate the bowels. It is alleged that irrigation of the rectum with water at from 100° to 110° F., and repeated every two hours during the active stage of dysentery, has a marked influence, not only in palliating the tenesmus, but in shortening the attack (Reid, *New York Jour. of Med.*, xxiv. 603). Warm sand- or mud-baths are often employed at thermal springs in the treatment of chronic rheumatism, gout, general dropsy, etc. Water so hot that its contact can just be borne without scalding is sometimes used to arrest certain inflammations in debilitated parts, such as *panuris*, frost-bite, the effects of local contusions, etc.; to arrest local perspirations and general colliquative sweats; to check capillary hæmorrhage; and to relieve various pains, such as earache, toothache, neuralgia, colic, uterine pain, etc. Its stimulant power is familiar in its arresting the bleeding from leech-bites and similar small wounds. Following a German method, Dr. F. H. Hamilton applied successfully, in the treatment of lacerated and contused wounds, local baths of warm water, and also fomentations of cotton batting soaked in water at 95° to 110° F. and renewed every half hour. Subsequently, he employed the same method successfully in arresting traumatic gangrene (*Trans. Med. Soc. of State of New York*, 1875 and 1879). Water at 160° F. has been used to check the capillary hæmorrhage which is apt to follow the removal of Esmarch's tourniquet. But Dr. C. T. Hunter has found that similar hæmorrhages are efficiently checked by water at 125° or 130° F. (*Phila. Med. Times*, x. 89). Hot-water injections have been used with prompt effect to arrest uterine hæmorrhage (Barker), and that variety of it produced by laceration of the cervix or hæmorrhage from a like injury of the vulva has been controlled by means of water at 110° to 115° F. A stream of such water directed upon the undilated cervix uteri at term will bring on labor, or thrown into the cavity of a relaxed and bleeding uterus will induce its contraction (A. H. Smith). In various inflammatory and congested states of the eye the stimulant action of hot water is at once the simplest and most efficient remedy. The water, it is recommended, should be as hot as the patient can comfortably bear with the hand, and should be applied by drenching or by being thrown against the eye with the hand while the face is bent over a basin containing the water. This operation should be repeated every hour or two or only two or three times a day, as may be required (Connor, *Am. Jour. of Med. Sci.*, Oct. 1881, p. 466). Still better, the face may be immersed in the water while the eye is kept open. According to Pétrequin, warm water is a better solvent for cerumen than oil, glycerin, etc. Boiling water may be employed to produce a powerful stimulant or revulsive action, as in cases of asphyxia and prolonged syncope. Its use requires great caution, and is not as safe as the application of a hammer or similar metallic instrument previously immersed in boiling water.

AQUÆ MEDICATÆ.—MEDICATED WATERS.

Aquæ destillatæ, P. G.; *Aquæ stillatitiæ*.—Distilled waters, E.; *Eaux distillées*, *Hydrolats*, Fr.; *Destillirte Wässer*, G.

Preparation and Properties.—The above names are applied to waters which have been impregnated with volatile substances. All odorous plants and parts of plants impart their odor, and to a certain extent also their taste, to water which is distilled therefrom. This is due to a considerable extent to the volatile oils passing over with the vapor of water; but in many instances the flavor of such distilled waters differs more or less from that of the aqueous solutions of the corresponding volatile oils, and we must therefore assume that besides the volatile oils other volatile compounds, acids, and probably ethers, pass over and remain dissolved in the water, whereby the flavor is modified and nearly always becomes more agreeable. In preparing medicated waters distillation should be resorted to whenever practicable.

The drugs are preferably used in the fresh state if they can be thus obtained, since during the drying process more or less of the volatile constituents are lost by evaporation, and, in common with the others, often modified in composition. In some cases where the

oil-cells are well protected, as in cinnamon-bark, or the oil is produced only by contact with water, as in bitter almonds, the material may be preserved in the dry state for a long time without deterioration. In all cases where the oil-cells are not situated on the surface, as they are in many leaves, the drug should be suitably comminuted, so that it may be easily penetrated by the hot water and the oil-cells ruptured.

In distilling medicated waters over a naked fire great care should be taken to prevent the material from being burned, otherwise an empyreumatic odor and taste will be imparted to the distillate; this is obviated by placing the drug upon a diaphragm, or setting within the still another vessel perforated on the sides and bottom, so that the vapors will pass through it without unnecessary obstruction. If steam is used the danger of burning is avoided; in this case a jet of steam may be conducted to the bottom of the still, the contents of which are thereby heated to the boiling-point. If dry material is used, allowance must be made for its swelling on becoming thoroughly permeated by the water, as it might otherwise fill the still and pass into the condenser. Some materials when boiled in water foam considerably, and portions of the decoction are then apt to be carried over mechanically, rendering the distillate colored and otherwise impure. This tendency to foam over will be lessened by adding to the contents of the retort a small quantity of a fixed oil.

The rapidity with which medicated waters are distilled is of importance, since it has a considerable influence on their flavor and stability. In all cases the waters should be rapidly and thoroughly cooled in the condenser, to prevent the action of the hot water and of the acids which are frequently present upon the tin, and to avoid changes in the volatile oil, which, in its finely-divided condition, are apt to occur. Waters which have been insufficiently cooled very frequently become ropy in keeping. It is advisable, therefore, to distill them slowly and cool the condenser well with a sufficient supply of water.

A peculiar odor is observed in some waters immediately after they have been distilled from tin vessels or condensed in tin worms, but not when glass vessels have been used. If the waters are exposed to the air in loosely-closed vessels for a few days, this still-odor disappears and the natural odor of the water becomes apparent.

Distilled waters which, like orange-flower water, are not completely saturated with volatile oil, are advantageously prepared of double or triple the officinal strength, either by distilling off only one-half or one-third of the necessary quantity of water, or by having recourse to the process of cohobation, in which case the proper quantity of water is distilled off and a second or third time distilled from fresh portions of the same material. When wanted for use they are diluted with distilled water in the proper proportions. The German Pharmacopœia (1872) directed *concentrated medicated waters* to be prepared of German chamomile, melissa, sage, elderflowers, and linden-flowers, by distilling from 10 parts of the drugs 100 parts of water, adding to the distillate 2 parts of alcohol, and again distilling 10 parts. For use 1 part of these waters was diluted with 9 parts of distilled water.

Distilled waters are best preserved in well-corked bottles, which should be completely filled and protected from the light. Exposed to air and light, they gradually turn sour and lose their agreeable odor.

The U. S. Pharmacopœia allows most medicated waters to be prepared by dissolving the volatile oil in distilled water. To facilitate the solution the oils are now directed to be thoroughly distributed through double the weight of absorbent cotton by gradually adding the oil and picking the cotton apart after each addition; this is a somewhat laborious operation, which is perhaps best facilitated by combing or carding the cotton. When uniformly impregnated the cotton is firmly packed in a glass funnel and exhausted by percolating distilled water through it. The division of the volatile oils was formerly accomplished by triturating them with carbonate of magnesium; but a minute quantity of this salt is always dissolved and the acids which may be naturally contained in the oils are neutralized. In some cases, as in cinnamon-water, a yellow or brownish color is also produced. One of the most important objections to the use of magnesia or magnesium carbonate is found in the action upon the salts of poisonous alkaloids and metals, which are decomposed thereby, with the precipitation of the alkaloids or metallic oxides, unless some acid be added to neutralize the magnesia (T. H. Powers, 1833). Other substances which are completely insoluble in water have been recommended for this purpose, such as powdered silica, kaolin, glass, pumice-stone, paper-pulp, calcium phosphate, and purified animal charcoal. G. G. Percival recommends the dissolving of the volatile oils directly in hot distilled water, and filtering after cooling, whereby a strong and otherwise pure medicated water is obtained.

Tests for Purity.—Medicated waters should evaporate in a clean porcelain capsule without leaving any appreciable residue. The water should not acquire a brown or black color by sulphuretted hydrogen or sulphide of ammonium (metals), or yield with the latter a white sediment, after having been previously rendered alkaline by the addition of ammonia (zinc).

AQUA AMMONIÆ, U. S.—WATER (SOLUTION) OF AMMONIA.

Liquor ammonia, Br.; *Liquor ammonii caustici*, P. G.; *Spiritus salis ammoniaci causticus*, *Ammonia aqua soluta*.—*Ammoniaque liquide*, *Eau* (*Solution*, *Liquueur*) *d'ammoniaque*, Fr.; *Salmiakgeist*, *Aetzammoniak*, *Ammoniak-Flüssigkeit*, G.

An aqueous solution of ammonia having the specific gravity 0.950 (*U. S.*, *Br.*), 0.960 (*P. G.*), and containing 10 per cent. by weight of the gas.

Stronger water of ammonia has the specific gravity 0.891 (*Br.*), 0.900 (*U. S.*), and contains 32.3 (*Br.*), 28 (*U. S.*) per cent. by weight of the gas.

Formula of ammonia gas NH_3 . Molecular weight 17.

Production.—Ammonia is produced during the putrefaction of all organisms and of many organic compounds containing nitrogen; it exists in the air and in the soil in the free state, mostly in combination with acids in the air, as carbonate and nitrite. Ammoniacal salts are met with in most plants and animals. The products of the dry distillation of many nitrogenated compounds contain ammonia, and it is from such a source—namely, from the so-called gas-liquor, a by-product of the manufacture of illuminating gas—that ammoniacal salts are principally obtained. (See AMMONIUM CHLORIDUM and AMMONIUM SULPHAS.)

Preparation.—1. AMMONIA-WATER. Take of Chloride of Ammonium in small pieces, Lime, each 12 troyounces; Water 6 pints; Distilled Water a sufficient quantity. Pour a pint of the water upon the lime in a convenient vessel, and after it has slaked stir the mixture so as to bring it to the consistence of a smooth paste. Then add the remainder of the water and mix the whole thoroughly together. Decant the milky liquid from the gritty sediment into a glass retort of the capacity of 16 pints, and add the chloride of ammonium. Place the retort on a sand-bath and adapt to it a washing-bottle, previously connected with a two-pint bottle, by means of a glass tube reaching nearly to the bottom of the bottle, containing a pint of distilled water. Surround the bottle with ice-cold water and apply heat, gradually increased until ammonia ceases to come over. Remove the liquid from the bottle, and add to it sufficient distilled water to raise its specific gravity to 0.960. Lastly, keep the liquid in small bottles, well stopped.—*U. S.*, 1870.

According to the British Pharmacopœia, 1 pint of strong solution of ammonia is mixed with 2 pints of distilled water.

2. AQUA AMMONIÆ FORTIOR, *U. S.*; *Liquor ammoniæ fortior*, *Br.*—Stronger water (Strong solution) of ammonia, *E.*; *Eau d'ammoniaque forte*, *Fr.*; *Starker Salmiakgeist*, *G.* Take of (Chloride of Ammonium in coarse powder 3 pounds; Slaked Lime 4 pounds; and Distilled Water 32 fluidounces. Mix the lime with the chloride of ammonium, and introduce the mixture into an iron bottle placed in a metal pot surrounded by sand. Connect the iron tube, which screws air-tight into the bottle in the usual manner, by corks, glass tubes, and caoutchouc collars, with a Woulf's bottle capable of holding a pint; connect this with a second Woulf's bottle of the same size; the second bottle with a matrass of the capacity of 3 pints, in which 22 ounces of the distilled water are placed, and the matrass, by means of a tube bent twice at right angles, with an ordinary bottle containing the remaining 10 ounces of distilled water. Bottles Nos. 1 and 2 are empty, and the latter and the matrass which contains the 22 ounces of distilled water are furnished each with a siphon safety-tube charged with a very short column of mercury. The heat of a fire, which should be very gradually raised, is now to be applied to the metal pot, and continued until bubbles of condensable gas escape from the extremity of the glass tube which dips into the water of the matrass. The process being terminated, the matrass will contain about 43 fluidounces of strong solution of ammonia.

Bottles 1 and 2 will now include, the first about 16, the second about 10 fluidounces, of a colored ammoniacal liquid. Place this in a flask closed by a cork which should be perforated by a siphon safety-tube containing a little mercury, and also by a second tube bent twice at right angles and made to pass to the bottom of the terminal bottle used in the preceding process. Apply heat to the flask until the colored liquid it contains is reduced to three-fourths of its original bulk. The product now contained in the terminal

bottle will be nearly of the strength of solution of ammonia, and may be made exactly so by the addition of the proper quantity of distilled water or of strong solution of ammonia.—*Br.*

When ammonium salts are treated with the hydrate of a metal of the alkalies or alkaline earths, the corresponding salts of the metals are formed and ammonia and water are set free. In both the above processes chloride of ammonium and hydrate of calcium are used, the reaction resulting in the production of calcium chloride, ammonia, and water, as follows: $2\text{NH}_4\text{Cl} + \text{Ca}2\text{HO}$ yields $\text{CaCl}_2 + 2\text{NH}_3 + 2\text{H}_2\text{O}$. But while the two processes are identical as far as the chemical reaction is concerned, they differ very considerably in the manipulation. In the first process the materials react upon each other in the presence of much water, resulting, even at the ordinary temperature, in the liberation of much ammonia, and permitting the completion of the process, including the disengagement of the ammonia, at the boiling temperature and in glass retorts. It is important to heat the mixture gradually, so that much of the gas may be given off before the boiling temperature is reached. A rapid heating is apt to cause the extrication of the gas with such violence that the contents of the retort will boil over.

In the British process the materials act upon each other in the dry state, requiring a higher heat, and, in consequence thereof, the employment of an iron retort. This process is mostly followed in the preparation of ammonia on the large scale, when sulphate of ammonium is often substituted for the chloride on account of the cheapness of the former salt. The dry process necessitates greater care in the purification of the gas, which is indicated already by the dark color acquired by the liquid in the wash-bottle. The impurities in the gas are chiefly decomposition-products, resulting from the impurities contained in the ammonia salt and lime. Although the latter is used in excess, carbonate of ammonium may form either from calcium carbonate possibly present or from the decomposition of organic matter. If the wash-bottle is charged with milk of lime, the organic decomposition-products are better retained, and any carbonate of ammonium contained in the gas will be decomposed, yielding ammonia and carbonate of calcium. In preparing ammonia on the large scale it is advantageous to connect the wash-bottle with a series of stoneware receivers shaped like Woulf's bottles, so that the gas which is not absorbed in the first will pass into the second receiver, and so on.

The employment of a considerable excess of hydrate of calcium has been found advantageous to ensure the complete decomposition of the ammonium salt. On account of this excess the residue in the retort will contain a basic calcium chloride having the composition $\text{CaCl}_2.3\text{CaO}$, which, after having been filtered from the lime, may be neutralized by hydrochloric acid and evaporated to dryness, to be utilized as chloride of calcium.

On the large scale ammonia-water is usually made with common water, the natural impurities of which it contains, together, frequently, with notable quantities of iron derived from the iron delivery-tubes employed. Chemically pure ammonia-water may be obtained from this by heating it, or, preferably, the commercial stronger ammonia-water, in a glass flask or retort, and conducting the gas, a considerable amount of which is evolved below the boiling-point of water, by means of glass tubes, into distilled water.

Gaseous ammonia is obtained by passing the gaseous products in the above processes over dry potassa or calcium chloride.

Properties.—1. **GASEOUS AMMONIA.** Ammonia is a colorless gas having a strong penetrating odor and an acrid alkaline taste. It has the specific gravity 0.593. By a pressure of seven atmospheres at 15°C . (59°F .), or when cooled to -40° at the ordinary atmospheric pressure, it condenses into a colorless liquid much lighter than water, which boils a few degrees above this temperature and crystallizes when placed in a mixture of solid carbonic acid and ether at about -75°C . (-102°F .).

2. **AMMONIA-WATER.**—The aqueous solutions of ammonium constitute colorless, transparent liquids possessing the odor and taste of the gas, being lighter than distilled water and having a lower freezing-point than this liquid. They impart a brown color to turmeric-paper, a blue color to red litmus-paper, and a green color to the juice of violet-flowers, and evolve dense white fumes when a glass rod moistened with hydrochloric or acetic acid is held over the liquid. Ammonia neutralizes all acids, forming salts which are mostly colorless and crystallizable, possess a sharp saline taste, and when heated to redness are entirely volatilized, without leaving any residue unless the acid be non-volatile; even the solutions of most ammonium salts, when evaporated or heated to boiling, lose a portion of the ammonia. For the neutralization of 8.5 Gm. of ammonia-water 50 Cem. of the

volumetric solution of oxalic acid should be required (*U. S., Br.*) or 23.5 Cem. of volumetric hydrochloric acid for 4 Gm. of ammonia-water (*P. G.*).

3. **STRONGER AMMONIA-WATER.**—It has the properties of ammonia-water, from which it differs chiefly in specific gravity and greater strength. To neutralize 3.4 Gm. of it should require 56 Cem. of the volumetric solution of oxalic acid (*U. S.*). 5.23 Gm. require 100 Cem. (*Br.*), corresponding, the former to 28 per cent., the latter to 32.3 per cent., NH_3 .

The following table gives the specific gravities of ammonia-waters of different strengths at $14^\circ \text{C. (57.2}^\circ \text{F.)}$, as ascertained by Carius, 1856:

Per cent. NH_3 .	Specific gravity.	Per cent. NH_3 .	Specific gravity.	Per cent. NH_3 .	Specific gravity.	Per cent. NH_3 .	Specific gravity.
36	0.8844	27	0.9052	18	0.9314	9	0.9631
35	0.8864	26	0.9078	17	0.9347	8	0.9670
34	0.8885	25	0.9106	16	0.9380	7	0.9709
33	0.8907	24	0.9133	15	0.9414	6	0.9749
32	0.8929	23	0.9162	14	0.9449	5	0.9790
31	0.8953	22	0.9191	13	0.9484	4	0.9831
30	0.8976	21	0.9221	12	0.9520	3	0.9873
29	0.9001	20	0.9251	11	0.9556	2	0.9915
28	0.9026	19	0.9283	10	0.9593	1	0.9959

Tests.—The solutions of ammonium salts yield orange-colored crystalline precipitates with platinum chloride, and, if not too dilute, white ones with tartaric acid or acid tartrate of sodium. The most delicate tests for ammonia are those of Einbrodt (1852) and of Nessler (1856). *Einbrodt's reagent* is an aqueous solution of corrosive sublimate, rendered slightly alkaline by the addition of a minute quantity of potassium carbonate. The test is applied to an alkaline solution, or if the solution has an acid reaction it should be rendered faintly alkaline by the addition of potassa or soda, when the test-liquid will produce a white cloudiness if only $\frac{1}{50000}$ of ammonia is contained in the solution.

Nessler's reagent is a solution of iodo-hydrargyrate of potassium, made either by saturating a solution of potassium iodide with mercuric iodide, and rendering this alkaline by potassa, or it is prepared from potassium iodide and mercuric chloride. (See *HYDRARG. IODIDUM RUBRUM*.) With solutions of ammonia or ammoniacal salts it gives a brown-red precipitate, or if very dilute an orange color. It may be used for the quantitative determination of minute quantities of ammonia by diluting the liquid so far that with Nessler's solution only an orange tint is produced, which is compared with that obtained from a solution of ammonium chloride of known strength by diluting the latter until the same coloration is produced with the test liquid.

Tests of Purity.—Water of ammonia should evaporate at the temperature of boiling water without leaving any residue (salts). On being neutralized with an acid no empyreumatic odor should be observed. It should not yield a precipitate with lime-water (carbonate), with oxalate of ammonium (calcium), or, either before or after neutralizing by means of nitric acid, with sulphuretted hydrogen. After acidulation with nitric acid it should not be precipitated by nitrate of silver (chloride, etc.) or nitrate of barium (sulphate). A faint cloudiness is permitted on mixing ammonia-water with five times its volume of lime-water, indicating a minute trace of carbonate.

Pharmaceutical Uses and Preparations.—Ammonia-water is extensively employed as a precipitant in the manufacture of most alkaloids, of phosphate of calcium, hydrate of iron, and purified chloride of ammonium; it is used for nearly neutralizing solutions in preparing digitalin and subcarbonate and subnitrate of bismuth, and as a solvent for impurities in the process for santonin. Combined with citric acid as ammonium citrate, it acts as a solvent for certain salts of iron and bismuth which are insoluble in water; it is employed in the preparation of benzoate, phosphate, and citrate of ammonium and of hydrargyrum ammoniatum, and forms an ingredient in the following official preparations:

1. *Stronger ammonia-water*: Spiritus ammoniæ, *U. S.*; Linimentum camphoræ comp., Spiritus ammoniæ aromaticus, Spir. ammon. foetidus, Tinct. opii ammoniata, *Br.*

2. *Ammonia-water*: Linimentum ammoniæ, *U. S., Br.*; Linim. hydrargyri, *Br.*; Spir. ammon. aromat., *U. S.*; Tinct. quiniæ ammoniata, *Br.*

Physiological Action.—The vapor of ammonia causes plants to fade and shrivel and asphyxiates animals immersed in it. Caustic water of ammonia given to animals occasions distress, frequent pulse and respiration, prostration, and rigid spasm before

death. The gastro-intestinal mucous membrane is injected, softened, and covered with bloody mucus, while the blood in the vessels coagulates imperfectly and its corpuscles are disintegrated. It does not appear to increase the alkalinity of the blood or of the secretions, and it is found in the urine oxidized. When ammonia-water is injected into the veins of an animal exhausted by loss of blood and exposure of the viscera, and the congested heart has almost ceased to beat, immediately the heart resumes its action and normal color and the aorta is filled with bright-colored blood (Griswold, *Med. Record*, xv. 532). Applied to the human skin, caustic ammonia excites a sense of warmth, followed by burning pain and more or less vesication, or, if the application be excessive and prolonged, by gangrene of the part. Blisters caused by ammonia are very painful and slow to heal. Ammoniacal vapors in contact with the eye occasion severe pain and inflammation. Inhaled through the nose, they produce sneezing, lachrymation, and burning. In the air-passages they excite violent irritation unless greatly diluted, and if inhaled during a state of insensibility fatal asphyxia may result. The passage of the vapor through the mouth under such circumstances may produce severe inflammation of its lining membrane. Internally, its action upon the healthy system is slight and transient, but in states of nervous exhaustion it is very prompt and distinct. A sense of tension in the temples, exhilaration of the feelings, a consciousness of increased strength, greater warmth of the skin, and an augmented secretion of sweat, urine, and bronchial mucus, are among its most sensible effects, which are not, as in the case of alcohol, followed by a corresponding depression. The action of large doses is not uniform. Sometimes death follows in a few minutes, with symptoms of cauterization of the fauces and larynx, sometimes later with those of gastro-enteritis, accompanied or not with delirium, stupor, and spasm. A drunkard, having swallowed nearly 2 fluidounces of "aqua ammoniæ," survived 4½ days (*Boston Med. and Surg. Jour.*, Aug. 1880, p. 166). After death may be found inflammation and œdema of the fauces and larynx, sometimes of the bronchiæ also, and generally of the œsophagus, stomach, and small intestine. The mucous membrane may even look charred. In other cases, in spite of large doses of the poison and violent symptoms denoting local irritation and nervous exhaustion, the patients recover, although it may be after a long time.

Medical Uses.—*Externally*, ammonia is commonly employed both as an ingredient of stimulating liniments and as a caustic. Under the first-named form it is a very popular palliative for the pains of muscular *rheumatism*, *neuralgia*, *muscular spasms*, etc., and for relieving *congestions*, particularly of the *larynx*, *lungs*, *throat*, and *bowels*. In the latter its greatest utility is limited to the first period of the attack. In neuralgia its caustic is more important than its stimulant action, and is best secured by vesicating the skin wherever the affected nerve is found to be tender, either at its point of emergence from bones, muscles, etc. or where it is ultimately distributed to the skin. The vesication must be superficial for superficial nerves, and deeper for profound ones. It is best effected by saturating a disk of cloth with ammonia, applying it accurately to the skin, and holding it there, covered with some solid substance, until vesication has been accomplished. A salt of morphia dissolved in the ammonia used renders the relief more certain. *Amenorrhœa* has been successfully treated by vaginal injections of a weak solution of ammonia, and the same is true of vaginal *leucorrhœa*. Other cases in which the local substitutive irritation of ammonia is available are—a tendency to *amaurosis* from exhaustion of the retina, in which case the vapor may be cautiously allowed to come in contact with the conjunctiva; superficial *burns* and *frost-bite*; and a general exhaustion or depression of the nervous system in *low fevers*, when a weak solution of ammonia in hot water may be applied by sponging to the whole skin. Ammonia enters into most of the liniments and washes that are used to prevent the *hair* from falling out or to stimulate its growth. *Vulvar pruritus* is said to be benefited by vaginal injections consisting of half a fluidrachm or more of stronger water of ammonia in half a pint of common water. This may possibly be true of pruritus connected with amenorrhœa, but the remedy is useless in most of the other forms, except as a very transient palliative.

By inhalation the vapor of ammonia has been used to arrest the development of catarrhal affections of the throat and air-passages (*bronchitis*, *coryza*, and *pharyngitis*). It is recommended to employ a weak solution. The most successful application of this method is, perhaps, to chronic dryness of the *pharynx* and to chronic *hoarseness*. It has been used as an antidote to *chlorine* and to *bromine*. *Acidity* of the stomach from feeble digestion is benefited by this medicine, and so is the *tympanites* which is often associated with it. In two affections in which spasm of the larynx is a more or less prominent symptom, *whooping cough* and *epilepsy*, the inhalation of ammoniacal fumes has been known to

delay or prevent the paroxysm. The same means are popularly employed to relieve *syncope* from all causes, and also the various conditions which lead to it and to which nervous women are subject. Hence it is the basis of most of the "smelling-salts." It may be cautiously used in all cases of suspended animation, whether from syncope or *asphyxia*. It is, if promptly employed, an antidote to *hydrocyanic acid* and to *alcoholic intoxication*. The best mode of administering it in the former case is by intra-venous injection. For this purpose the official ammonia-water, which is a 10 per cent. solution, is diluted with an equal quantity of pure water, and about a fluidrachm at a time is cautiously injected. The revival of the insensible and apparently lifeless patient is usually very prompt. (Compare *Glasgow Med. Jour.*, iv. 493; *Lancet*, 1879, p. 158; *Med. Record*, xv. 532.) This expedient has been employed successfully in poisoning by privy-gas (*Boston Med. and Surg. Jour.*, Sept. 1882, p. 309). Locally applied, ammonia-water relieves the pain of the stings and bites of *bees*, *wasps*, *spiders*, *mosquitoes*, etc., and a large amount of evidence exists to prove its antidotal power against the bites of *serpents*, both when administered by the stomach and when injected into the veins. The latter method is alleged to be by far the most efficient. The median-cephalic vein is the one generally selected for the operation, and from 5 to 20 drops of strong solution of ammonia in a fluidrachm of water are thrown into the vein with a hypodermic syringe. The clinical facts relied upon for establishing the efficacy of the method are numerous, but the experiments on animals by Fontana in the last century and by some recent observers gave only negative results (*Times and Gaz.*, Dec. 1873, p. 712; *Lancet*, Sept. 19, 1874). Ammonia has been administered in large doses for the purpose of causing *resolution of fibrin* in the right side of the heart and in the great vessels. In three out of four cases the treatment was apparently successful. It is found experimentally that ammonia mixed with blood preserves it fresh and fluid for a long time (Richardson).

Administration.—The dose of water of ammonia is from 10 to 30 drops (Gm. 60–2.00), largely diluted. The stronger preparation is for external use. It may be applied to the skin on some porous tissue saturated with it and covered with an impermeable substance. In from 3 to 10 minutes the desired effect may be expected. Gondret's paste is formed by adding concentrated water of ammonia to a mixture of melted lard and tallow. It may be applied in a disk-shaped layer an inch or two in diameter. It is apt to cauterize the skin too deeply. As a rubefacient ammonia is generally associated with oil or some unctuous substance, and should be applied with gentle friction to the skin.

As an *antidote* any mild vegetable acid (vinegar, lemon-juice) may be employed to neutralize the uncombined ammonia in the stomach. The local irritant effects require demulcent and protective remedies.

AQUA AMYGDALÆ AMARÆ, U. S.—BITTER-ALMOND WATER.

Aqua amygdalorum amararum, P. G.—*Eau d'amandes amères*, Fr.; *Bittermandelwasser*, G.

Preparation.—Oil of Bitter Almonds 1 part (11 grains); Distilled Water 999 parts (25 oz. av. or 24 fluidounces); to make 1000 parts. Dissolve the oil in the distilled water and filter through a well-wetted filter.—U. S.

Made by this process, bitter-almond water is a very unreliable preparation, owing to the variable amount of hydrocyanic acid contained in the oil of bitter almonds. The following will yield a water of definite strength in hydrocyanic acid; and since in this form the latter is scarcely prone to decomposition, such or a similar preparation deserves to take the place of the official hydrocyanic acid and of the present bitter-almond water (see *Amer. Jour. of Pharmacy*, 1874, p. 217):

Bruise Bitter Almonds 12 parts, and express as much fixed oil as possible without the aid of heat. Powder the press-cake, mix it thoroughly with water 80 parts and alcohol 1 part, macerate for 12 hours; distil off 11 parts into a receiver containing alcohol 1 part; determine the amount of hydrocyanic acid in the distillate, and then dilute with a mixture of alcohol 1 part and distilled water 5 parts, so that 1000 parts of the mixture contain 1 part of hydrocyanic acid.

Thus prepared, bitter-almond water is nearly clear, and has a strong odor of hydrocyanic acid and oil of bitter almonds, the latter remaining after the hydrocyanic acid has been removed by means of nitrate of silver.—P. G.

In making bitter-almond water by the latter process the fixed oil is removed, because it hinders the reaction between the amygdalin and emulsin, to complete which maceration

of the expressed almonds with water for about 10 or 12 hours is advisable at a temperature of about 30° or 35° C. (86° or 95° F.). The almond mixture is then placed upon a perforated diaphragm and heat applied to the still. Pettenkofer's process, which has been adopted by the Austrian Pharmacopœia, differs in this: that 11 parts of the powdered bitter almonds are twice mixed with hot water and boiled to dissolve the amygdalin; the expressed decoctions, when cold, are mixed with 1 part of powdered bitter almonds, macerated and distilled as before; the emulsin contained in 1 part of the almond is sufficient to decompose the whole of the amygdalin, and, there being only a small amount of insoluble matter in the still, the distillation proceeds without difficulty even over a naked fire.

When the requisite quantity of water has distilled over, 27 Gm. of the distillate are diluted with 54 Gm. of distilled water, mixed with sufficient magnesia, previously rubbed with water, to render it milky, and with a few drops of solution of potassium chromate; decinormal (volumetric) solution of nitrate of silver is then added until the red color produced by the latter ceases to disappear on stirring; each Ccm. of the silver solution represents .01 per cent. of HCy. A bitter-almond water containing .1 per cent. of hydrocyanic acid will require 10 Ccm. of the silver solution. The strength may also be determined gravimetrically by adding to 1000 grains of the water first a little ammonia, then a slight excess of nitric acid, and finally solution of silver nitrate until a precipitate ceases to appear; this, when washed and dried, should weigh exactly 5 grains: if it weighs more the distillate must be diluted; should it weigh less, which may happen if the almond-powder has not been macerated with water or if the bitter almonds have been mixed with sweet almonds, it is best to redistil the water, adding, if necessary, some common water to the retort, and recovering a quantity calculated beforehand from the weight of the precipitate.

This bitter-almond water has exactly one-twentieth the strength of the diluted hydrocyanic acid, but is much stronger than that of the U. S. Pharmacopœia, the latter corresponding perhaps better with the *Aqua amygdalarum amararum diluta* (vel *Aqua cerasorum*) which the German Pharmacopœia (1872) prepared by mixing 1 part of the above almond-water with 19 parts of distilled water. If the oil of bitter almonds has been previously deprived of its hydrocyanic acid, the bitter-almond water prepared from it will possess no virtues except for imparting flavor.

Medical Action and Uses.—This uncertain—and unsafe as well as uncertain—preparation, as directed by U. S. P., is not official in the British Pharmacopœia. If hydrocyanic acid must be given internally, it may be administered with less risk in the form of cyanide of potassium. The dose of the concentrated German preparation is from 20 to 50 drops (Gm. 1–3), and of the diluted preparation of the same Pharmacopœia, as well as of the American, is 1 or 2 teaspoonfuls (Gm. 4–8).

AQUA ANETHI, *Br.*—DILL-WATER.

Eau d'aneth, Fr.; *Dillwasser*, G.

Preparation.—Take of Dill-Fruit bruised 1 pound; Water 2 gallons. Distil 1 Imperial gallon (= 10 pounds).—*Br.*

The water, which is at first slightly milky if prepared by this process, possesses the odor and taste of dill-fruit.

Medical Uses.—It does not increase the lacteal secretion, but imparts to it an aromatic flavor, which renders its administration in this way convenient in cases of infantile *colic*. It, however, has no advantage in taste or action over anise-water, which it in all respects resembles. It is seldom used in this country.

AQUA ANISI, *U. S.*—ANISE-WATER.

Eau d'anis, Fr.; *Aniswasser*, G.

Preparation.—Oil of Anise 2 parts (22 grains); Cotton 4 parts (44 grains); Distilled Water a sufficient quantity; to make 1000 parts (25 oz. av. or 24 fluidounces). Add the oil to the cotton in small portions at a time, distributing it thoroughly by picking the cotton apart after each addition; then pack it firmly in a conical percolator and gradually pour on distilled water until 1000 parts of percolate are obtained.—*U. S.*

Anise-water may also be prepared by mixing 10 troyounces of bruised anise with 16 pints of water, and distilling 8 pints, as directed by the U. S. P. 1870. It has a more pleasant odor and taste than that made from the oil.

Medical Action and Uses.—Anise-water is an agreeable and useful vehicle for medicines intended to expel *flatus* and to allay *colic* and the pain of laborious digestion. It is often used to mitigate the *gripping* of senna, rhubarb, jalap, and other purgatives, and as a suitable vehicle for magnesia. It is thought also to be an appropriate excipient for expectorant medicines. *Dose*, a fluidrachm (Gm. 4) and upwards.

AQUA AURANTII FLORUM, U. S.—ORANGE-FLOWER WATER.

Aqua aurantii floris, Br.; *Aqua florum aurantii*, P. G.; *Aqua florum naphæ*.—*Eau (Hydrolat) de fleur d'orange*, *Eau de nape*, Fr.; *Örangenblüthenwasser*, G.

Preparation.—Recent Orange-flowers 40 parts (40 oz. av.); Water 200 parts (200 oz. av. or 12 pints): to make 100 parts (100 oz. av. or 6 pints). Mix them, and by means of steam distil 100 parts. Keep the product in well-stopped bottles, excluded from light.—U. S.

The French Codex directs the distillation, by means of steam, of twice the weight of the fresh orange-flowers used. Thus prepared, it is called in commerce *double orange-flower water*, and if it is diluted with its own weight of distilled water it is known as *simple orange-flower water*. The so-called *triple* and *quadruple orange-flower waters* are also met with in commerce, the former being obtained by distilling 3 parts, the latter by distilling 2 parts, of water from 2 parts of fresh orange-flowers.

Distilled orange-flower water is a clear and colorless or slightly opalescent liquid of a very agreeable odor and aromatic taste, which cannot be imitated by preparing the water from the oil of orange-flowers (*neroli*). As distilled from the flowers, it possibly contains some volatile ethers, which are freely soluble in water and not contained in the volatile oil. The Pharmacopœia process, however, is of practical value only to those pharmacists who are fortunate enough to be able to procure the recent flowers; if preserved by the addition of one-half their weight of table-salt, 60 (instead of 40) parts should be used. Occasionally, commercial orange-flower water has separated mucilaginous flocks, which may be removed by agitation with powdered kaolin and filtration. If it has acquired an acid reaction it is advisable to distil it over magnesia. The total absence of metallic salts, resulting from the use of a metallic condenser or from keeping the water in metallic vessels, is proved by its remaining unaffected by hydrosulphuric acid and by sulphide of ammonium. Occasionally distilled orange-flower water has been met with which acquires a red color on the addition of an acid; the cause of this abnormal behavior has not been ascertained, but may perhaps be due to some accidental impurity.

Pharmaceutical Uses.—It forms the base of Syrup. aurantii flor., U. S., Br., and the flavoring constituent of Trochisci acidi tannici, Troch. catechu, Troch. krameriaæ, Troch. sodii santoni., and Troch. ipecacuanhæ, U. S.; in the last, orange-flower syrup is used.

Medical Action and Uses.—Orange-flower water is more remarkable for its delicate and refreshing perfume than for its active medicinal properties. It forms a pleasant flavoring ingredient of many potions, and may be prescribed for nervous persons during attacks of neuralgic *headache*, *pulpitation* of the heart, and a variety of minor *hysteroidal* disorders, the offspring of indolence and self-indulgence.

AQUA CAMPHORÆ, U. S., Br.—CAMPHOR-WATER.

Aqua camphorata.—*Eau camphrée*, Fr.; *Kampferwasser*, G.

Preparation.—Camphor 8 parts (88 grains): Alcohol 16 parts (176 grains or 3½ fluid drachms); Cotton 16 parts (176 grains); Distilled Water a sufficient quantity; to make 1000 parts (25 ounces av. or 24 fluidounces). Dissolve the camphor in the alcohol, and add the solution to the cotton in small portions at a time, distributing it thoroughly by picking the cotton apart after each addition. Expose the cotton to the air until the alcohol has nearly evaporated; then pack it firmly in a conical percolator, and gradually pour on distilled water until 1000 parts of percolate are obtained.—U. S.

Take of camphor broken in pieces half an ounce; distilled water 1 gallon. Enclose the camphor in a muslin bag, and attach this to one end of a glass rod, by means of which it may be kept at the bottom of a bottle containing the distilled water, the other end of the rod terminating just below the stopper of the bottle. Having thus put the camphor into the water, close the mouth of the bottle, macerate for at least 2 days, and then pour off the solution when it is required.—Br.

This is intended to be a saturated solution of camphor in water. R. Rother (1871) has

shown that very cold water dissolves more camphor than can be retained in solution at the ordinary temperature, the excess crystallizing out, leaving, after filtration, such a saturated solution as is intended by the pharmacopœias. In preparing camphor-water by the above processes cold water should therefore be used. Prepared with the aid of magnesium carbonate by the process of the U. S. P. 1870, camphor-water contained, according to G. F. H. Markoe (1865), 2 grains of camphor in the fluidounce; that of the British Pharmacopœia, only half a grain. W. B. Addington suggested (1873) that a still stronger camphor-water may be obtained by dissolving the camphor in a small quantity of alcohol before triturating with the magnesium carbonate (calcium phosphate is preferable), by which means it is very finely divided.

Medical Action and Uses.—The proportion of 1 grain of camphor which is contained in each $\frac{1}{2}$ fluidounce of this preparation is not sufficient to develop the more potent effects of the drug, yet quite enough to sustain the nervous system in the minor grades of exhaustion and prostration into which it is apt to fall in *low fevers* on the one hand, and in states of *nervous debility* and disorder on the other. Its anodyne and antispasmodic influence is shown in mild attacks of *neuralgia*, of *nervous headache*, of *colic*, of *dysmenorrhœa* depending upon an irritable state of the uterus, in *after-pains*, in *hiccup*, and in *nervous palpitation of the heart*. The average dose is about a tablespoonful (Gm. 16), which may be repeated at intervals of an hour or two.

AQUA CARUI, Br.—CARAWAY-WATER.

Aqua carui.—*Eau distillée de carvi*, Fr.; *Kümmelwasser*, G.

Preparation.—Take of Caraway Fruit bruised 1 pound (avoirdupois); Water 20 pounds. Distil 10 pounds (avoirdupois) (1 gallon Imperial).—*Br.*

This water has the flavor of the fruit in a marked degree.

Medical Uses.—The properties of caraway-water are almost identical with those of anise-water; it may be given in the dose of a fluidrachm (Gm. 4) or more.

AQUA CHLORI, U. S.—CHLORINE-WATER.

Liquor chlori, Br.; *Aqua chlorata*, P. G.; *Aqua chlorinii*, U. S. 1870; *Chlorum solutum*, *Aqua oxymuriatica*.—*Solution of chlorine*, E.; *Eau chlorée*, *Chlore liquide*, Fr.; *Chlorwasser*, G.

An aqueous solution of chlorine containing at least .4 per cent. (U. S. P. G.), not less than .6 (*Br.*), of the gas.

Symbol of chlorine Cl. Atomicity univalent. Atomic weight 35.4.

Origin.—Chlorine was discovered by Scheele (1874), and was at first called dephlogisticated muriatic acid, afterward *oxymuriatic acid*, under the supposition that it was a compound of muriatic acid with oxygen. Gay-Lussac and Thénard (1809) showed that from its behavior it might be regarded as an element, a view which was strengthened by the researches of Humphry Davy (1810), who called it chloric gas, which name was changed to chlorine by Gay-Lussac (1813). Chlorine is widely distributed in nature, but owing to its affinity for other elements it is never found in the isolated state. It exists in many minerals, in most spring-waters, in sea-water, in plants, and in animals, and is liberated from the chlorides by the combined action of sulphuric acid and an oxidizing agent.

Preparation.—Take of Black Oxide of Manganese 10 parts (90 grains); Hydrochloric Acid 40 parts (360 grains or 6 drachms); Water 75 parts (675 grains or $1\frac{1}{2}$ fluidounces); Distilled Water 400 parts (3600 grains or 8 fluidounces). Place the oxide in a flask; add the acid, previously diluted with 25 parts (225 grains or $\frac{1}{2}$ fluidounce) of water, and apply a gentle heat. Conduct the generated chlorine, by suitable tubes, through the remainder of the water, contained in a small wash-bottle, to the bottom of a bottle having the capacity of 1000 parts (20 fluidounces), into which the distilled water has been introduced, the neck of which is loosely stopped with cotton, and which is to be kept during the operation at a temperature of about 10° C. (50° F.). When the air has been entirely displaced by the gas disconnect the bottle from the apparatus, and, having inserted the stopper, shake the bottle, loosening the stopper from time to time, until the gas ceases to be absorbed. If necessary, reconnect the bottle with the apparatus, and continue passing the gas and agitating until the distilled water is saturated. Finally, pour the chlorine-water into dark amber-colored glass-stoppered bottles, which must be completely filled therewith, and keep them in a dark and cool place.—*U. S.*

This process is identical with that of the British Pharmacopœia, except as to weights

and measures, but both aim at a saturated solution of chlorine and water with the simplest manipulation. In following the Pharmacopœia the best corks should be used for the generating-flask and wash-bottle, since porous corks are readily penetrated and destroyed by chlorine gas. This gas is generated by the action of hydrochloric acid upon binoxide of manganese, chloride of manganese, chlorine, and water being produced; $\text{MnO}_2 + 4\text{HCl}$ yields $\text{MnCl}_2 + \text{Cl}_2 + 2\text{H}_2\text{O}$. If the undiluted acid of the Pharmacopœia is employed the evolution of chlorine gas will commence, without heat being applied, and will continue for some time. Diluted as directed, the application of heat is necessary from the beginning. A strong heat should not be used at first, since hydrochloric acid gas would be carried over into the wash-bottle. The loss of acid may be entirely avoided if the oxide of manganese is used in small lumps instead of in powder, and in sufficient quantity so as not to be covered by the acid. Although chlorine is soluble in water to a considerable extent, it does not dissolve very readily; hence gas-bubbles will soon pass through the water without being much diminished in size. The pharmacopœias direct the use of receiving-bottles which are but partially filled with water. The atmosphere in the upper part of the bottle will gradually be displaced by the heavier chlorine, and when the latter begins to escape from the mouth of the bottle, this is disconnected from the apparatus, loosely corked, and agitated, when the gas will be absorbed. The bottle, which should be protected from the light, is then replaced, and the operation repeated until no further diminution of the pressure is observed in the bottle on being gently agitated when filled with chlorine. The British Pharmacopœia directs the agitation of the bottle only after the evolution of chlorine gas has ceased; much of the gas may be lost by not repeating the agitation several times.

The temperature best suited for dissolving the chlorine in water is 10°C . (50°F .). Near the freezing-point of water a solid chlorine hydrate, $\text{Cl}_2 \cdot 5\text{H}_2\text{O}$, is formed, which is less soluble in water than the gas. At the temperature indicated water dissolves, according to Schönfeld, 2.585 times its volume of gas, the solubility being gradually lessened as the temperature rises. When the operation is finished it is well to pour the chlorine-water at once into small glass-stoppered vials, which should be completely filled and kept in a cool and dark place. The stoppers should be secured by twine, or, as suggested by Hager, by bladder which has been previously coated with a mixture of collodion and paraffin.

For the preparation of chlorine on the large scale, as in the manufacture of chlorinated lime, sulphuric acid is sometimes used in addition to the black oxide of manganese and hydrochloric acid, when all the chlorine contained in the latter is obtained and manganous sulphate is left in solution. Or the generation of hydrochloric acid and of chlorine is effected in one operation by the use of sulphuric acid, sodium chloride, and black oxide of manganese, in which case the sulphates of sodium and of manganese remain behind.

For special purposes chlorine may be prepared by the action of hydrochloric acid upon potassium bichromate; $14\text{HCl} + \text{K}_2\text{Cr}_2\text{O}_7$ yield $3\text{Cl}_2 + 2\text{KCl} + \text{Cr}_2\text{Cl}_6 + 7\text{H}_2\text{O}$, the result being chlorine, potassium chloride, chromic chloride, and water. Or potassium chlorate may be decomposed by hydrochloric acid, with the formation of chlorine, potassium chloride, and water; $6\text{HCl} + \text{KClO}_3$ yields $3\text{Cl}_2 + \text{KCl} + 3\text{H}_2\text{O}$, but the gas is in this case apt to be contaminated with hypochlorous acid.

During the preparation and handling of chlorine-water the operator should be careful not to inhale the gas, on account of its irritating and poisonous properties. Should its effects be perceived, it is advisable to carefully inhale a little sulphide of ammonium, which is decomposed by the chlorine into chloride of ammonium and sulphur. It should, however, be cautiously used, since an excess of this compound is likewise poisonous. A little ammonia, sufficiently diluted, may also be taken with advantage.

Properties.—Chlorine is a greenish-yellow, irrespirable, corrosive gas, having the spec. grav. 1.47, and becoming liquid at 15°C . (59°F .) under a pressure of four atmospheres. Liquid chlorine is dark yellow, does not congeal at -90°C . (-130°F .), and boils at -33.6°C . (-28.5°F .). Chlorine is not inflammable, but is capable of supporting combustion.

Chlorine-water is a clear, greenish-yellow liquid possessing the suffocating odor and acrid, irritating taste of chlorine, evaporating without leaving any residue, but separating crystals of chlorine hydrate when cooled to the freezing-point of water. Its specific gravity is 1.003 (*Br.*) when saturated at 6°C . (42.8°F .) (*Berthollet*). It instantly discharges the color of a diluted solution of indigo and bleaches vegetable coloring matters generally. Exposed to light, it is decomposed into hydrochloric acid and oxygen. It is a powerful

oxidizing agent, and this property serves to readily ascertain its strength. A fluidounce of it, mixed with a solution of 14 grains of pure ferrous sulphate, does not produce a blue precipitate with ferricyanide of potassium, indicating that the salt has been completely oxidized to ferric sulphate, and proving that the water contains 0.4 per cent. of chlorine.

Tests.—Chlorine-water should evaporate without leaving any residue. Agitated with an excess of mercury until the odor of chlorine has disappeared, the remaining liquid reddens litmus-paper but faintly, if at all (hydrochloric acid). The test of the British Pharmacopœia indicates a strength of 0.6 per cent. It is applied as follows: A solution of 20 grains of iodide of potassium in an ounce of water yields with 439 grains (1 fluidounce) of chlorine-water a deep red-colored liquid, which requires for the discharge of its color 750 grain-measures of the volumetric solution of hyposulphite of sodium, corresponding to 2.66 grains of chlorine.

On mixing 35.4 Gm. of chlorine-water with a solution of 0.09 Gm. of iodide of potassium in 20 Gm. of water, the resulting deep-red liquid should require for complete discoloration at least 40 Cem. of the volumetric solution of hyposulphite of sodium (corresponding to at least 0.4 per cent. of chlorine).—*U. S.* The requirements of the German Pharmacopœia are identical with these, 25 Gm. of chlorine-water, 1 Gm. potassium iodide, and 28.2 Cem. of the hyposulphite solution being used, and the determination made in the presence of starch solution, whereby the red color of dissolved iodine is changed to blue.

Physiological Action and Medical Uses.—Although not directly relating to chlorine-water, it may here be mentioned that Binz inferred from his experiments that in the frog the primary action of chlorine is to paralyze the nerve-centres, and that it has no direct poisonous action upon the heart (*Archiv exper. f. Pathol. u. Pharmacol.*, xiii. 155). The action of chlorine-water in large doses and internally is that of an irritant poison. In a diluted state it acts locally as a stimulant and disinfectant, and on absorption is supposed to quicken all the functions and purify the blood in typhoid forms of disease depending upon an animal poison generated within the system or absorbed from without. It is highly probable that this view of its operation is derived chiefly from its power of neutralizing the foul odors of decomposition. Clinical reports of its effects in zymotic diseases demonstrate the incapacity of the reporters to observe and judge, rather than the virtues possessed by the medicine. When the types of the several diseases described are considered, and their inherent tendency to recovery or to death, the share in the results to which other medicines were equally with this one entitled, and the partial exclusion by its use of more active and probably hazardous remedies, it is difficult to accept the positive and laudatory accounts of its virtues as representing even an approach to truth. We believe, therefore, that the efficacy of chlorine in *typhus fever*, in *scarlet fever*, in *diphtheria*, in *small-pox*, etc. is wholly undemonstrated, except as far as it is a palliative of certain local and subordinate symptoms, such as *putrid angina* and a burning heat of the skin. In all forms of *sore throat* attended with fetid discharges and an ulcerated or torpid condition of the mucous membrane washes and gargles of chlorine-water may be used with the same advantage as other stimulant disinfectants. A like statement may be made regarding other forms of disease in which the intestinal discharges are peculiarly fetid, as in certain cases of *typhoid fever* and of typhoid types of *dysentery*, *small-pox*, etc. Chlorine-water is to be commended as a wash or dressing for all forms of *sores* which have a fetid discharge, even for *cancerous* ulcers, and as a lotion for the skin when the crusts formed by *small-pox* pustules become offensive. Chlorinated water has been reputed to have the power of preventing the infection of *syphilis* and of *puerperal fever*—in the one case by its use in washing the genitals after impure coition, and in the other by cleansing the hands of accoucheurs after attendance upon cases of the disease. Supposing the alleged effect to be real, which is by no means proven, it is not quite clear that an equally diligent use of soap would not have been followed by an equal degree of immunity. Chlorinated oil, made by passing chlorine gas through olive oil, has been found efficient in *scabies* and a parasiticide generally. At one time chlorine gas was used by inhalation in various bronchial affections, and especially in *phthisis* and *fetid bronchitis*, but atomized chlorine-water is preferable.

The *dose* of chlorine-water is from 1 to 4 fluidrachms (Gm. 4–16), largely diluted. For inhalation, when atomized, a solution of from 5 to 10 drops (Gm. 0.30–0.60) in water may be used. *Antidotes*: after emesis with warm water, albumen in the form of milk, white of egg, veal-broth, etc., flour and water, or lime-water.

AQUA CHLOROFORMI, Br. Add.—CHLOROFORM-WATER.*Eau de chloroforme, Fr.; Chloroformwasser, G.*

Preparation.—Take of Chloroform 1 fluidrachm; Distilled Water 25 fluidounces. Put them into a two-pint stoppered bottle and shake them together until the chloroform is entirely dissolved in the water.—*Br. Add.* A fluidounce represents about 2 minims of chloroform.

Medical Uses.—The dose prescribed by the British Pharmacopœia is from $\frac{1}{2}$ fluidounce to 2 fluidounces.

Beurmann claims that chloroform remains unchanged for a long time in its watery solution (*Bull. de thérap.*, cv. 97). It is well adapted for a mouth-wash or gargle, both to relieve the pain of *toothache* and *sore throat* and to stimulate the mucous membrane of the mouth and pharynx, and internally to relieve all abdominal pains, but especially those of *gastralgia*. The acid taste of the preparation may be removed by mint-water, orange-flower water, etc. On the other hand, it may be used to mask the taste of various medicines or to render the stomach more tolerant of them.

AQUA CINNAMOMI, U. S., Br., P. G.—CINNAMON-WATER.*Eau de cannelle, Fr.; Zimmtwasser, G.*

Preparation.—Oil of Cinnamon 2 parts (11 grains); Cotton 4 parts (22 grains); Distilled Water a sufficient quantity; to make 1000 parts (25 oz. av. or 24 fluidounces). Add the oil to the cotton in small portions at a time, distributing it thoroughly by picking the cotton apart after each addition; then pack it firmly in a conical percolator, and gradually pour on distilled water until 1000 parts of percolate are obtained.—*U. S.*

The British Pharmacopœia directs the distillation of 1 Imperial gallon (10 pounds) of cinnamon-water from 20 ounces of bruised Ceylon cinnamon, or in proportion of 8 parts of water from 1 part of bark. The present German Pharmacopœia recognizes as *Aqua cinnamomi* a distilled water formerly called *Aqua cinnamomi spirituosa (s. vinosa)*, and made by distilling 10 parts from a mixture of sufficient water, 1 part of alcohol specific gravity 0.832, and 1 part of Chinese cinnamon.

Properties.—Obtained by any one of these processes, cinnamon-water is somewhat turbid, but gradually becomes clear. Made from the oil, it has the odor and a somewhat harsh taste of cinnamon, but if distilled from the bark its odor is more fragrant and its taste decidedly sweet. Cinnamon-water made with magnesia has a yellowish color, unless carbonic acid gas is passed through it or a small quantity of some other acid is added. In contact with the air the volatile oil is oxidized, and crystals of cinnamic acid and small particles of a brownish resin are frequently separated.

Off. Prep.—Mistura cretæ, *U. S., Br.*; Mist. guaiaci, Mist. spiritus vini gallici, *Br.*

Medical Action and Uses.—Cinnamon-water possesses the stimulant and carminative properties of the bark from which it is derived, but is seldom used except as a vehicle for other medicines with which it can co-operate. It is most commonly employed in mixtures for flatulent *colic* and *diarrhœa*, and in the latter affection as a vehicle for chalk, astringents, and opiates.

AQUA CREASOTI, U. S.—CREASOTE-WATER.*Eau créosotée, Fr.; Kreosotwasser, G.*

Preparation.—Creasote 1 part (55 grains); Distilled Water 99 parts; to make 100 parts ($12\frac{1}{2}$ oz. av. or 12 fluidounces). Agitate the creasote with the distilled water until dissolved, and filter through a well-wetted filter.—*U. S.*

Medical Uses.—This preparation contains in every 2 fluidrachms rather more than 1 minim of creasote, and is a convenient form of that medicine for all the cases in which it should be given diluted, and also as a topical application in *leucorrhœa*, *gleet*, *burns*, *chilblains*, *ulcers* (especially such as are attended with an excessive, thin, or fetid discharge), *gangrene*, and various cutaneous eruptions, particularly *prurigo*, *eczema*, *syccosis*, etc. *Dose*, from 1 to 4 fluidrachms (Gm. 4-16).

AQUA DESTILLATA, U. S., Br., P. G.—DISTILLED WATER.*Eau distillée, Hydrolat simple, Fr.; Destillirtes Wasser, G.*Composition H_2O . Molecular weight 18.

Preparation.—Water 1000 parts; to make 800 parts. Distil the water from a suitable apparatus provided with a block-tin or glass condenser. Collect the first 50 parts and throw them away. Then collect 800 parts and keep the distilled water in glass-stoppered bottles.—*U. S.*

Take of water 10 gallons. Distil from a copper still connected with a block-tin worm; reject the first half gallon and preserve the next 8 gallons.—*Br.*

When ordinary water is heated to ebullition the gases and volatile compounds dissolved therein are also vaporized and carried off with the vapors of the water, which, if condensed, would then be more highly charged with these volatile compounds; hence the necessity of rejecting the first portion of the distillate, as directed by the pharmacopœias. On the other hand, if the distillation is continued until all the water is vaporized from the still, the last portions are apt to be contaminated with volatile products resulting from the decomposition of ammonia compounds and organic matter. The pharmacopœias avoid this possibility by discontinuing the distillation when 15 per cent. of the water is left in the still.

The material of which the distillatory apparatus used for this purpose is constructed is of considerable importance, but more particularly in relation to the condenser. Iron, copper, and lead condensers must not be used, since the water corrodes these metals, traces and sometimes larger quantities of which will always be found in the distillate. Where a glass condenser is available it may be regarded as the most desirable, apparatus made of metals (silver and platinum) which are not in the least corroded during distillation being too costly for general use. The material best adapted for practical purposes is block-tin, of which the condenser and all those portions of the apparatus should be made from which the vapors are made to descend. A minute quantity of tin is nearly always dissolved, but separates again on standing for a few days in contact with the air. The occasional appearance of *confervæ* in distilled water depends upon its direct contact with the air, and may be prevented by keeping it in vessels arranged in such a manner that the air can enter only after having passed through a layer of cotton, by which the spores are retained.

Properties and Tests.—Distilled water is a colorless, limpid liquid, without odor or taste, and of a neutral reaction. On evaporating 1 liter of distilled water no fixed residue should remain. The transparency or color of distilled water should not be affected by hydrosulphuric acid or sulphide of ammonium (absence of metals), by test solutions of chloride of barium (sulphate), nitrate of silver (chloride), oxalate of ammonium (calcium), or mercuric chloride, with or without the subsequent addition of carbonate of potassium (ammonia and ammonium salts). On heating 100 Ccm. of distilled water acidulated with 10 Ccm. of diluted sulphuric acid to boiling, and adding enough of a dilute solution of permanganate of potassium (1 in 1000) to impart to the liquid a decided rose-red tint, this tint should not be entirely destroyed by boiling for 5 minutes (absence of organic or other oxidizable matters).—*U. S.* Distilled water should not be affected by solution of lime (absence of carbonic acid).—*Br.* On continued exposure to the air distilled water will dissolve carbonic acid gas, and then become cloudy with clear lime-water.

AQUA FÆNICULI, U. S., Br.—FENNEL-WATER.*Eau de fenouil, Fr.; Fenchelwasser, G.*

Preparation.—Oil of Fennel 2 parts (22 grains); Cotton 4 parts (44 grains); Distilled Water a sufficient quantity; to make 1000 parts (25 oz. av. or 24 fluidounces). Add the oil to the cotton in small portions at a time, distributing it thoroughly by picking the cotton apart after each addition; then pack it firmly in a conical percolator, and gradually pour on distilled water until 1000 parts of percolate are obtained.—*U. S.*

Take of bruised fennel 1 pound av.; water sufficient; distil 1 gallon Imperial measure or 10 pounds av. (*Br.*), 30 pounds av. (*P. G.*) If a good fennel is employed the water last mentioned separates a small portion of oil on standing, and is therefore a saturated solution.

Medical Action and Uses.—Fennel-water is stimulant and carminative, and, like its associates, is used as a vehicle for medicines intended to correct *acidity* and relieve *flatulence* and *colic*. *Dose*, 1 drachm (Gm. 4) or more, according to the age of the patient and the degree of the derangement.

AQUA LAUROCERASI, Br.—CHERRY-LAUREL WATER.*Eau distillée de laurier-cerise, Fr.; Kirschlorbeerwasser, G.*

Preparation.—Take of fresh leaves of Cherry Laurel 1 pound; Water 2½ pints (50 ounces). Chop the leaves, crush them in a mortar, and macerate them in the water for 24 hours; then distil 1 pint (20 ounces) of liquid. Shake the product, filter through paper, and preserve it in a stoppered bottle.—*Br.*

To facilitate distillation, Pettenkofer suggests for this water the process recommended by him for bitter-almond water. (See AQUA AMYGDALÆ AMARÆ.) The distillate contains oil of bitter almonds and hydrocyanic acid, and is similar to bitter-almond water; but the British Pharmacopœia does not indicate its strength in hydrocyanic acid. The German Pharmacopœia (1872) required it to be of the same strength as bitter-almond water.

Medical Action and Uses.—This preparation has no virtues which it does not owe exclusively to the hydrocyanic acid it contains. Like all distilled waters, its strength is very uncertain, and it is altogether less eligible than a definite solution of hydrocyanic acid or of oil of bitter almonds in water, not only because its strength is variable, but because the inequality of its effects may lead to disastrous results. The dose is stated to be from 5 to 30 minims (Gm. 0.30–2.00), very cautiously administered.

AQUA MENTHÆ PIPERITÆ, U. S., Br., P. G.—PEPPERMINT-WATER.*Eau de menthe poivrée, Fr.; Pfefferminzwasser, G.*

Preparation.—Oil of Peppermint 2 parts (22 grains); Cotton 4 parts (44 grains); Distilled Water a sufficient quantity; to make 1000 parts (25 oz. av. or 24 fluidounces). Add the oil to the cotton in small portions at a time, distributing it thoroughly by picking the cotton apart after each addition; then pack it firmly in a conical percolator, and gradually pour on distilled water until 1000 parts of percolate are obtained.—*U. S.*

Take of Oil of Peppermint 1½ fluidrachms; Water 1½ gallons; distil 1 gallon (10 pounds).—*Br.*

P. G. distils 10 parts of water from 1 part of the herb; *Fr. Cod.*, 1 part from 1 part of the fresh herb.

Off. Prep.—Mistura ferri aromatica.—*Br.*

Medical Action and Uses.—Peppermint-water is used as a vehicle for many medicines which are unpleasant to the taste or which occasion nausea or griping. It is the most common domestic remedy for flatulent *colic*, and in hot water is frequently resorted to for relief from the pains of *dysmenorrhœa*. Like other diffusible and aromatic stimulants, it palliates *headache*, *pulspitation*, *hiccup*, etc. produced by laborious digestion. *Dose*, half a fluidounce (Gm. 16) or more.

AQUA MENTHÆ VIRIDIS, U. S., Br.—SPEARMINT-WATER.*Eau de menthe verte, Fr.; Römisch-Minzwasser, G.*

Preparation.—Oil of Spearmint 2 parts (22 grains); Cotton 4 parts (44 grains); Distilled Water a sufficient quantity; to make 1000 parts (25 oz. av. or 24 fluidounces). Add the oil to the cotton in small portions at a time, distributing it thoroughly by picking the cotton apart after each addition; then pack it firmly in a conical percolator, and gradually pour on distilled water until 1000 parts of percolate are obtained.—*U. S.*

Take of Oil of Spearmint 1½ fluidrachms; Water 1½ gallons. Distil 1 gallon (10 pounds).—*Br.*

On the continent of Europe curled-mint water is used instead. *Aqua menthæ crispæ*, *P. G.*, is prepared by mixing curled-mint leaves 1 part with sufficient water, and distilling 10 parts.

Medical Action and Uses.—Spearmint-water has the same virtues as peppermint-water, but is much milder in its action. It is particularly appropriate in cases of infantile *colic*, for which it may be prescribed with a little bicarbonate of sodium or magnesia in doses of a teaspoonful. The average *dose* for an adult is half a fluidounce (Gm. 16).

AQUA PIMENTÆ, Br.—PIMENTO-WATER.

Eau de piment de la Jamaïque, Fr.; Nelkenpfeffer-Wasser, G.

Preparation.—Take of Pimento, bruised, 14 ounces; Water 2 gallons. Distil 1 gallon (10 pounds).—*Br.*

On standing it separates a brownish resin.

Medical Action and Uses.—Pimento-water is a stimulant carminative. Its effects are less transient than those of fennel- and anise-water, for example, and more like such as are produced by an infusion of cloves. *Dose*, half an ounce or more for an adult (Gm. 16).

AQUA ROSÆ, U. S., Br., P. G.—ROSE-WATER.

Aqua Rosarum.—Eau distillée de rose, Fr.; Rosenwasser, G.

Preparation.—Recent Pale Rose 40 parts (40 oz. av.); Water 200 parts (200 oz. av.); to make 100 parts (100 oz. av. or 96 fluidounces). Mix them, and by means of steam distil 100 parts.—*U. S.* If preserved by the addition of one-half the weight of table-salt, 60 (instead of 40) parts of such preserved rose-petals should be used.

This is in the proportion of 2 parts of fresh petals to 5 parts of distillate. *Br.* and *Fr. Cod.* direct the distillate to be equal in weight to the petals; *P. G.* 1872 obtained 5 parts of water from 1 part of fresh petals; but in the recent edition it is directed to be prepared by dissolving 4 drops of oil of rose in 1000 Gm. (33.8 fluidounces) of lukewarm water, and when cool filtering.

Off. Prep.—Rose-water is an ingredient of *Confectio rosæ, U. S.*; *Mistura ferri composita, U. S., Br.*; *Trochisci bismuthi, Br.*; *Unguentum aquæ rosæ, U. S.*

Medical Uses.—Rose-water has no strictly medicinal virtues. It is an agreeable excipient for collyria, urethral injections, and lotions.

AQUA SAMBUCI, Br.—ELDERFLOWER-WATER.

Eau distillée de sureau, Fr.; Fliederblumen- (Hollunderblüthen-) Wasser, G.

Preparation.—Take of Fresh Elderflowers, separated from the stalks, 10 pounds (or an equivalent quantity of the flowers preserved while fresh with common salt); Water 2 gallons. Distil 1 gallon (10 pounds).—*Br.*

Elderflowers 1 part; Water sufficient. Distil 10 parts.—*P. G.* 1872.

On standing it is inclined to separate a mucilaginous sediment, which must be removed by filtration.

Medical Uses.—Elderflower-water is used in England as an agreeable excipient for medicines. It possesses no definite virtues. *Dose*, an ounce or more (Gm. 32).

AQUÆ MINERALES.—MINERAL WATERS.

Eaux minérales, Eaux médicinales naturelles, Fr.; Mineralwässer, G.

These are spring-waters which are charged with certain gases or salts to such a degree that they are unfit for ordinary use, and exert a peculiar operation on the economy.

The following summary gives the composition of a few of the most important mineral waters, which may be divided into the following classes:

I. SULPHURETTED WATERS contain sulphides and sulphuretted hydrogen, in consequence of which they possess a more or less fetid odor:

Barèges.—The *Source de l'entrée* contains in 10,000 parts: 0.360 sodium sulphide, 0.219 sodium chloride, 0.240 alkaline carbonates, 0.300 sodium sulphate, and traces of iodine and organic matter (Henry).

Baden (Austria), Leopoldsquelle.—10,000 Gm. contain 0.065 sodium carbonate, 0.800 calcium carbonate, 1.780 sodium sulphate, 3.467 calcium sulphate, 0.610 potassium sulphate, 0.700 magnesium chloride, 0.030 silica, 0.013 magnesium sulphate, 1.705 sodium chloride, 1340.19 Ccm. carbonic acid, 2836.09 nitrogen, 335.19 oxygen, and 232.73 sulphuretted hydrogen (Keller).

Harrington, Old Sulphur Well.—10,000 parts contain 0.26 calcium sulphate, 1.75 calcium carbonate, 11.55 calcium chloride, 7.86 magnesium chloride, 9.14 potassium chloride, 122.38 sodium chloride, 2.19 sodium sulphide, 0.03 silica, and traces of fluoride, bromide, iodide, and carbonate of sodium, calcium, ammonium, iron, and manganese, and organic

matter. Also the following gases in 1 Imperial gallon: 22 cubic inches carbonic acid, 5.3 sulphuretted hydrogen, 5.8 carburetted hydrogen, and 2.9 nitrogen (A. W. Hoffmann).

Massena, St. Regis.—1 U. S. gallon contains 79.692 grains sodium chloride, 0.508 potassium chloride, 29.927 magnesium chloride, 0.673 magnesium bromide, 4.852 calcium bicarbonate, 0.488 ferrous bicarbonate, 60.931 calcium sulphate, 3.501 sodium sulphate, 1.320 sodium phosphate, 4.205 sodium hyposulphite, 1.405 sodium sulphide, 11.176 sodium silicate, and organic matter; total, 198.678 grains, and 5.307 cubic inches of sulphuretted hydrogen (F. F. Mayer).

2. ALKALINE WATERS.—Carbonate of sodium predominates, and free carbonic acid is often present in considerable quantity:

Enns, Kreinchen.—10,000 parts contain the following carbonates: 13.651 sodium, 1.559 calcium, 1.292 magnesium, 0.016 iron, 0.007 manganese, 0.001 barium; 9.224 sodium chloride, 0.004 phosphate of aluminium, 0.494 silica, traces of iodide of sodium and carbonate of lithium, and 9991 Cem. carbonic acid (Fresenius).

Vichy, Source Lucas.—10,000 parts contain the following bicarbonates: 50.04 sodium, 2.82 potassium, 2.75 magnesium, 0.05 strontium, 5.45 calcium, and 0.04 iron; 2.91 sodium sulphate, 0.70 sodium phosphate, 0.02 sodium arseniate, 5.18 sodium chloride, 0.50 silica, and 17.51 carbonic acid; total solids, 70.46 (Bouquet).

The water of the Grande Grille spring has nearly the same composition with 70.33 solids, but contains only 9.08 parts of carbonic acid. Tichborne found in 16 ounces of the bottled water 44.408 grains of solids.

Gettysburg.—1 Imperial gallon contains 46.05 grains bicarbonate of sodium, with lithium, 76.05 magnesium bicarbonate, 81.00 calcium bicarbonate, 53.20 calcium sulphate, 10.00 silica, with traces of potassium and iron chlorides and phosphates; total, 266.30 grains (Mayer).

3. SALINE WATERS contain various salts of alkalies and alkaline earths, occasionally bromides and iodides. Dieulafoy (1881) believes that the saline waters of Western Europe are mineralized in the salt-bearing strata of the Trias and Tertiary formation, and that the mineralizing compounds were formerly contained in ordinary seas, and have been deposited by simple evaporation.

Bedford Springs, Pa.—1 pint contains calcium sulphate 11.274 grains, magnesium sulphate 3.974 grs., aluminium and iron sulphates 1.280 grs., sodium sulphate 3.092 grs., sodium chloride 0.343 gr., calcium carbonate 2.120 grs., sulphuric acid (?) 0.128 gr., organic matter and silica trace (J. C. Morris).

Cheltenham, Royal Old Wells.—10,000 parts contain 34.202 sodium chloride, 1.141 magnesium chloride, 13.541 sodium sulphate, 0.970 magnesium carbonate, 2.433 calcium carbonate, 0.436 magnesium bromide, 0.069 magnesium iodide, 0.381 silica, 1.473 crenic acid, 2.574 organic matter, and 92 Cem. carbonic acid (Abel and Rowney).

Carlsbad (Bohemia), Sprudel.—10,000 parts contain 24.05 sodium sulphate, 18.612 sodium bicarbonate, 10.223 sodium chloride, 4.638 calcium bicarbonate, 2.537 magnesium bicarbonate, 1.862 potassium sulphate, .141 lithium chloride, .715 silica, .051 sodium fluoride, .041 ferrous bicarbonate, .040 sodium borate, and much smaller quantities of sodium phosphate, strontium, manganese, and alumina, besides carbonic acid; total solids, 62.928 (Ludwig). The numerous other Carlsbad springs analyzed by Ludwig (1879) have a similar composition, the total solids decreasing to 60.798 parts in the water of the *Schlossbrunnen*.

Friedrichshall (Saxe-Meiningen) Bitter-water.—16 ounces contain 61.102 sodium chloride, 46.510 sodium sulphate, 39.533 magnesium sulphate, 30.252 magnesium chloride, 3.992 magnesium carbonate, .876 magnesium bromide, 1.523 potassium sulphate, 10.341 calcium sulphate, .113 calcium carbonate; total salts, 194.242 grains; carbonic acid 5.322 cubic inches (Liebig). The bottled water contains in 16 ounces 99.722 grains sodium chloride, 71.535 sodium sulphate, 64.138 magnesium sulphate, 50.114 magnesium chloride, 2.102 magnesium carbonate, .275 magnesium bromide, 2.518 potassium sulphate, 17.130 calcium sulphate, .440 silica; solids, 307.974 grains, and carbonic acid (Tichborne).

Hunyadi János.—16 ounces of the bottled water contain free carbonic acid and 337.066 grains of solids, consisting of 157.957 sodium sulphate, 156.350 magnesium sulphate, .716 potassium sulphate, 10.531 sodium chloride, 6.051 calcium carbonate, 5.152 sodium carbonate, .20 strontium carbonate, and .029 iron and alumina (Tichborne).

Schlitz.—16 ounces contain 104 grains sulphate, 3 grains carbonate, and 3 grains chloride of magnesium, 8 grains carbonate and 8 grains sulphate of calcium; total, 126 grains (Naumann).

4. ACIDULOUS SALINE WATERS contain various salts and are sparkling from the large amount of carbonic acid contained in them:

Neuenahr, Apollinaris.—16 ounces of the bottled water contain free carbonic acid and 25.868 grains of salts, consisting of 10.621 sodium bicarbonate, 5.023 sodium chloride, 2.402 sodium sulphate, .141 potassium sulphate, 4.50 magnesium carbonate, 2.880 calcium carbonate, .10 ferric oxide, .080 alumina, .121 silica, and traces of sodium phosphate, lithium, ammonia, and nitric acid (Tiechborne).

Grosskarben, Taunus.—16 ounces of the bottled water contain 32.403 grains of free carbonic acid and 31.262 grains of solids, consisting of 18.004 sodium chloride, 1.890 potassium chloride, 9.590 calcium carbonate, 1.232 magnesium carbonate, .140 sodium carbonate, .406 calcium sulphate, and traces of calcium phosphate, silica, and alumina (Taylor, Tiechborne).

Pyrmont, Hauptquelle.—160 ounces contain the following sulphates: 0.023 grain barium, 0.280 strontium, 60.897 calcium, 1.266 potassium, 3.220 sodium, and 34.813 magnesium; the following chlorides: 12.202 sodium, 0.161 ammonium, and 0.076 lithium; the following bicarbonates: 86.832 calcium, 6.160 magnesium, 5.919 iron, and 0.344 manganese; 0.001 sodium iodide, 0.007 sodium bromide, 0.012 sodium nitrate, 0.006 aluminium phosphate, 0.004 calcium phosphate, 2.441 silica, 183.956 grains carbonic acid, and a trace of sulphuretted hydrogen (Fresenius).

Selters.—16 ounces contain 0.248 grain sodium sulphate, 16.285 sodium chloride, 5.855 sodium carbonate, 1.595 magnesium carbonate, 1.867 calcium carbonate, 0.154 ferrous carbonate, 0.281 sodium phosphate, 0.289 silica, and 31 cubic inches carbonic acid (Bischof).

Saratoga, Empire Spring.—1 U. S. gallon contains 506.63 grains sodium chloride, 4.292 potassium chloride, 0.266 sodium bromide, 0.006 sodium iodide, 2.769 potassium sulphate, 0.023 sodium phosphate, 1.458 silica, 0.418 alumina, with the following bicarbonates: 42.953 magnesium, 109.656 calcium, 2.080 lithium, 9.022 sodium, 0.070 barium, 0.793 iron, and trace of strontium; also traces of calcium fluoride, borax, and organic matters; total, 680.436 grains, and 344.67 cubic inches carbonic acid (Chandler and Cairns).

The acidulous saline waters of the numerous other springs of Saratoga have a similar composition; in the following table they are arranged according to the abundance of carbonic acid gas, in addition to which we give, in grains, the total solids and the weight of the most important saline constituents contained in one gallon:

Name.	CO ₂ , cub. inch.	Total solids.	NaCl.	NaHCO ₃ .	MgO(CO ₂) ₂ .	CaO(CO ₂) ₂ .	FeO(CO ₂) ₂ .	LiHCO ₃ .

The temperature of these springs is between 45° F. (Washington) and 52° F. (High Rock and Star); the water of the Kissingen springs is 40° F.

Whitehall (N. Y.) Adirondack Springs.—1 Imperial gallon contains 14.340 grains sodium chloride, 11.134 calcium sulphate, 18.543 calcium carbonate, 16.618 magnesium carbonate, 5.040 ferrous carbonate, 5.317 potassium carbonate, 5.135 sodium carbonate, 0.023 lithium carbonate, traces of magnesium carbonate and alumina, 7.42 insoluble residue, and 67.3 cubic inches of carbonic acid (Collier).

Kissingen, Rakoczy.—16 ounces contain 0.242 grain ferrous carbonate, 0.131 magnesium carbonate, 8.148 calcium carbonate, 0.043 calcium phosphate, 0.099 silica, 2.990 calcium sulphate, 44.713 sodium chloride, 4.509 magnesium sulphate, 2.203 potassium chloride,

2.333 magnesium chloride, 0.064 sodium bromide, 0.071 sodium nitrate, 0.153 lithium chloride, 0.007 ammonium carbonate; total, 65.706 grains, and 41.77 cubic inches of carbonic acid (Liebig).

5. **CHALYBEATE WATERS.**—This name is applied to those mineral waters which contain iron in sufficient quantity to impart to them a ferruginous taste. The iron is present either as sulphate or frequently as ferrous carbonate, held in solution by excess of carbonic acid, sulphuretted hydrogen being also occasionally present. Iron being found in several of the waters named before in larger quantities than mere traces, it is evident that the classification must be somewhat arbitrary.

Homburg, Stahlbrunnen.—16 ounces contain 0.937 ferrous carbonate, 7.534 calcium carbonate, 10.667 calcium chloride, 5.330 magnesium chloride, 79.864 sodium chloride, 0.176 potassium sulphate, 0.146 calcium sulphate, 0.315 silica; total, 104.969 grains, and 46.90 cubic inches carbonic acid (Liebig).

Spa, Source du Pouton.—10,000 parts contain the following bicarbonates: 1.266 sodium, 0.105 potassium, 1.730 calcium, 1.674 magnesium, and 0.714 iron; 0.203 sodium sulphate, 0.256 sodium chloride, 0.629 silica, and 21.409 carbonic acid (Plateau).

Pymont, Trinkquelle.—16 ounces contain 0.490 ferrous carbonate, 1.126 magnesium chloride, 0.323 magnesium carbonate, 0.048 manganium carbonate, 5.988 calcium carbonate, 0.014 aluminium phosphate, 0.496 silica; and the following sulphates: 2.697 magnesium, 7.221 calcium, 0.020 strontium, 0.009 lithium, 0.042 potassium, and 2.145 sodium; total, 20.619 grains, and 1.68 volumes of carbonic acid (Struve).

Cheltenham (chalybeate).—1000 parts contain 0.066 ferrous carbonate, 0.159 calcium carbonate, 0.735 calcium chloride, 0.484 magnesium chloride, 0.390 potassium chloride, 2.262 sodium chloride, 0.020 silica, 0.040 organic matter; total, 4.156. 1 gallon contains also 19.5 cubic inches carbonic acid and 5 cubic inches carburetted hydrogen (A. W. Hofmann).

Church Hill Alum-Water.—1 U. S. gallon contains 24.991 grains ferrous sulphate, 51.270 ferric sulphate (neutral), 83.355 ferric sulphate (one-third basic), 72.928 aluminium sulphate, 86.064 magnesium sulphate, 88.836 calcium sulphate, 0.643 ammonium sulphate, 2.444 potassium sulphate, 1.943 sodium sulphate, 4.627 sodium chloride, 10.429 silica, and a trace of phosphoric acid; total, 427.530 grains (J. C. Booth).

6. **THERMAL SPRINGS.**—Their temperature is above that of the locality in which they are situated, and they serve an important use for baths, although most of these waters are also used internally. In the following we give some of the best known, arranged according to their temperature:

Carlsbad, Sprudel.—Temperature 73.5° C. (172.4° F.). (See above, under SALINE WATERS.) The temperature of eight other hot springs ranges between 60.2° and 43° C. (140.4° and 109.4° F.), and the average amount of solids is 61.966 in 10,000 parts.

Wiesbaden, Kochbrunnen.—Temperature 68.8° C. (155.8° F.). 10,000 parts of the water contain 68.356 sodium chloride, 1.458 potassium chloride, .002 lithium chloride, .167 ammonium chloride, 4.710 calcium chloride, 2.039 magnesium chloride, .035 magnesium bromide, .902 calcium sulphate, .004 calcium phosphate, 4.180 calcium carbonate, .104 magnesium carbonate, .056 ferrous carbonate, .006 manganum carbonate, .001 calcium arseniate, .604 silica and alumina, and .34 volumes carbonic acid; total solids, 82.624 (Presenius). The temperature of other springs ranges from 66° to 49.5° C. (150.8° to 120.2° F.).

Baden-Baden.—The temperature of nine springs ranges between 68.63° and 44.4° C. (156° and 112° F.), and the solid constituents of 10,000 parts between 29.528 and 27.0213, of which between 22.244 and 18.892 parts are sodium chloride.

Hot Springs, Arkansas.—The fifty-seven springs range in temperature between 65.5° and 33.9° C. (150° and 93° F.); the solid constituents amount to a little over a grain in the pint.

Aix-la-Chapelle (Aachen).—Four springs range in temperature between 55° and 45.4° C. (131° and 113.7° F.), and the solids in 10,000 parts between 44.4815 and 40.1446, of which 60 per cent. is sodium chloride and 20 per cent. sodium bicarbonate.

Bath, King's Spring.—Temperature 46.2° C. (115° F.). 10,000 parts contain 20.597 solids, consisting of 11.425 calcium sulphate, 0.662 potassium sulphate, 2.744 sodium sulphate, 1.259 calcium carbonate, 0.047 magnesium carbonate, 0.152 ferrous carbonate, 1.802 sodium chloride, 2.081 magnesium chloride, 0.425 silica, with traces of lithia, manganese, and iodine; carbonic acid not determined (Merck and Galloway).

Gastein, Wildbad.—Temperature 49° to 25° C. (120.2° to 77° F.); salts, 3.483 in 10,000 parts.

Ems.—Thirteen springs range in temperature between 46.64° and 27.9° C. (116° and

82.2° F.). 10,000 parts of water contain 31.74 to 38.194 solids, mostly carbonates with chlorides.

Idaho Springs, Colorado.—Range of temperature 46.1° to 29.5° C. (115° to 85° F.). A gallon contains 107 grains of salts, mostly sulphates with carbonates.

Vichy.—Eight springs range in temperature between 43.5° and 22° C. (108.5° and 71.6° F.). (See above, under ALKALINE WATERS.)

Hot Springs, Virginia.—Temperature between 43.3° and 25.5° C. (110° and 78° F.). A gallon of water contains 18 to 33 grains of salts, mostly carbonates with chlorides and sulphates.

ARTIFICIAL MINERAL WATERS have been manufactured and used for many years both in Europe and the United States; many of these are close imitations of the natural waters. Works giving instructions on the manufacture of such waters have been published by (among others) Dr. H. Hager, Dr. Græger, and recently (1883) by Dr. F. Raspe. We append here a few formulas which have been recommended as yielding tolerably good substitutes for the waters of the springs named:

Baden (chalybeate).—Chloride of sodium 28 grains, chloride of magnesium 2 grains, chloride of calcium 13 grains, sulphate of sodium 11.5 grains, tartrate of iron and potassium $\frac{1}{2}$ grain, water 21 fluidounces; dissolve and impregnate with carbonic acid gas (Soubeiran).

Carlsbad.—Sulphate of sodium 54 grains, sulphate of magnesium 5 $\frac{1}{2}$ grains, carbonate of sodium 36 $\frac{3}{4}$ grains, chloride of sodium 7 grains, chloride of calcium 7 grains, tartrate of potassium and iron $\frac{1}{2}$ grain, water 21 fluidounces; proceed as before (Soubeiran).

Seidlitz.—Sulphate of magnesium 7 $\frac{1}{2}$ drachms, water 22 fluidounces; proceed as before; or

Dissolve 7 $\frac{1}{2}$ drachms sulphate of magnesium and 1 drachm of bicarbonate of sodium in 22 fluidounces of water; add 1 drachm of crystallized tartaric acid, and cork the bottle well (*Fr. Cod.*).

Sulphur-water (to imitate *Barèges, St. Sauveur*, etc.).—Crystallized sulphide of sodium and chloride of sodium 2 grains, water previously boiled to deprive it of air 22 fluidounces; dissolve (*Fr. Cod.*).

Vichy.—Carbonate of sodium 112 grains, carbonate of potassium 2 $\frac{1}{2}$ grains, sulphate of magnesium 5 grains, fused chloride of calcium 4 $\frac{1}{2}$ grains, chloride of sodium 1 $\frac{1}{2}$ grains, arseniate of sodium $\frac{1}{32}$ grain, powdered iron $\frac{1}{63}$ grain, water 21 fluidounces; dissolve and impregnate with carbonic acid gas (Lefort).

Physiological Action.—The use of spring-waters more or less impregnated with substances imbibed by them in the bowels of the earth has existed in all ages. A knowledge of their virtues, as of many other useful medicines, was very probably learned by observing the instinctive use of them by the lower animals. Tradition runs that some of the most famous of German springs owe their reputation originally to their use by sick animals, and that others were eagerly visited by the kine at certain seasons of the year. It is certain that our own Saratoga, which is now annually crowded by gay votaries of fashion as well as by the dejected victims of a morbid civilization, was long resorted to by the aboriginal savages for the cure of their infirmities. In ancient Greece temples were in many places erected near mineral springs, whose waters were used under the direction of the priests, who thus became the earliest physicians, and who taught that hygiene and medicine must go hand in hand, and proved that faith has no small share in the cure of disease. But the "scientific medicine" of the present day treats the human body as if it were so much brute matter to be subjected to analytical and synthetical reagents for the purpose of evolving definite results; the true physician, on the other hand, never neglects the vital and physical elements of man, and sagaciously enlists in behalf of his patients all the powers of external nature as well as the quickening influences of faith and hope. Formerly, mineral waters could be made use of by those persons only who were able to visit the springs, but now they are carried to great distances, and even across the ocean, for those who require them; their saline residue, after evaporation of the water, has equally become an article of commerce; and chemical ingenuity has imitated the solid constituents of the most important springs, without, however, securing the effects produced by the natural combinations.

Attempts to explain the action of medicines exclusively by scientific methods have not resulted satisfactorily. Upon this subject we are entirely in accord with Trousseau, who addressed his clinical class in these words: "Distrust medical theories that originate in the laboratory. Although Chemistry may be the handmaid of Medicine, she goes beyond her sphere when she applies the conclusions of the laboratory to the treatment of the

sick. Chemistry stands no nearer to Medicine because she teaches us how to prepare or to analyze medicines, than she does to the art of painting because she prepares the painter's colors. . . . Say what the chemists may, mineral waters do not operate alone by means of their predominant mineral constituent. It is associated with many others which they have demonstrated, and probably with others still that have escaped their research; and nature has done for this element what we attempt every day to do in pharmacy when we seek to enhance or to mitigate the power of a medicine by associating it with others." Then, referring to the well-known fact that the therapeutical reputation and efficacy of mineral waters do not depend upon the amount of their mineral constituents, this sagacious teacher in substance observed: "The *malarial cachexia*, for instance, is wonderfully modified by springs whose mineral elements really elude discovery, and are far less than those which impregnate the drinking-water of Paris; and certain intractable dyspeptic disorders are cured by them in a manner which I neither can nor seek to explain. Under their salutary influence the appetite revives, the constitution becomes reorganized; patients affected with dropsy or visceral engorgements arrive at Plombières or Bigorre in a deplorable condition, and after a single season have been greatly improved and often most unexpectedly cured." Even anciently it was understood that the medicinal virtues of a spring do not depend altogether upon the degree of its mineralization, for Pliny refers to the Paduan waters as having neither taste nor smell. It would, however, be unjust to these natural medicines to suppose that they are not, on the whole, valuable in proportion to their mineralization; indeed, we may go further, and measure and define their value by the proportion of their predominant ingredient, be it saline, alkaline, sulphurous, or chalybeate, for if we subtract this one element the special virtues of the water vanish. On the other hand, it is notorious that the medicinal use of such elements isolated from their natural associations no longer produce the effects of the original mineral waters. In these facts again we perceive the excellency of nature and the insufficiency of self-sufficient art.

There are, indeed, two classes of patients who require the use of very different mineral waters. The first is composed of that large body of invalids in whom there exists no organic change of structure, but whose functions are merely weakened or clogged by the strain of business, the exhaustion of pleasure, sensual excesses in eating or drinking, or, in this country especially, by the manifold errors committed in the preparation and consumption of food and the disregard of hygienic rules in their habits of living. The second consists of that smaller but still numerous class of persons who, besides being more or less injured by the causes of ill-health just enumerated, have been affected with definite diseases, and especially rheumatism, gout, calculous disorders, cutaneous eruptions, scrofula, syphilis, diabetes, paralysis, uterine disorders, etc. Of these two classes, the former are benefited most by a visit to the less mineralized springs, while the latter require a course of active medicinal treatment such as the stronger mineral waters afford. In both classes of patients, but particularly in the first, the action of the waters is only one out of many influences that combine to restore their health. Toward that end a total change of habits is one of the most influential agencies in very many cases. Escape from the anxieties and fatigue of business, from the excitement of fashionable life, the mental tension of political and professional pursuits, the worrying annoyances of domestic affairs, endured perhaps in a large city with all its enervating social duties, its Babel-like sounds, and its polluted atmosphere,—escape from these alone ought to suffice to restore the disturbed balance of health. When we consider how much more probable must this result become when fatigue, anxiety, contention, wearisome routine, and foul air are exchanged for repose and peace in the midst of novel scenes and new associates and freedom from the onerous conventionalities of fashionable life, different apartments, food, and occupation, it may even seem doubtful whether, after all, some other new residence would not profit the invalid as much as the frequented springs. But there are two reasons against this conclusion: the one is, that with many persons relief would be impossible without an exercise of the faith which gives potency to waters as well as to other remedial agents; and the other is, that even the purest of these waters, systematically used, especially in conjunction with bathing and regular exercise, do in a greater or less degree deplete the system through the kidneys, bowels, and skin, and by a gentle but sustained action gradually remove the effete products of tissue-change from the system and free the organs from the burdens that oppressed and the poisons that tainted them. Judiciously used under the advice of a competent physician, these almost neutral waters and the milder saline springs are capable in a few weeks of changing the languid, indifferent, pale, and feeble invalid into the lively and energetic leader of the gay crowd. Such rapid transformations are frequently witnessed, especially at the hot springs of Virginia and certain

European springs, such as Wildbad, Gastein, and Pfeffers, none of which contain any considerable proportion of mineral ingredients. But these waters, whether drunk warm or cold, if they are largely used act as organic purgatives, and increase materially the total amount of solids, and especially of urea, excreted with the urine, without causing the debility which an equal discharge from the bowels would occasion.

Waters of the other class, rich in mineral ingredients, have a more direct relation to certain special forms of disease. Alkaline waters, for example, are particularly adapted to the treatment of *gout* and *rheumatism*; sulphurous waters to that of the same diseases and of *scaly eruptions* of the skin; ferruginous waters to the cure of *anæmic* disorders; salines, to that of chronic *dyspepsia*, *constipation*, *hæmorrhoids*, etc. But as these several waters are classed only according to their predominant ingredient, and each one contains several others of real even if of secondary importance, it is evident, as before intimated, that neither their physiological nor their curative operation can be regarded as the effect of only one of their constituents, although it may happen to be the principal one. Moreover, it cannot be assumed that the same water or class of waters has but a single mode of action; for, although it is probably true that alkaline waters cure both gout and rheumatism in virtue of their alkalinity, yet sulphurous waters which cure rheumatism, but do not cure gout, must necessarily produce their effect in a different manner. It is evident, therefore, that while it may be possible to determine a certain scientific relation between particular mineral waters and the diseases they generally relieve, we are as far from comprehending their *modus operandi* as we are from understanding the actions of mercury, iodine, opium, quinia, or colchicum in the several conditions which they palliate or cure.

The temperature at which mineral waters are used materially influences their effects, whether they are taken internally or employed as baths. Indeed, as above stated, some hot springs which have for ages maintained their fame are but faintly or not at all mineralized; but there is hardly an instance of a cold spring destitute of active medicinal properties that enjoys much credit as a medicine. The operation of warm and hot water is described elsewhere. The highest reputation belongs, perhaps, to those mineral waters which are both hot and strong, and which modify nutrition in every part and quicken depuration through the bowels, the kidneys, and the skin. The energy with which they act is shown by the occurrence of phenomena which are known as “*crises*” when they are caused by the internal use of thermal waters, and as the “*bath fever*” when due to their external application. Both have in common a feverish condition, attended by languor, debility, and lightness of the head—symptoms which appear to be due to a rapid and excessive loss of tissue, for they are identical with the effects of over-fatigue. When this state is induced by bathing it is usually accompanied with papular, vesicular, or erythematous eruptions upon the skin, which may be ascribed in part to the copious sweating induced, but partly also to the irritating action of the caloric and of the mineral elements of the waters.

It may be proper to add that the use of mineral waters by persons suffering from organic heart disease, obstruction of the glandular portion of the kidneys (Bright's disease), a tendency to cerebral disease, the advanced stages of pulmonary consumption, etc., should be very cautiously advised and very watchfully conducted.

Medical Uses.—To describe with any detail the application of mineral waters to the cure of diseases is here impossible; we shall only endeavor to sketch an outline of the subject, which is deserving of far more attention than it generally receives:

1. *Sulphur-Waters.*—Their virtues vary greatly according to the qualities of the waters themselves, and particularly according to their purgative action and their internal or external use. That they affect the whole system is proved by the elimination of sulphuretted hydrogen during their use, so that silver articles worn near the skin are blackened. They differ from other mineral waters in having a sedative operation when applied externally, especially when their sulphurous element exceeds their saline or calcareous in energy. They are employed in a great variety of disorders, both internally and externally. The more purgative varieties have a great vogue in almost all forms of chronic *dyspepsia*, but especially in those which result from high living and are attended with congestion of the liver, constipation, and jaundice. In such cases the non-purgative sulphur-waters are more injurious than useful, causing plethora and its consequences. Indeed, the dyspeptic cases held to be profited by these waters are much more so by the non-sulphurous salines. Sulphurous waters, on the other hand, are more useful in chronic *skin diseases*, including eczema, psoriasis, pityriasis, lichen, and acne, and they are most so when used in baths. Their internal use, apart from special indications, is superfluous.

Such indications may be presented by *scrofula*, especially of the glandular sort, in which a long-continued but moderate use of the waters is most profitable. In this affection the baths should be prolonged as much as possible. When *gout* is connected with the above conditions these waters are less serviceable than the saline and alkaline. Probably, in the cure of chronic *rheumatism* more than in that of any other disease sulphur-waters stand pre-eminent—in the muscular forms first, and in the articular less conspicuously. They probably act as diaphoretics and diuretics, and hence as eliminants, when taken internally; while in warm baths, which is the best mode of using them, they both promote elimination and by their local action remove the pain, swelling, and stiffness of the joints. The hotels at sulphur springs often contain museums of crutches, wheel-chairs, etc. left behind by patients who arrived as cripples and departed with supple limbs. In ancient times such articles would have formed *ex-voto* offerings in the temples. As *syphilis* is a specific poison in the system, it might be supposed that the searching operation of sulphur-waters, in their several modes of application, would tend to remove it, but such is seldom the result; and, indeed, very often the use of these waters revives the signs of the disease in persons who had been regarded as entirely cured. On the other hand, when there is a cachectic condition present, induced by an excessive mercurial treatment, such waters may greatly contribute to improve the health. *Lead-poisoning*, it is well known, in its chronic and constitutional forms, is more successfully treated by sulphur-baths than by any other agent except iodide of potassium. They form a most important adjuvant to the latter medicine. Their utility in *paralysis* will depend upon its nature, as whether it be of central origin with substantial lesions, or due to imperfect nutrition, or else wholly peripheral. In the first they can only be adjuvants; in the other cases they may effect a cure. But it is probable that they act in no other way than by promoting the general health through their internal use, and stimulating the paralyzed muscles externally in the same way as friction, electricity, etc. In paralysis following cerebral or spinal apoplexy there is great danger in using thermal sulphur-waters to excess. Of local diseases for which the waters are useful may be mentioned—first, chronic *pharyngitis*, especially of that granular form, which is so often associated with dyspepsia, and was formerly known as “clergyman’s sore throat.” Saline sulphur-waters internally and applied locally by atomization are very successful in relieving it. The same may be said of chronic *bronchitis*, especially when it occurs in gouty or rheumatic persons and with dilatation of the bronchia, and in a less degree of chronic *laryngitis* of the simple form. Yet the tubercular and the syphilitic forms may sometimes be improved by them. Sulphur-waters have been much used in diseases of the uterine system, especially in *sterility*, *amenorrhœa*, and *leucorrhœa*; but little is to be expected from them in such affections unless they are used as baths, warm or cold according to the patient’s condition. The feebler sulphur-waters, if they contain iron, may be drunk with advantage. Finally, sulphur-waters are useful in various *surgical diseases*, but chiefly waters of the thermal variety, which operate by their heat rather than by the sulphurous compounds they contain. It may be admitted, however, that the latter elements increase their stimulating power.

2. *Alkaline Waters*.—The dominant part which the chemical reaction of the animal humors plays in vital processes explains the extraordinary potency of alkaline, and in some degree of saline, mineral waters; for the functions of digestion, respiration, etc. depend in a great measure upon the relative amount of acidity or alkalinity of the animal fluids. Alkaline mineral waters, then, may be used so as to neutralize or diminish this acidity, and thereby produce a corresponding change in the physiological action. In point of fact, these waters have long been known as the most efficient in chronic gout and rheumatism and the numerous disorders which depend on them; and the form of *dyspepsia* most successfully treated by their use is attended with excessive acidity of the gastrointestinal secretions, with sour or rancid eructations and regurgitations, flatulent distension of the abdomen, tenderness of the epigastrium, etc.; and all the more so if it is connected with a gouty diathesis. The waters are most efficient when they are highly charged with carbonic acid gas. If there is gastric irritability they must be taken in small doses. *Skin diseases* are not favorably influenced by alkaline waters internally or in baths, and the same is true of *scrofula*. Among all the known alkaline springs, there is only one which can be regarded as pre-eminently curative in *gout*, and that is at Vichy in France. The waters are most usefully as well as conveniently employed internally, but care must be taken not to drink of them too copiously, lest plethoric phenomena arise, nor to run the risk of impoverishing the blood by using them for too long at a time. In this country there is no alkaline spring, properly so called; the nearest approach

to belonging to the category of such springs is made by the St. Louis Spring, Mich., but its water contains only 7.684 grains of carbonate of sodium to the pint, while the Grande Grille Spring at Vichy contains nearly three times as much. Moreover, the former spring holds carbonate and sulphate of lime in large amount, while the latter contains a very small proportion of the former, and of the latter none at all. *Gastralgia*, occurring paroxysmally, is reputed to be frequently cured by these waters taken hot and in the intervals between the paroxysms. It may be doubted whether the heat does not act curatively—as much, at least, as the mineral constituents of the water. Certainly, solutions of bicarbonate of sodium will not relieve gastralgia unless great acidity of the stomach is also present. In chronic *rheumatism* (which is the only form of rheumatism in which the medication by alkaline mineral waters can conveniently be tried), whether muscular or articular, alkaline waters are very highly esteemed, but they are chiefly used in warm baths. No doubt can exist in regard to the efficacy of alkaline waters in removing the symptoms of *gall-stones*. Some persons suppose that these concretions are dissolved by the waters, but of this there is no proof whatever. Others believe that the bile itself is rendered more watery by their use. It is certain that the salts of Vichy and of Carlsbad waters even in this country relieve the symptoms of this affection, provided they are administered in hot water and so as to represent nearly the strength of the natural springs. In the treatment of acid *urinary concretions* and their effects alkaline waters are of great value. They operate as diuretics, and also by neutralizing the excessive acidity of the urine. In the former way they often cause a copious discharge of acid sand. By removing the chief cause of irritation in the urinary passages they tend to cure the catarrh which may affect their mucous membrane. The usefulness of alkaline waters in *diabetes* does not admit of any doubt, however difficult it may be to explain their mode of action. It has been remarked that they are more efficacious when the patient is stout than when he is thin. In favorable examples the progress of the disease may be stayed by them for years. But “diabetes mellitus is an incurable disease,” even by Carlsbad water. (See Mayer, *Med. Record*, xvii. 120.)

3. *Alkaline-saline* mineral waters, which form some of the most famous European springs, including those of Carlsbad, are represented in this country chiefly by the Gettysburg Spring, Pa., the St. Louis Spring, Mich., Capon Springs, Va., Sheldon Springs, Vt., and several in California. They are more or less purgative and diuretic, and are used with great advantage in the same diseases for which alkaline waters proper are employed, but especially in chronic *dyspepsia*, disorder of the *liver*, *gall-stones*, *gout*, *rheumatism*, *gravel*, and morbid *mental* conditions associated with digestive derangements. They are very useful in *uterine* engorgements and *irritability*. They are palliatives of saccharine *diabetes* and of *Bright's disease*, especially those of them which contain a considerable proportion of iron; they have also some repute in the treatment of chronic inflammation of the *pharynx* and *larynx*. According to the purpose for which they are used, the dose should be large or small—the former when a purgative operation is desired, the latter when an alterative action is sought. In the laryngeal and pharyngeal affections named these waters are very useful in the form of an atomized spray.

4. *Acidulous saline* waters are employed in almost the same diseases as the last-mentioned class. Their usefulness is notably increased by the carbonic acid gas with which many of them are charged, and which serves to mask the taste of the sulphates of sodium and magnesium or of the chloride of sodium which they contain, and to make them more acceptable to the stomach. Their mode of action is through a gradual elimination of the accumulated tissue-waste, and the increased activity which is thereby communicated to the whole glandular system. The most celebrated of American springs of this class are those of Saratoga. They are said to attract more than eighty thousand persons annually. Although they are not identical in composition, they differ so little from one another as to exert essentially the same influence on the system. It is so far from negative or indifferent that the use of such waters at unseasonable times and in improper quantities, and by persons who do not need them at all, has been the cause of incalculable mischief. Every one who requires them is also in need of judicious advice in using them. This is seldom to be obtained from the resident physicians or from those who are casual visitors. On the continent of Europe every mineral spring is provided with one or several physicians who are entitled by their knowledge and skill, as well as by their official station, to give wholesome advice regarding the use of the waters. Medical advisers of like competency are greatly needed at the popular watering-places of this country.

5. *Chalybeate* mineral waters are the best representatives of ferruginous medicines.

because they not only enter the system more readily, and therefore improve the blood more rapidly, than artificial preparations of iron, but because the hygienic conditions attending their use are of the most salutary effect. When they contain sulphate of iron (as in the Rockbridge Alum Springs and several others in Virginia) they are especially serviceable in profluvia, as chronic *diarrhœa*, *dysentery*, *diabetes*, *bronchorrhœa*, *leucorrhœa*, etc.

ARALIA.—ARALIA.

Aralie, Fr., G.

Nat. Ord.—*Araliaceæ*.

The following plants have been employed:

1. *ARALIA NUDICAULIS*, *Linné*, *U. S.* 1870.—False or wild sarsaparilla, Small spike-nard, Wild liquorice, *E.*; Racine d'aralie à tige nue, Petit nard, *Fr.*; Naekte Aralien-wurzel, *G.*—It is a perennial plant indigenous to Canada and the United States, where it grows in rich and rocky woodlands as far south as Carolina and Tennessee. The rhizome sends up a single petiole about 12 inches (30 Cm.) long and three-parted at the summit, each division bearing five ovate or oval-serrate and subsessile leaflets. The scape is about 6 inches (15 Cm.) high, and divided into three or five peduncles, each about 2 inches (5 Cm.) long and bearing a globose umbel of many greenish flowers. The rhizome, which is the part employed, is several feet long, horizontal, with some slender branches, and sparingly beset with a few radicles. The internodes are indistinct and the undeveloped buds alternate. The dry rhizome is about $\frac{1}{4}$ inch (6 Mm.) in diameter; the few scape-scars are shallow, cup-shaped, and approximate at the upper annulated end of the branches; the bark is longitudinally wrinkled, of a somewhat glossy pale brownish-gray color externally, the corky layer being easily removed from the white inner bark, which does not firmly adhere to the cylindrical wood. The latter is about $\frac{1}{8}$ inch (3 Mm.) in diameter, of a yellowish color, and encloses a spongy white amylaceous pith. The rhizome breaks with a short fracture, is somewhat aromatic, and has a mawkish taste.

2. *ARALIA RACEMOSA*, *Linné*.—American spikenard, Spignet, Pettymorrel, *E.*; Nard américain, *Fr.*; Amerikanische Narde, *G.*—This plant grows in rich and rocky woods in Canada and the United States. It has an herbaceous stem about 40 inches (1 M.) high, and ternately and quinately divided leaves with ovate or heart-ovate doubly serrate leaflets; the flowers are in small umbels arranged in branching racemes. The rhizome with the roots was, like the preceding drug, formerly known as *Nardus americanus*. The rhizome is oblique, 4 to 6 inches (10 to 15 Cm.) long, and half as wide; the nodes are approximate, and the stem-scars prominent, about 1 to 1½ inches (25 to 38 Mm.) in diameter, the older ones deeply concave. The roots are numerous, from 20 to 30 inches (50 to 75 Cm.) long, about 1 inch (25 Mm.) or more thick near the rhizome, and little branched below. It has a stronger aromatic odor and taste than the preceding.

The *California spikenard* (*Aralia californica*) resembles the preceding, but the plant and the root are much larger.

3. *ARALIA SPINOSA*, *Linné*, *U. S.* 1870.—Aralia-bark, Angelica tree, Toothache bush, Prickly ash, Prickly elder, Hercules' club, *E.*; Ecorce d'aralie épineuse, *Fr.*; Dornige Aralienrinde, *G.*—This shrub or low tree is indigenous to the Southern States, and cultivated farther north. It grows to the height of 12 or, in favorable locations, 30 feet (3.5 to 9 M.); the leaves, which are crowded near the summit, are often from 4 to 6 feet (1.2 to 1.8 M.) in length, and bi- or tripinnate, with ovate pointed, serrated, and sessile leaflets, which are glaucous beneath. All parts of it are medicinal, but the bark is usually employed. It is in thin quills or curved pieces, the inner surface of which is nearly smooth and yellowish; the outer surface gray, scarcely fissured, smooth or with slight longitudinal ridges, and beset with slender prickles in transverse rows or marked with some short transverse ledges. The layer beneath the thin cork is green or brownish-green; the inner bark whitish, composed of concentric layers, and breaks with a rather tough but nearly smooth fracture. The bark has a slight aromatic odor and a bitterish, pungent, and acrid taste.

Constituents.—These drugs contain a little volatile oil, resin, starch, sugar, pectin, etc. L. H. Holden (1880) has isolated from aralia-bark the bitter principle *aralin* in the form of pale yellow scales, and J. K. Lilly (1882) obtained it in a purer state by precipitation with subacetate of lead. It is insoluble in benzine, chloroform, and ether, soluble in alcohol, and freely soluble in water, this solution forming a persistent froth on agitation. On boiling with dilute hydrochloric acid glucose is formed and white, tasteless

araliretin, which is insoluble in water. The acrid taste of the bark is due to a resin soluble in alcohol, but insoluble in ether.

4. *ARALIA EDULIS*, *Siebold*, is indigenous to Japan, and cultivated there. In appearance and size the rhizome resembles Solomon's seal, but the circular stem-scars are somewhat spirally arranged, about half an inch apart, and the wood is in radiating bundles.

5. *ARALIA PAPYRIFERA*, *Hooker*, indigenous to Formosa, contains a thick white pith, which, cut into thin layers, constitutes the so-called Chinese *rice-paper*.

Medical Action and Uses.—The name of "false sarsaparilla" applied to *Aralia nudicaulis* denotes the qualities which have been attributed to it—viz. of being stimulant, diaphoretic, and alterative. But the proofs of its virtues are unsatisfactory. It is used in decoction and infusion, both internally and externally.

Aralia spinosa is thought to be more stimulating than *A. nudicaulis*, but its uses are nearly the same. In South Carolina it was reputed to be a valuable remedy for chronic *rheumatism* and diseases of the skin, and it is said to be implicitly relied upon by the negroes as an antidote to the *rattlesnake's bite*. The bark is used for this purpose both internally and externally. A saturated tincture is said to have been given in the dose of half a fluidounce (Gm. 16) three times a day, and a decoction was used prepared with an ounce (Gm. 32) of the bark and a quart of water.

ARECA, *Br. Add.*—ARECA-NUT.

Semen Arecæ.—*Betel-nut*, E.; *Noix d'arec*, Fr.; *Arekanuss*, *Betelnuss*, G.

The seed of *Areca Catechu*, *Linné*, the betel-nut tree. Bentley and Trimen, *Med. Plants*, 276.

Nat. Ord.—*Palmae*.

Origin.—This elegant palm, which attains a height of about 50 feet (15 M.), is indigenous to the East Indies and the East Indian Islands, and is extensively cultivated there and in the Philippine Islands. The orange-colored fruit is of about the size and shape of a hen's egg, and contains under a fibrous pericarp a single seed.

Description.—The seed, which is the so-called *areca*- or *betel-nut*, is about an inch (25 Mm.) in length, roundish-conical in shape, and somewhat depressed at the base. It is of a brown color externally, with numerous reddish veins, originating at the hilum and forming a network which penetrates into the white albumen, and gives to the latter internally a marbled appearance; the small embryo is situated near the base of the seed. *Areca-nuts* are heavy, very hard, and have, when recently broken, a feeble somewhat cheese-like odor and an astringent and slightly acrid taste.

Constituents.—*Areca-nuts* contain about 14 per cent. of fixed oil, which is solid and crystalline at the ordinary temperature, and about the same amount of a red tannin which is insoluble in ether, slightly soluble in water, and resembles catechu-tannic acid in producing a green and afterward a brown color with ferric salts. Catechin is not present. The nuts yield 2.26 per cent. of ashes containing ferric oxide and magnesium phosphate (Flückiger and Hanbury). The aqueous extract of these seeds yields a kind of catechu.

Medical Uses.—*Areca* is astringent, and is chiefly used for the expulsion of *tape-worms*. From 2 to 3 drachms (Gm. 8–12), powdered and mixed with syrup, is stated to be the proper dose. Before being used to destroy these parasites in man it was largely employed for a similar purpose in dogs.

ARGEMONE.—PRICKLY POPPY.

Argémone, F.; *Stachelmohn*, G.

Argemone mexicana, *Linné*.

Nat. Ord.—*Papaveraceæ*.

Description.—This annual is indigenous to Mexico, Colorado, and the West Indies, but has been introduced and naturalized in most tropical and subtropical countries. It is about 2 feet (60 Cm.) high, has alternate sessile, sinuate-lobed leaves with prickly teeth and white spots, and yellow or white flowers, about 1½ inches (38 Mm.) in diameter, with 6 petals and many stamens. The ovate prickly capsule is about an inch (25 Mm.) thick, crowned with the nearly sessile radiate stigmas, and contains numerous blackish finely-pitted seeds. The plant has a bitter and acrid taste, and when wounded exudes a yellowish milky juice.

Constituents.—Charbonnier (1868) claims to have found a small proportion of

morphine in the leaves and capsules; like several allied plants, it probably contains sanguinarine. (See CHELIDONIUM.) The seeds yielded him 36.2 per cent. (by pressure 18 per cent., Lepine, 1861) of a drying fixed oil of a light-yellow color and bland taste. O. Frölich (1871) obtained from the oil a pretty hard soda-soap, and found in the soap-liquor butyric, valerianic, acetic, and a little benzoic acid. According to Flückiger (1871), the oil has the spec. grav. .919 at 16.5° C. (61.8° F.), remains clear at -6° C. (21.2° F.), dries slowly and incompletely, is not soluble in 6 volumes of 90 per cent. alcohol, as stated by Charbonnier, and has a mild purgative effect in doses of 4 or 5 grains.

Medical Action and Uses.—The principal quality of this plant appears to be its acrimony, in which, as well as in the physical properties of its inspissated juice, it resembles gamboge. In Mexico and in Java its fresh juice is applied to *warts* and indolent *ulcers* and in *psorophthalmia* and *opacities of the cornea*. The fresh leaves are also bruised and used as a dressing for ulcers. The juice is employed as a hydragogue cathartic in *dropsy*. Some narcotic virtue has been ascribed to the seeds, which are said to be used for smoking when mixed with tobacco. But while one authority describes them as suitable, like opium, for checking diarrhoea, another compares them to ipecacuanha, a third holds them to be purgative, and a fourth as purgative and anodyne also. The oil, derived by expression from the seeds, is reported to purge in the dose of 30 drops (Gm. 2). An infusion of the herb is stated to be used in Mexico as a sudorific.

ARGENTI CYANIDUM, U. S.—CYANIDE OF SILVER.

Argentum cyanatum.—*Cyanure d'argent*, Fr.; *Silbercyanid*, *Cyansilber*, G.
Formula $\text{AgCN} = \text{AgCy}$. Molecular weight 133.7.

Preparation.—Take of Nitrate of Silver, Ferrocyanide of Potassium, each 2 troy-ounces; Sulphuric Acid 1½ troyounces; Distilled Water a sufficient quantity. Dissolve the nitrate of silver in a pint of distilled water and pour the solution into a tubulated glass receiver. Dissolve the ferrocyanide of potassium in 10 fluidounces of distilled water, and pour the solution into a tubulated retort previously adapted to the receiver. Having mixed the sulphuric acid with 4 fluidounces of distilled water, add the mixture to the solution in the retort, and distil by means of a sand-bath, with a moderate heat, until 6 fluidounces have passed over or until the distillate no longer produces a precipitate in the receiver. Lastly, wash the precipitate with distilled water and dry it.—*U. S.* 1870.

On distilling ferrocyanide of potassium with sulphuric acid, hydrocyanic acid passes over (see ACIDUM HYDROCYANICUM), which reacts with the nitrate of silver, forming nitric acid, and cyanide of silver, which precipitates; $\text{HCy} + \text{AgNO}_3$ yields $\text{HNO}_3 + \text{AgCy}$. To avoid loss of silver the distillation should be continued as long as a precipitate is produced in the solution.

Properties.—Cyanide of silver, when dry, forms a white amorphous, inodorous, and tasteless powder, which gradually turns brown on exposure to the light, and is best preserved in amber-colored or black vials. When heated it fuses, giving off one-half of its cyanogen, and suffering further decomposition by a higher heat, leaving finally metallic silver. It is insoluble in simple solvents and in diluted acids, but is decomposed by chlorine-water, by warm solutions of chlorides and iodides, and by boiling concentrated acids, with the evolution of hydrocyanic acid, furnishing with boiling nitric acid nitrate of silver, but crystallizing from hot diluted nitric acid, partly in minute prisms. It is readily soluble in ammonia and hyposulphite of sodium, somewhat soluble in ammoniacal salts, and forms soluble double salts with the alkaline cyanides. Dilute hydrochloric acid decomposes it, yielding chloride of silver and hydrocyanic acid.

The only use of this salt in medicine is to serve for the extemporaneous preparation of diluted hydrocyanic acid.

ARGENTI IODIDUM, U. S.—IODIDE OF SILVER.

Argentum iodatum.—*Iodure d'argent*, Fr.; *Silberjodid*, *Jodsilber*, G.
Formula AgI . Molecular weight 234.3.

Preparation.—Dissolve 1 part each of nitrate of silver and potassium iodide separately in 10 or 12 parts of water; pour the silver solution gradually and with continued stirring into the solution of potassium iodide; collect the precipitate upon a filter; wash it well with distilled water and dry it upon bibulous paper. 1 ounce of silver nitrate

yields 1.34 to 1.37 ounce of silver iodide. By mutual decomposition of the two salts silver iodide and potassium nitrate are produced: $\text{AgNO}_3 + \text{KI}$ yields $\text{AgI} + \text{KNO}_3$. The former salt, being insoluble in water, is freed from the latter by washing with distilled water. The use of a slight excess of the potassium salt ensures the stability of the silver iodide in the light (H. Vogel). Should the potassium iodide be contaminated with chloride, the precipitate will likewise contain silver chloride, which, being freely soluble in ammonia, is readily removed by adding to the mother-liquor before decantation 1 or 2 parts of ammonia-water, stirring well and allowing to settle. It is advisable to keep the salt in amber-colored vials, protected from the light.

Properties.—Silver iodide is “a heavy, amorphous, light-yellowish powder, unaltered by light if pure, but generally becoming somewhat greenish-yellow, without odor and taste, and insoluble in water, alcohol, diluted acids, or in solution of carbonate of ammonium; soluble in about 2500 parts of stronger water of ammonia. When heated to about 400°C . (752°F .) it melts to a dark-red liquid, which on cooling congeals to a soft, yellow, slightly translucent mass. When mixed with water of ammonia it turns white, but regains its yellowish color by washing with water. It is dissolved by an aqueous solution of cyanide of potassium, and the resulting solution yields a black precipitate with hydrosulphuric acid or sulphide of ammonium. If a small quantity of chlorine-water be agitated with an excess of the salt, the filtrate acquires a dark-blue color on the addition of gelatinized starch.”—*U. S.* The color of melting silver iodide varies according to the temperature between yellow, red, and dark red-brown. At a white heat the salt may be sublimed, but when heated before the blowpipe upon charcoal it burns with a green flame and white smoke, leaving a little silver behind. Warm potassa solution imparts a brownish color to the salt and decomposes it on continued boiling. A concentrated solution of potassium iodide dissolves the salt, which is reprecipitated on dilution with water.

Tests.—“If the salt be boiled with test solution of carbonate of ammonium previously diluted with an equal volume of water, the resulting filtrate, on being supersaturated with nitric acid, should not be rendered more than faintly opalescent (absence of chloride).”—*U. S.* The Pharmacopœia omits to give a special test for silver bromide, which salt, however, on exposure to light speedily acquires a dark-purple color.

Action and Uses.—This appears to be superfluous addition to the Pharmacopœia. Long since obsolete, it was at one time vaunted in the treatment of *syphilis*, of *visceral neuralgia*, *asthma*, *chorea* (Guilbert, *Nouveaux médicaments*, p. 427), and even of *whooping cough* (*Practitioner*, iv. 373). The dose prescribed varied from $\frac{1}{4}$ grain to 2 grains.

ARGENTI NITRAS, *U. S.*, *Br.*—NITRATE OF SILVER.

Argentum nitricum crystallisatum, *Azotas (Nitras) argenticus*.—*Nitrate (Azotate) d'argent*, *Nitre lunaire*, *Fr.*; *Silbernütrat*, *Salpetersaures Silberoxyd*, *Silbersalpeter*, *G.*

Formula AgNO_3 . Molecular weight 169.7.

Preparation.—Take of Purified Silver 3 ounces: Nitric Acid $2\frac{1}{2}$ fluidounces: Distilled Water 5 ounces. Add the nitric acid and the water to the silver in a flask, and apply a gentle heat till the metal is dissolved. Decant the clear liquor from any black powder which may be present into a porcelain dish, evaporate and set aside to crystallize: pour off the liquor and again evaporate and crystallize. Let the crystals drain in a glass funnel, and dry them by exposure to the air, carefully avoiding the contact of all organic substances. Nitrate of silver must be preserved in bottles carefully stoppered.—*Br.*

When silver is dissolved in nitric acid, nitrate of silver is formed and hydrogen set free; the latter reacts with another portion of nitric acid, forming water and nitric oxide, which is a colorless gas, but on contact with the atmosphere is oxidized, so as to form red vapors of hyponitric acid. These reactions are explained by the following equations: $6\text{HNO}_3 + 3\text{Ag}_2$ yields $6\text{AgNO}_3 + 3\text{H}_2$; $3\text{H}_2 + 2\text{HNO}_3$ yields $4\text{H}_2\text{O} + 2\text{NO}$; $2\text{NO} + \text{O}_2$ yields 2NO_2 . The final results of the process under the circumstances stated are, therefore, water, nitrate of silver, which remains in solution, and hyponitric acid, which escapes. If insufficient heat is applied during the reaction the nitric oxide generated remains wholly or in part in solution, reducing the excess of nitric acid to nitrous and hyponitric acids. Should the solution be made in a porcelain capsule, it will be found of advantage to invert a glass funnel over the mixture, whereby not only some nitric acid, which would otherwise escape, is condensed and flows back into the dish, but the loss of silver solution by sputtering is likewise prevented. Since the best refined silver usually contains minute quantities of other metals, particularly copper, their

removal becomes necessary, and is effected either by crystallization, when the impurities, together with some silver, will remain in the mother-liquor, or the solution is evaporated to dryness and the crystalline or granular mass further heated until it is fused and ceases to give off acid vapors. The nitrate of copper and other metals are decomposed by heat before the silver nitrate is affected, and the fused mass acquires a more or less dark-gray color in proportion to the amount of cupric oxide contained in it. The latter, being insoluble in water, is easily removed by dissolving the cooled salt in distilled water and decanting or filtering the solution before evaporating it. The purification of the silver nitrate by fusion was the process recommended by the U. S. P. 1870. In following it, unless the heat be very carefully regulated, some nitrate of silver will be reduced to nitrite, and contact with organic matter will tend to deoxidize it. It is therefore advisable to acidulate the solution with a little nitric acid.

Both processes are applicable in cases where the metallic impurities are small in quantity. If silver coin is used, the first crystallization will not be pure, and if evaporated to dryness and fused a portion of oxide of silver will be separated. In such a case it is advisable either to treat the first crop of crystals by fusion or to purify the silver by one of the processes given elsewhere. (See ARGENTUM.)

Properties.—Nitrate of silver exists in colorless shining tabular crystals of the rhombic system, which are inodorous and have a caustic and strongly metallic taste and a neutral reaction. Kremers (1854) ascertained that 1 part of silver nitrate dissolves at 0° C. (32° F.) in 0.82 parts, at 11° C. (51.8° F.) in 7.83 parts (Schnauss), at 19.5° C. (67° F.) in 0.44 parts, at 54° C. (129.2° F.) in 0.20 parts, and at 110° C. (230° F.) in 0.09 parts of water. Eder found the salt soluble at 15° C. (59° F.) in 26 parts, at 50° C. (122° F.) in 13.7 parts, and at 75° C. (167° F.) in 5.5 parts of alcohol (sp. gr. .817). It is likewise, though less freely, soluble in ordinary ether, but nearly insoluble in absolute ether, freely soluble in diluted but sparingly soluble in strong nitric acid. It melts at 198° C. (388.4° F.), and on cooling congeals to a white crystalline mass; at a higher temperature nitrous vapors are given off, leaving oxide and nitrite of silver; heated to a dull-red heat, metallic silver is left. The crystals and the aqueous solution are permanent in the air and light, except in the presence of organic matter, whereby they acquire a dark color. The alcoholic solution when exposed to the light is gradually reduced, silver being separated. Hydrochloric acid produces in the solution a white curdy precipitate of argentic chloride, which is insoluble in dilute nitric acid, but dissolves readily in ammonia. Stains produced by nitrate of silver upon the skin are removed by rubbing them with a strong solution of cyanide of potassium, or by moistening them first with a solution of iodine and afterward with hyposulphite of sodium. The solution of silver nitrate acidulated with nitric acid and heated with alcohol produces the violently explosive compound known as *fulminating silver*.

Nitrate of silver contains no water of crystallization.

Tests.—1 Gm. of nitrate of silver, when completely precipitated by hydrochloric acid, should yield 0.84 Gm. dry chloride of silver. *U. S.*; 10 grains of the nitrate yield 8.44 grains of chloride. *Br.* The salt should yield with ammonia a clear and colorless solution (absence of copper, lead, etc.), and its aqueous solution, when precipitated by an excess of hydrochloric acid, should yield a filtrate which is not colored by hydrosulphuric acid, and when evaporated leaves no residue (absence of other salts). The aqueous solution, mixed with four times its volume of diluted sulphuric acid and heated to boiling, should not be turbid. *P. G.* This test indicates the absence of lead, the sulphate of which is insoluble, while silver sulphate is soluble in 68.6 parts of boiling water.

Pharmaceutical Uses.—Nitrate of silver is used in the preparation of the other medicinal compounds of silver and of indelible ink.

INDELIBLE INK is frequently made of nitrate of silver. From the numerous formulas recommended we select the following: Dissolve 2 drachms of nitrate of silver in 7 fluidrachms of distilled water, and add 1 fluidrachm of mucilage of gum-arabic, colored with sap-green or other coloring matter. This ink is used after a mordant, which is a solution of carbonate of sodium and gum in water, of the strength of 1 part of the former to from 5 to 10 of the latter (Cooley).

1 part of silver is dissolved in 6 parts each of distilled water and mucilage of gum. It is to be used with a mordant composed of 1 part of hypophosphite of sodium, 2 of gum-arabic, and 16 of distilled water (Kuhr).

The following indelible inks are used without mordant:

8 parts of nitrate of silver and 3 parts of tartaric acid are triturated together; a little water is then added, and afterward a sufficient amount of ammonia-water to neutralize

the free acid and dissolve the tartrate of silver; lastly, a little gum and coloring matter is added (Reade).

Nitrate of silver and bitartrate of potassium, of each 8 drachms, are rubbed together and dissolved in 4 ounces of ammonia-water; 4 drachms of archil, 6 of white sugar, and 10 of powdered gum are added, and when solution has taken place sufficient water to make the whole measure 6 fluidounces (Redwood).

ARGENTI NITRAS DILUTUS, U. S.—DILUTED NITRATE OF SILVER.

Argentum nitricum cum kalio-nitrico, P. G.; *Argentum nitricum fusum mitigatum*, *Lapis infernalis nitrat*us.—*Azotate d'argent diluée*, *Pierre infernale diluée*, Fr.; *Salpeterhaltiger Höllestein*, G.

Preparation.—Nitrate of Silver 50 parts; Nitrate of Potassium 50 parts; to make 100 parts. Melt the salts together in a porcelain crucible at as low a temperature as possible, stirring the melted mass well until it flows smoothly. Then cast it in suitable moulds. Keep the product in dark amber-colored vials, protected from light.—*U. S.*

Silver nitrate 1 part, potassium nitrate, 2 parts.—*P. G.*

Properties.—“A white, hard solid, generally in form of pencils or cones of a finely granular fracture, becoming gray or grayish-black on exposure to light in presence of organic matter: odorless, having a caustic metallic taste and a neutral reaction. Each of its constituents retains the solubility in water and in alcohol mentioned respectively under ARGENTI NITRAS and POTASSII NITRAS.”—*U. S.* The pencils are less fragile and more opaque than those made of pure silver nitrate. They will contain silver nitrite, and blacken on exposure to light if the salts had been melted at too high a heat. If made with sodium nitrate they become superficially moist in a damp atmosphere.

Tests.—“An aqueous solution of 2 Gm. of the compound, acidulated with nitric acid, when completely precipitated by hydrochloric acid should yield not less than 0.84 Gm. of dry chloride of silver. The filtrate, separated from the precipitate, when evaporated to dryness leaves a residue which is completely soluble in water, and which yields a white, crystalline precipitate with a concentrated solution of bitartrate of sodium.”—*U. S.* The filtrate from the silver chloride should not be affected by hydrosulphuric acid or solution of sodium carbonate. The Pharmacopœia permitting the presence of a trace of chloride in potassium nitrate, a minute quantity of silver chloride may remain on dissolving the diluted silver nitrate in distilled water.

Action and Uses.—This is merely a mitigated form of moulded nitrate of silver, and may sometimes be found convenient when a slight caustic action is intended.

ARGENTI NITRAS FUSUS, U. S.—MOULDED NITRATE OF SILVER.

Argentum nitricum (fusum), P. G.; *Lapis infernalis*, *Azotas (Nitras) argenteus fusus*.—*Fused nitrate of silver*, *Lunar caustic*, E.; *Nitrate (Azotate) d'argent fondu*, *Pierre infernale*, Fr.; *Höllestein*, *Geschmolzenes salpetersaures Silberoxyd*, G.

Preparation.—Nitrate of Silver 100 parts; Hydrochloric Acid 4 parts. Melt the nitrate of silver in a porcelain capsule at as low a temperature as possible; then add to it gradually the hydrochloric acid: stir well, and when nitrous vapors cease to be evolved cast the melted mass in suitable moulds. Keep the product in dark amber-colored vials, protected from light.—*U. S.*

To obtain the nitrate in rods, fuse the crystals in a capsule of thin porcelain or platinum, and pour the melted salt into proper moulds.—*Br.*

The reasons for the cautious application of heat when fusing nitrate of silver have been pointed out above. (See ARGENTI NITRAS.) The salt being decomposed by nearly all the metals when heated with them, capsules of platinum or of the best porcelain are the only vessels suitable for this operation. When fused it has the appearance of a colorless, transparent, oily liquid, and is then ready to be poured into the moulds, which should be faced with pure silver. Brass moulds are sometimes used, but they are liable to contaminate the product with copper. Steel or porcelain moulds may be used after they have been rubbed with some powdered French chalk, which prevents the fused salt from adhering to the mould. If the moulds have been previously warmed to about 40° or 50° C. (104° or 122° F.), the fused mass will not congeal too rapidly. Oiling the moulds should be avoided, lest a reduction of the salt should take place.

Properties.—Moulded pure silver nitrate is met with in nearly colorless thin cylinders or pointed cones, which when broken show a crystalline texture upon the fractured

surface: in solubility, chemical behavior, and composition it agrees with the crystallized nitrate. It is not affected by light unless it has been partly reduced by too high a heat to nitrate of silver or been in contact with organic matter; wrapping the sticks in paper or handling them with the fingers should therefore be avoided. The pencils are rather brittle, but the addition of a little silver chloride, as proposed by Dr. Squibb (1858), renders the sticks more opaque and tough. This is now recognized by the U. S. P., and contains about 5 per cent. of silver chloride, which is left undissolved on treatment with water; it is likewise insoluble in dilute nitric acid, but is completely soluble in ammonia-water.

Tests.—A filtered aqueous solution of 2 Gm. of the salt, acidulated with nitric acid, when completely precipitated by hydrochloric acid should yield 1.6 Gm. of dry chloride of silver.—*U. S.* This test allows a little over 5 per cent. of AgCl. For the pure lunar caustic the same tests may be applied as for the crystals. Oxide or metallic silver in very fine division is occasionally present, either in consequence of too high a heat having been employed or because the sticks have been in contact with organic matter: it will be left behind as a black powder on treating the sticks with distilled water. A convenient and readily-applied test for the purpose of detecting the presence of alkaline salts is the following: A small portion of fused nitrate of silver, rubbed into fine powder with twice its weight of sugar, forms a mixture which when burned upon a surface of glass or porcelain leaves a tasteless residue.—*U. S.* 1870. The salts of alkalies, if present, will impart a saline or alkaline taste.

Physiological Action.—*On Animals:* Experiments upon animals show that when a solution of nitrate of silver is injected into a vein the symptoms produced are dyspnoea, choking, spasms of the limbs and then of the trunk, signs of vertigo consisting of inability to stand erect or walk steadily, and finally retching and vomiting, and death by asphyxia. These symptoms, which have usually been attributed to the coagulating action of the salt upon the blood, have been shown not to depend upon that change, which indeed does not occur, but upon a direct paralyzing operation upon the cerebro-spinal centres and upon the heart; but the latter action is subordinate and secondary, and the former is fatal through asphyxia. Experiments with hyposulphite of silver injected into the cellular tissue have furnished substantially the same results, but with a predominance of nervous phenomena, including debility, torpor, somnolence, impaired muscular co-ordination, convulsion, spasm, and paralysis, during or subsequent to which, and as a consequence of the muscular disorder, respiration becomes labored and the lungs are at last engorged. The heart continues to act after the other muscles have become paralyzed. These effects, however, and some resembling them, are met with in animals that have taken silver salts internally; but there is not the slightest analogy between them and the action of those salts on man, even when they have been used long enough to thoroughly impregnate the system. The toxic action of nitrate and albuminate of silver, given internally or hypodermically to animals, is described in the results obtained by Bogoslowsky. The fundamental effect is upon the blood, which grows darker and more liquid; the red corpuscles lose their hæmoglobin and become transparent and pale, while their lost coloring matter goes to augment that of the bile. The feces increase and grow darker, while the urine is diminished in quantity, its specific gravity is raised, and it contains albumen. The mucous membranes are affected with catarrh, the muscles waste, and the blood stagnates in the vessels or transudes through the serous membranes. The liver, kidneys, heart, and fatty deposits undergo more or less atrophy. All of these effects are ascribed to a derangement of nutrition, which is equivalent to fatty degeneration—a lesion like that produced by phosphorus, arsenic, and antimony, and which reduces the organic power of the whole system. The experiments of Rózsahégzi appear to show that animals under the use of this salt steadily lose weight—that the tracheal and bronchial mucous membranes become darkly hyperæmic, while the lung-tissue is congested and may contain hepatized nodules. The epithelium of the air-passages is degenerated and the vesicles are distended with cells. The liver is at first congested and enlarged, but subsequently undergoes fatty degeneration and resorption of its cells, as well as consecutive hypertrophy of its connective tissue. In the kidneys the changes are very similar, and their tubules are distended with epithelial debris. The muscular tissue, including that of the heart, loses its color and firmness, and suffers more or less fatty change: the animal temperature is lowered by full doses of the salt; the increased waste of tissue is not indicated by the fecal discharges, nor do they contain more than a very minute proportion of the salt, which is excreted chiefly with the urine. The conclusion drawn from these results of experiment is, that the action of nitrate of silver consists essentially in causing a degradation, dissolution, and waste of the

tissues, and mainly by modifying the constitution of the blood-corpuscles, as above mentioned. It would be very difficult to harmonize the various actions attributed to nitrate of silver—its primary operation upon the blood on the one hand, and its primary action upon the nervous system upon the other; nor does either theory explain very satisfactorily the virtues attributed to the medicine in the one or two nervous diseases for which alone its systemic operation is claimed to be beneficial.

On Man: Applied to a mucous membrane or to the raw skin, nitrate of silver causes a severe smarting and burning pain, and forms a white pellicle by coagulating the albumen and fibrin of the part, which speedily dries. Upon the sound skin its prolonged application occasions vesication with a surrounding red border, but it does not cause ulceration of the chorion, and the superficial loss of substance is rapidly restored. The cauterized surface, by exposure to the light, gradually turns brown, and even black. The case is recorded of a man who for the space of a year was accustomed to dye his hair and beard with a solution of nitrate of silver. He suffered from general depression, giddiness, mental debility, hardness of hearing and tinnitus, spasm of the muscles of the eyes and face; all of which symptoms speedily disappeared on ceasing to use the hair-dye. Taken internally, by far the larger portion of the salt is discharged as a chloride of silver with the feces, but that a portion also is retained is certain, partly from its therapeutical effects, but more evidently from the peculiar violet discoloration of the exposed portions of the skin produced by its prolonged use, as well as from its detection in the kidneys, choroid plexuses, etc. An analogous stain is sometimes observed on the gums and inner surface of the cheeks before the skin is affected. As long ago as 1814, Roget reported the case (*Med.-Chir. Trans.*, vii, 290) of a lady who, after taking nitrate of silver for some time, "observed that the tongue and fauces had acquired a dark color as if stained with ink," and that subsequently the complexion grew dark. In some instances the internal organs have been found discolored as well as the skin. In the tissues the deposit is stated to exist as an oxide or as metallic silver. Several cases are recorded in which the characteristic stain followed repeated applications of lunar caustic to the throat, but doubtless the salt was swallowed (*Phila. Med. Times*, ix, 479). Nitric acid and also iodide of potassium taken internally are reported to lessen the intensity of the discoloration caused by the absorption of this salt. It is worthy of notice that when discoloration of the skin is produced by the prolonged use of small doses of the salt no other symptoms occur which can be attributed to its operation.

Doses of one-half a grain occasion no special symptoms, but larger quantities are apt to cause gastric heat, pain, and nausea. But much depends upon whether the stomach contains food or not. In poisonous doses it occasions gastric irritation and diarrhœa as its direct effect, and indirectly loss of consciousness, anæsthesia, convulsions, muscular exhaustion, a faint pulse, and a cold, clammy skin. In some cases of chronic poisoning by it a scorbutic condition is alleged to have been observed resembling that produced by this salt in animals, as already narrated. Nitrate of silver by its long-continued use has ulcerated the stomach, and a portion of fused nitrate has been arrested in the fauces and caused swelling of the glottis, in both instances destroying life.

Medical Uses.—*Internally:* In various disorders of the stomach, including morbid sensibility of that organ from chronic inflammation, neuralgia, and chronic ulcer, the use of nitrate of silver has sometimes relieved pain, checked vomiting and acid eructations, and restored health by promoting healthy digestion. The difficult diagnosis of such cases renders the application of the remedy uncertain, but its benefits are sometimes striking. *Diarrhœa*, whether dependent upon debility of the intestine or upon ulceration due to tuberculosis, or chronic dysentery, or prolonged typhoid fever, is favorably modified by nitrate of silver. In *dysentery* which is either subacute or has not entirely passed into the chronic stage enemata containing the salt are to be preferred. For these purposes about a quarter of a grain may be given by the mouth in pill, and a grain by the rectum in solution. Even in Asiatic cholera the medicine may be advantageously exhibited both by mouth and rectum. There is some evidence of its utility in chronic jaundice from an accumulation of thick bile in the ducts. Its sedative action upon the heart, demonstrated by experiments upon animals, receives a confirmation from experience, which shows it to be a palliative of abnormal action of the heart in organic as well as functional disease of that organ. In like manner, its action upon the lungs is illustrated by its beneficial effects in some cases of bronchitis with muco-purulent expectoration and hectic fever. But its efficacy in nervous diseases is still more evident in the apparent cures of epilepsy attributed to its use. The special forms of the disease which it most favorably influences are undetermined. It must be given for a long time, commencing with doses of one-quarter

of a grain three times a day, and gradually increased. Every 3 or 4 weeks its administration should be suspended for a few days in order to diminish the risk of staining the skin. Since the introduction of the bromides this medicine has, like many other anti-epileptic remedies, been almost entirely neglected. In that form of paralysis known as *locomotor ataxia* (sclerosis disseminated or limited to the lateral columns) nitrate of silver is reported to have effected cures; but a close scrutiny of the matter shows that the cases cured were not examples of this disease, but of *congestion of the cord*, generally associated with rheumatism, but sometimes resulting from concussion (ex. gr., *St. Bart.'s Hosp. Rep.*, xv. 176). In not a few instances this salt, in doses of from one-tenth to one-fifth of a grain several times a day, has effected cures when other methods failed. Relief of *dysmenorrhœa* has been attributed to the internal use of this medicine in doses of one-eighth of a grain three times a day (*Blackwood, Phila. Med. Times*, xii. 518).

Locally: Lunar caustic has been extensively employed in the treatment of *diphtheritic excoriations* of all kinds in *diphtheria*, *croup*, etc., and there is no doubt that it sometimes appears to modify favorably the affected surfaces and to prevent the increase and extension of false membranes. In the case of laryngeal croup it was at one time the custom to introduce into the larynx a strong solution of the salt (40 grains to the ounce of water) by means of a sponge or brush, but more recently an atomized solution of the same strength has been substituted. In pharyngeal diphtheria, in which the existence and condition of the false membrane are more demonstrable, as well as the influence of treatment upon it, the tendency of opinion among the most judicious physicians is less favorable than formerly to any form of local cauterization. It is alleged—and our own observation leads us to believe—that this method, which was at one time regarded as essential, is often injurious by the irritation it causes and the extension of the deposit which follows its use. In laryngeal *croup* the results of the treatment appear to be more favorable, but it must not be forgotten that the diagnosis of the disease from simple laryngitis is often obscure, and also that the immediate dependence of life upon the freedom of the larynx and trachea from obstruction must modify the conclusions arrived at in regard to the laryngeal as compared with the pharyngeal affection. The advantages of nitrate of silver in *chronic ulceration* and *simple inflammation* of the larynx and trachea are unequivocal. It exerts here the same stimulant and protective influence that it does over similar lesions elsewhere, and thus promotes the restoration of the parts to health as far as possible. As ulcers of the larynx are never primary, but always dependent upon a diathetic influence (tubercle, syphilis, cancer), a cure of them by local treatment alone is not to be expected; but this method is invaluable for the relief it affords to suffering by palliating the symptoms which the local lesions occasion. In *simple chronic laryngitis* the same treatment may suffice for a permanent cure. Many cases of *aphonia* depending upon this affection may thus be permanently cured. The stimulant action of solutions of nitrate of silver, applied by sponge, brush, syringe, or atomizer, is most efficient in the various forms of simple laryngitis, and also in nervous aphonia and in *whooping cough*. In the last-mentioned affection the pharynx as well as the larynx should be impressed by means of an atomized solution of the salt. In all the inflammations of the *pharynx*, whether acute or chronic, solutions of nitrate of silver have been used, diluted in the more acute and superficial forms and strong in the chronic follicular and ulcerous affections of the part. They are signally useful in that form known as *clergyman's sore throat*, and are the best palliatives of *tubercular* and *syphilitic* ulcers of this part. A comparatively weak atomized solution is more efficient in these cases than a strong solution applied with a sponge or brush.

If in any case it is possible to prevent *tonsillitis* from passing into *quinsy*, this end may be most securely reached by the application of lunar caustic freely to the swollen gland. But the termination in suppuration can never, in a particular case, be predicted with certainty. It sometimes happens also that this use of the caustic appears to promote and not to hinder suppuration. Local vesication by means of a saturated solution of the crystallized salt or with the fused nitrate is an efficient means of treating various local ailments. It may be used over the superficial portions of nerves in various *neuralgias*; superficially also over *lymphatic vessels* and *glands* in the first stage of inflammation; *paronychia* and other forms of local inflammation, such as *abscesses*, may be treated in the same way. It has been used to blister the brow in *iritis*. It has been also applied by deep injection in *sciatica*. The value of this treatment may be measured by the fact that a precisely similar result ensued upon the injection of pure water. The silver salt so injected causes severe pain, followed by abscess. The substitutive action of nitrate of silver is pre-eminently useful in *ophthalmia* or *conjunctivitis*. In different degrees of

strength it may arrest the development of a mild inflammation or so modify the membrane as to cure the most chronic forms of this affection. The disused practice of producing counter-irritation in these affections by blistering the brow with this caustic has been recommended anew (*Med. Times and Gaz.*, Dec. 1879, p. 635). In treating ulcers of the *cornea* care should be taken lest the undissolved or precipitated salt should permanently stain the structure and form an obstacle to distinct vision. *Blepharitis*, or inflammation of the follicles of the edges of the lids, is said to be well treated with an ointment of nitrate of silver (gr. iij to ʒj), but it is better to touch the parts with a strong solution of the salt and then cover them with simple ointment. Of all agents for modifying ulcers, none is so frequently applied as nitrate of silver. Its internal use for this purpose has already been noticed, but it is still more commonly applied to ulcers of the external integument—to the irritable in weak solution as an astringent, stimulant, and protective, and to the indolent in caustic form to destroy inert tissue, or rather to revive its dormant vitality. Probably no other single agent is so useful in the treatment of ulcers, or none whose effects can be so readily modified by the degree of action allowed in its application. Thiersch has used a solution of 1 part of the salt to 1000 of water to make subcutaneous injections around and beneath indurated ulcers, with the effect of curing some which resisted all other methods. The operation is painful and should be performed during anaesthesia (*Boston Med. and Surg. Jour.*, May, 1881, p. 500). Fused nitrate of silver, in the form of a fine point, is an efficient means of arresting hæmorrhage from *leech-bites*. This caustic has been used with advantage in treating punctured and lacerated wounds, and especially poisoned wounds. In the former case it produces a protective film, and in the latter probably tends to destroy the virus. It is one of the best remedies for *mercurial sore mouth* in its ulcerative stage. Its stimulant and protective actions combined make it a useful application to ulcers of the skin, and especially to those of an indolent character; and these, as well as its action upon the specific virus of *chancres*, render it a valuable agent in their first stage. It is generally held that if induration have already taken place this treatment will not prevent constitutional infection, but some maintain that it is useless, no matter how early it is employed. A similar ectrotic method has been used to prevent pitting in *small-pox*, and often with apparent success. The application of a strong solution of the salt during the papular, or early in the vesicular, stage sometimes arrests the development of the pox. The same method has been used in *zona*, *herpes*, and *intertrigo*, but in the last-named affection the solution should be weak (gr. v to fʒj). In the treatment of *sore nipples* the caustic pencil may be applied to the fissures or ulcers or the part may be enveloped with lint wet with a weak solution of the salt. A case is recorded in which a *vascular nevus* of the hand was injected with a few drops of a concentrated solution of the salt. Intense pain immediately followed and coldness of the limb, and two fingers became black and dry up to the second joint, and subsequently were amputated (*Phila. Med. Times*, xi. 795).

Burns, if superficial, may be treated with the fused preparation, or merely brushed over with a strong solution of the nitrate and then closely enveloped in lint or carded cotton. The same method has been much employed in *erysipelas* when it affects the face alone, and also when it involves the scalp. A strong solution is to be preferred, and the earlier in the attack it is used the more apt are its effects to be beneficial. It must, however, be remembered that erysipelas of the face is not usually a local inflammation merely. Nitrate of silver is of great value in treating several diseases with purulent discharges, as *otorrhœa*, *gonorrhœa*, and *leucorrhœa*. In the second of these affections it should be cautiously used, at least in the male, during the acute stage; too strong a solution has been known to cause violent inflammation of the urethra and bladder, orchitis, etc. The former custom of treating inflammation of the neck of the bladder by means of Lallemand's *porte-caustique* has been imitated by injecting a solution (1 part to 50) from a hypodermic syringe with a very long nozzle enclosed in a fenestrated bougie with an olive-shaped extremity (*Bulletin de thérap.*, xcvii. 580). It is the best application in gonorrhœa of the glans penis, or *balanitis*; if the prepuce cannot be withdrawn a solution of the salt may be injected. It should be of the strength of gr. xx—xxx to fʒj, and a similar one may be used for gonorrhœa in the female and for leucorrhœa. If the latter affection has its source in the neck or body of the uterus, the solution or the solid caustic may be introduced into that organ. But this is an operation attended with serious risks unless performed with the utmost caution. It has been successfully employed to cure *amenorrhœa* from uterine torpor, a solution of 1 or 2 grains to the ounce being injected into the cavity of the uterus. Braun of Vienna, who is opposed to the production of abortion to relieve the *vomiting of pregnancy*, states that he has arrested this symptom completely by applying

to the vaginal portion of the neck of the uterus a 10 per cent. solution of nitrate of silver (*Practitioner*, xxviii. 447).

A solution of 1 or 2 grains to the ounce injected into the bladder is efficient in the treatment of *vesical catarrh*. *Ascariæ* of the rectum are said to be destroyed by injections of nitrate of silver containing about 3 grains of the salt to an ounce of water. *Strictures of the urethra* are habitually treated with the solid nitrate applied by means of the caustic-holder of Lallemand. This method is most applicable to linear and spasmodic strictures. The same treatment, applied to the prostatic portion of the urethra, has been much in vogue as a remedy for *involuntary seminal emissions*, and is often efficient where these discharges depend upon debility, and therefore morbid excitability, of the sexual organs, induced by prolonged self-abuse. Nitrate of silver may assist in removing *corns* after the hardened and thickened cuticle has been removed by prolonged maceration in warm water or by a poultice. As often as the blackened lamina exfoliates the operation should be repeated.

Administration.—By the mouth, nitrate of silver is nearly always given in a pill, which should be made with some bitter vegetable extract, but not with bread-crumbs, which contains salt. But even such precautions do not long prevent its decomposition. It should be administered when the pills are freshly made and the stomach is empty, in order to delay this result. Such, at least, is the usual direction, but it is pretty certain that under no circumstances is the nitrate of silver absorbed unchanged. The dose is from $\frac{1}{4}$ grain to 1 grain (Gm. 0.01–0.06) three times a day. A convenient mode of preserving fused nitrate of silver is to dip the stick into melted sealing-wax, which gives it a coating that protects it from the air and prevents its staining the fingers. A tougher preparation than the fused nitrate is prepared by mixing with the latter a portion of oxide of silver. 5 parts of nitrate of silver melted with 1 part of nitrate of lead form another compound, of which cylinders are made not liable to fracture and that can be cut like a lead-pencil. The stick of lunar caustic may be pointed by rotating it upon a hot silver coin. The stain of nitrate of silver upon the skin, clothing, etc. may be removed by a solution of cyanide, and somewhat less perfectly by a solution of iodide of potassium; or the stain may be moistened with tincture of iodine, and then with ammonia, and the colorless residue removed with water. A solution of 1 part each of ammonium chloride and corrosive sublimate in 10 parts of distilled water will remove the stains from the skin, and from woven stuffs without injuring the fabric. It must be kept in glass-stoppered bottles (Kætzner). Flaxseed mucilage is also recommended for the same purpose. The proper *antidote* to nitrate of silver in the stomach is a large draught of a weak solution of table-salt, so as to decompose the nitrate and induce vomiting. The resulting irritation may be allayed by milk, which should also serve for food until the stomach is restored. The excessive action of the nitrate upon the fauces, vagina, skin, etc. may also be checked by salt and water.

ARGENTI OXIDUM, U. S., Br.—OXIDE OF SILVER.

Oxidum argenticum, *Argentum oxydatum*.—*Argentio oxide*, E.; *Oxyde d'argent*, Fr.; *Silberoxyd*, G.

Formula Ag_2O . Molecular weight 231.4.

Preparation.—Take of Nitrate of Silver in crystals $\frac{1}{2}$ ounce; Solution of Lime 70 fluidounces; Distilled Water 10 fluidounces. Dissolve the nitrate of silver in 4 ounces of the distilled water, and, having poured the solution into a bottle containing the solution of lime, shake the mixture well and set it aside to allow the deposit to settle. Draw off the supernatant liquid, collect the deposit on a filter, wash it with the remainder of the distilled water, and dry it at a heat not exceeding 100°C . (212°F). Keep it in a stoppered bottle.—*Br*.

A similar process, but using a sufficient amount of solution of potassa in place of the lime-water, was recognized by the U. S. P. 1870. In both cases the nitrate of silver is decomposed, yielding oxide of silver, water, and nitrate of potassium or calcium: $2\text{AgNO}_3 + 2\text{HKO}$ yields $\text{Ag}_2\text{O} + \text{H}_2\text{O} + 2\text{KNO}_3$, and $2\text{AgNO}_3 + \text{Ca}_2\text{HO}$ yields $\text{Ag}_2\text{O} + \text{H}_2\text{O} + \text{Ca}_2\text{NO}_3$. It is important that these alkaline solutions, in place of which solution of soda may be used, should be free from chlorides, which would precipitate a portion of the metal as chloride of silver, and the presence of carbonate in the potassa or soda solution would cause the oxide to be contaminated with carbonate of silver. Oxide of silver may be likewise obtained, according to Gregory, by boiling recently precipitated moist chloride of silver with an excess of potassa solution, specific gravity 1.25 to 1.3, until a portion of the sediment is completely soluble in diluted nitric acid. To prevent the chloride

from caking together. Mohr recommended the diffusion of it in some water and its gradual addition to the boiling potassa solution.

Properties.—Prepared by precipitation from the nitrate, oxide of silver is an inodorous olive-brown or blackish powder, having the spec. grav. 7.52 and a disagreeable metallic taste. Obtained by Gregory's process, it is black or bluish-black. It is slightly soluble in 3000 parts (Bineau) of water, the solution having an alkaline reaction and a metallic taste; the solution acquires a reddish tint in the light, and in the presence of carbonic acid becomes at first turbid and afterward clear again. The oxide is insoluble in alcohol and ether, forms carbonate when kept moist, and is slowly decomposed by exposure to light, and rapidly and completely by heating it to 300° C. (572° F.), into silver and oxygen; it should therefore be well dried and kept in dark amber-colored bottles, protected from light. Freshly-prepared oxide of silver is wholly, after drying and keeping only partly, soluble in ammonia-water, leaving a black powder, *Berthollet's fulminating silver*, and the solution depositing black crystals of the same compound, which is violently explosive. The oxide, moistened with creasote or when mixed with tannin, amorphous phosphorus, precipitated sulphur, the sulphides of arsenic and antimony, or with other readily oxidizable or combustible substances, renders these spontaneously inflammable.

Oxide of silver is soluble in solution of nitrate of barium, and yields with solutions of chlorides, bromides, and iodides the corresponding silver salts. It combines with acids, forming salts, many of which are colorless or white, and become dark-colored on exposure to light, some only in the presence of organic matter. Many metals, like zinc, lead, iron, copper, etc., precipitate metallic silver from the solutions of its salts, and a similar reaction takes place with phosphorus, phosphorous acid, many organic compounds, and deoxidizing agents.

The most characteristic reactions of solutions of silver salts are obtained with chromate of potassium, which produces a deep purplish-red precipitate soluble in nitric acid. Chlorides and cyanides yield white curdy precipitates insoluble in dilute nitric acid, soluble in ammonia and cyanide of potassium; bromides give a yellowish-white precipitate little soluble in ammonia; and with iodides a yellowish precipitate is obtained which is nearly insoluble in ammonia. The lemon-yellow precipitate obtained with orthophosphate of sodium is readily soluble in ammonia and nitric acid.

Tests.—Oxide of silver should be completely dissolved without effervescence in dilute nitric acid, and the solution, when precipitated by an excess of hydrochloric acid, should yield a filtrate leaving no residue on evaporation to dryness. 29 grains of the oxide, when heated to redness, leave a residue of metallic silver weighing 27 grains.—*Br.* 1 Gm. of the oxide, when treated with an excess of hydrochloric acid, should yield 1.236 Gm. of chloride of silver.—*U. S.*

Medical Action and Uses.—Oxide of silver appears to possess the virtues which belong to the nitrate, but in a much less degree. It is slightly caustic, and its prolonged internal use occasions a purplish color of the skin. It was at one time supposed to possess a peculiar power over passive *hemorrhages*, particularly from the uterus, but it is not to be compared with several salts of iron, or even with certain vegetable astringents, in this respect. Owing to its less caustic qualities it may possibly be preferable to the nitrate in *gastralgia*, simple *gastric ulcer*, and painful *dyspepsia* depending upon irritability of the mucous membrane of the stomach. In all local affections which call for a mild stimulant and astringent, such as *catarrhal affections* of the nostrils, throat, larynx, vagina, urethra, etc., a weak solution of the nitrate of silver is greatly to be preferred. *Dose*, from $\frac{1}{2}$ to 2 grains (Gm. 0.03–0.13) two or three times a day, incorporated with a vegetable extract. An ointment is used containing from 40 to 80 grains (Gm. 2.60–5.20) of the oxide to an ounce of lard.

ARGENTUM.—SILVER.

Argentum purificatum, Br.—*Refined Silver*, E.; *Argent*, *Argent raffiné*, Fr.; *Silber*, *Raffinirtes Silber*, G.

Symbol Ag. Atomicity univalent. Atomic weight 107.7.

Origin.—This metal was known and in use in the earliest historic period, and was called *Luna* or *Diana* by the alchemists. It is found pure and in combination with various metals, and with sulphur, chlorine, bromine, iodine, etc., the richest silver ores being in the Western United States, Mexico, Peru, Norway, Russia, Germany, and Spain.

Preparation.—The extraction of the metal is effected by different processes, the

details varying considerably with the richness and the composition of the ore. The process of *amalgamation* is based upon the formation of an alloy between metallic mercury and silver. The finely-powdered ore is intimately mixed with chloride of sodium and then roasted, when the mass contains, besides metallic silver, its chloride, the latter being converted to the metallic state by agitation in a revolving cylinder with water and iron. Mercury is now added and the agitation continued, when the silver, gold, and copper unite with the mercury, the amalgam being obtained by subsidence and washing, and afterward separated into a liquid and solid portion by subjecting it to pressure in strong linen or leather bags. By distilling the solid portion the mercury is evaporated off and recovered, while the silver remains behind, containing copper and gold.

In the process of *cupellation* the galena containing silver is first reduced and the metallic lead allowed to cool slowly, when almost pure lead crystallizes, and is removed by means of a ladle or by carefully draining off the liquid portion, which is rich in silver. This is exposed to a red heat, and air directed upon it by means of a blast, whereby the lead is oxidized and the litharge blown off, leaving silver containing some lead. This is now transferred to a dish made of bone-ash and heated to redness; the plumbic oxide formed is absorbed by the porous vessel, and finally almost chemically pure silver is left.

By the careful roasting of the ore containing the metals as sulphides these are converted into sulphates, which are treated with hot water; from this solution the silver is precipitated by metallic copper, the latter being subsequently recovered by precipitation with iron.

Many modifications of these and some other processes are employed, the silver obtained on the large scale always retaining a small portion of other metals.

Chemically pure silver is obtained in various ways from the chloride, which is readily prepared free from other chlorides by precipitating the solution in nitric acid with hydrochloric acid and washing it thoroughly with water. The chloride of silver is then reduced by boiling it with glucose and sodium carbonate; the powdered silver thus obtained is well washed with acetic acid and water and then fused. Or the chloride is mixed with acidulated water and a rod of zinc introduced, the silver being afterward fused with borax and saltpetre. Or a mixture of the chloride with carbonate of sodium and of potassium is heated, whereby silver, alkali chlorides, carbonic acid, and oxygen are formed; $2\text{AgCl} + \text{KNaCO}_3$ yields $\text{Ag}_2 + \text{KCl} + \text{NaCl} + \text{CO}_2 + \text{O}$.

Properties.—Silver is a brilliant white metal, very ductile and malleable, having the specific gravity 10.47 when obtained by fusion; the pressed and the distilled silver have a density of 10.57. It may be drawn into very fine wire and beaten into very thin *silver-leaf*, *Argentum foliatum*. It melts at about 1000°C . (1832°F .), absorbs oxygen, which on cooling is again given off, but it does not oxidize in contact with the air or at a red or white heat, and distils at the heat of the oxyhydrogen blast. It tarnishes superficially through the sulphuretted hydrogen contained in the atmosphere, and dissolves completely in diluted nitric acid.

Tests.—The solution of chemically pure silver in hot diluted nitric acid, when precipitated by hydrochloric acid, yields a filtrate which is not darkened by hydrosulphuric acid, and on evaporation to dryness leaves no residue.

Pharmaceutical Uses.—Metallic silver is employed for making the officinal silver compounds, and in the form of silver-leaf serves occasionally as a coating for pills.

Medical Uses.—In its metallic form silver possesses no direct medicinal virtues. Its ductility, malleability, and slight susceptibility to oxidation fit it peculiarly for a vast number of uses in surgery.

ARMORACIÆ RADIX, *Br.*—HORSE RADISH-ROOT.

Rai fort sauvage, Montarde des moines, Radis de cheval, Fr.; Meerrettig, Merrettig, G.

The fresh root of *Cochlearia Armoracia*, *Linneé*, s. *Armoracia* (*Cochlearia*, *Lamarck*) *rusticana*, *Gærtner*, s. *Arm. sativa*, *Heller*. Bentley and Trimen, *Med. Plants*, 21.

Nat. Ord.—Cruciferae, Siliculose.

Origin.—This perennial plant is indigenous to the eastern part of Europe, and cultivated in Western Europe and North America, where it has been naturalized. It has large oblong erenate or sometimes pinnatifid root-leaves on long channelled petioles, lanceolate stem-leaves, and a long racemose inflorescence; the flowers are white and the ascending pods roundish.

Description.—The root attains a length of from 1 to $2\frac{1}{2}$ feet (30 to 75 Cm.) and a thickness of $\frac{1}{2}$ to 1 inch (12 to 25 Mm.); it is cylindrical in shape and crowned with several

annulated heads. It is covered with a light yellowish-brown corky layer, and breaks with a short fracture, exhibiting the fleshy white interior. The bark is thin, contains a number of yellow thick-walled cells, and is separated by a dark-colored cambium-line from the medullium, in which the radiate arrangement of the vascular bundles and medullary rays, and frequently also the circles of annual growth, are easily discernible. A large central pith is found in the head. In its unbroken state it is nearly inodorous, but when broken or bruised it has a very pungent odor and a sharp acrid taste. It is employed in the fresh state only.

Constituents.—The volatile oil to which the odor and taste of horseradish are due has the same chemical composition as oil of mustard, $\text{CSN.C}_3\text{H}_5$, though it differs from it somewhat in odor; the crude oil, of which about $\frac{1}{10}$ per cent. of the weight of the fresh root is obtained, is of a light-yellow color; the rectified is nearly colorless, of 1.01 specific gravity, and becomes dark-colored by age. It does not pre-exist in the root, but, according to Boutron and Frémy (1840), is formed in a manner similar to that of the volatile oil of mustard. Besides the volatile oil, Gutret (1792) ascertained the presence of some bitter resin, extractive, sugar, starch, gum, albumen, acetates, and other salts, 12.5 per cent. of lignin, and 78.1 per cent. of water. Mutschler (1878) found the fresh root to lose 83.45 per cent. on drying, and then to yield 11.75 per cent. of ash, consisting mainly of potassium and calcium salts.

Off. Prep.—*Spiritus armoraciae compositus, Br.*

Medical Action.—Horseradish, in the fresh state or pickled, has a very pungent and acrid taste, irritates the fauces and the nostrils, and causes a flow of tears. It is a familiar condiment, especially for beef. It excites a sense of warmth in the stomach, stimulates the appetite, and promotes digestion. In excessive doses it occasions burning at the epigastrium, nausea, and vomiting. It augments the urine, and probably the perspiration also, and gives to the former a peculiar odor. Externally applied, it reddens and sometimes blisters the skin. These qualities depend upon its volatile oil, which has at first a sweetish and then an extremely acrid taste and a pungent and very diffusive odor.

Uses.—Horseradish has had great renown as a remedy for *scurvy*, and the resemblance of its taste to that of scurvy-grass (*Cochlearia officinalis*) is noteworthy. The disease is much less common now than when anti-scorbutics were in vogue, and when this medicine ranked high among them. In the treatment of *dropsy* it has been replaced by more potent drugs. Nevertheless, it deserves its reputation as a diuretic in all forms of cardiac, renal, hepatic, and splenic dropsy which are characterized by a feeble, atonic condition of the system. It is advantageous as a condiment in many cases of *dyspepsia* with feeble appetite, oppression after eating, and flatulence, and in gastric debility attended with *vomiting* even when excited by reflex irritation. As a local irritant it is sometimes used to relieve *toothache*, to stimulate the *fauces*, to correct relaxed states of the mucous membrane, and to remove the hoarseness produced by congestion of the *larynx*. For these purposes it may be employed as a masticatory, or a strong infusion of it may be applied as a gargle. It may be resorted to as a counter-irritant in all the cases in which mustard is appropriate, to arouse sensibility, to relieve pain, excite motility, etc. A mixture of the juice with vinegar has been used to remove *freckles* and *tan* (*ephelis*). The compound spirit of horseradish is a convenient addition to diuretic infusions and mixtures. An infusion may be made with an ounce (Gm. 32) each of freshly-grated horseradish and bruised mustard-seed in a pint of hot water, macerated for 2 hours. A wine-glassful may be taken three or four times a day.

ARNICA.—ARNICA.

Arnique, Arnica, Fr.; Wohlverleih, Fallkraut, Arnika, G.

Arnica montana, Linné. Woodville, t. 17; Bentley and Trimen. *Med. Plants*, 158.

Nat. Ord.—Compositæ, Senecionideæ.

Official Parts.—1. ARNICA FLORES, *U. S.*; Flores arnicæ, *P. G.*—Arnica-flowers, *E.*; Fleurs d'arnica, *Fr.*; Arnikablüthen, *G.* The flowers.

2. ARNICA RADIX, *U. S.*, *Br.*—Arnica-root, *E.*; Racine d'arnica, *Fr.*; Arnikawurzel, *G.*—The rhizome and rootlets.

Origin.—This species of arnica is indigenous to Europe, growing upon the mountains of Switzerland and Germany and farther north in the plains. It is likewise met with in Northern Asia and in the north-western part of America. It bears a tuft of ovate or oblong-obtuse radical leaves with a nearly entire and ciliate margin, and produces a stem

about 10 to 12 inches (25 to 30 Cm.) high, with a few lanceolate leaves and a few branches, each of which bears one flower. The flowers appear in May, and on drying lose about 80 per cent of their weight.

FIG. 31.

FIG. 32.

FIG. 30.

Arnica: transverse section of rhizome, natural size and magnified 10 diam.

Arnica montana, Linné: ray- and disk-floret.

Arnica: section through rootlet, magnified 25 diam.

Description.—1. **THE RHIZOME.** It is horizontal, somewhat contorted, 2 or 3 inches (5 to 7 Cm.) long, and $\frac{1}{8}$ or $\frac{1}{4}$ inch (3 or 4 Mm.) or less in diameter, longitudinally wrinkled, uneven, and rough from the scars of the decayed stems and leaves. Its color externally is dark-brown; the rather thick bark has about one-eighth the diameter of the rhizome, is internally whitish, and contains a circle of brown-yellow resin-cells. The yellowish wood forms broad wedge-shaped bundles and encloses a large central spongy pith. The numerous rootlets issue from the lower side of the rhizome, are 2 to 4 inches (5 to 10 Cm.) long, thin and fragile, and consist of a thick bark and a thin cylindrical cord of yellowish wood, which is surrounded by a circle of resin-cells.

Arnica-root is collected in the spring, and is occasionally found in the market with the radical leaves, which should be removed when used for medicinal purposes. It has a faintly aromatic odor and a rather persistent acrid taste.

2. **THE FLOWERS.** The heads, which are from 1 to 2 inches (25 to 50 Mm.) in diameter, are surrounded by an involucre consisting of a double row of imbricated equal and hairy scales. The flat, finely-pitted, and chaffy receptacle is about $\frac{1}{4}$ inch (6 Mm.) in diameter, and bears fifteen to twenty pistillate bright-yellow, parallel ten-veined, and three-toothed ligulate ray-florets about an inch (25 Mm.) in length, and many perfect tubular five-toothed disk-florets. The brown and hairy akenes are slender, spindle-shaped, obtusely five-angled, brown, short-hairy, about $\frac{1}{4}$ inch (6 Mm.) long, and are crowned by a pappus consisting of a single row of denticulate gray hairs about $\frac{1}{8}$ inch (8 Mm.) in length. The odor of the flowers is feebly aromatic and their taste acrid and bitter. The German Pharmacopœia directs the removal of the involucre and receptacle. The flowers, and more particularly the receptacle, are often attacked by the black larvæ of the arnica-fly, *Trypeta arnicivora*, Loew., which must be removed. The powder of arnica-flowers is irritant and sternutatory.

Constituents.—Besides gum, wax, and salts the root and flowers contain two different volatile oils. The dry root yields about $\frac{1}{2}$ to 1 per cent. of volatile oil, of nearly the density of water, and isobutyric acid, with small quantities of formic and angelic acid; old root yields more acids and less volatile oil than fresh root. The volatile oil, which boils between 214° and 263° C. (417° and 505° F.), is remarkable for containing at least three rare ethers—phloryl-isobutyrate, a phlorol-methylic ether, and, in largest proportion, the dimethylic ether of thymo-hydroquinone (Sigel, 1873). The name of *arnicin* has been applied to different principles found in the root and flowers. Pavesi's arnicin (1859), obtained by the process for preparing santalin, is a dark-yellow, sticky resin of a disagreeable bitter taste, which is not freely soluble in alcohol and ether, but readily in alkalies, from which solutions it is again precipitated by acids. Bastick's arnicine (1851) was obtained by exhausting the flowers with alcohol acidulated with sulphuric acid, treating the tincture with an excess of lime, adding to the filtrate sufficient sulphuric acid, evaporating, diluting with water, filtering, neutralizing with carbonate of potassium, again filtering, treating the liquid with excess of carbonate of potassium, and agitating with ether, on the evaporation of which arnicine is left. It is stated to have a bitter taste and alkaline reaction, and to yield with acids crystallizable salts. The arnicin of Walz

(1861) is a golden-yellow amorphous acrid mass, which is slightly soluble in water and soluble in alkaline liquids, in alcohol, and in ether. It may be prepared from the flowers, which contain it in larger proportion than the root, by passing the tincture through animal charcoal, evaporating, and treating the residue with ether, which dissolves arnicin and fat, the former of which is afterward dissolved by alcohol of 0.85 specific gravity. It is also obtained by precipitating the watery decoction with tannin, exhausting the precipitate with alcohol, and removing the tannin by oxide of lead, and the lead by sulphuretted hydrogen. By decomposition with alkalis and acids, resin, oil, and a volatile acid have been obtained.

Arnica root and flowers appear also to contain several resins, at least one of which is insoluble in ether and has an acrid taste. The root contains 10 per cent. of inulin, according to Dragendorff (1870).

Adulterations and Substitutions.—The flowers are said to be occasionally adulterated with other yellow composite flowers, but are easily distinguished by the characters given above: those of *calendula* and *anthemis* are destitute of pappus; those of *inula*, *doronicum*, and *senecio* have a naked receptacle; and those of *scorzonera* and *tragopogon* have all the florets ligulate. The rhizomes and roots of other *Compositæ* which are said to be occasionally collected by mistake for arnica-root differ from it in physical characters; there is no difficulty in distinguishing the latter from the root of *Geum urbanum*, noticed as an adulteration by E. M. Holmes (1874).

Off. Prep.—Of the flowers: *Tinctura arnicæ florum*, *U. S.* Of the root: *Extract. arnicæ radicis*, *Extr. arnicæ rad. fluid.*, *Tinct. arnicæ rad.*, *U. S.*; *Tinct. arnicæ*, *Br.*

Physiological Action.—*On Animals:* Experiments upon horses, in which an infusion of arnica was administered by the stomach or by the veins, proved this preparation to be a direct stimulant of the arterial and nervous systems of these animals, increasing the temperature and the secretion of urine; but its secondary effects consist of muscular tremors, depression, debility, and apparently anæsthesia. These effects are, however, transient.

On Man: The local action both of the root and the flowers of arnica is irritant, but that of the flowers is the more powerful. The tincture, applied for insignificant injuries, has occasioned inflammation and vesication. Fayer relates that 6 days after having applied it to his wrist for a sprain the part was slightly stung by a nettle; immediately an inflammation of the skin arose, limited accurately to the previous contact of the arnica, but causing inflammation of the lymphatics of the limb (*Practitioner*, xvi. 52). Internally, a strong infusion irritates the throat, produces a burning pain in the stomach, tends to excite vomiting, increases the frequency of the heart's action, the respiration, and the secretions of the skin, bronchia, and kidneys, and occasions headache, giddiness, inability to stand or walk, and disturbed sleep. These symptoms are followed by depression and exhaustion. After excessive doses the phenomena of stimulation are not observed, but in their stead vomiting, purging, giddiness, oppression, debility, cold extremities, frequent pulse, dilated pupils, muscular spasms, and collapse, with infrequent pulse. Death is reported to have occurred in the case of a man who drank from 2 to 2½ ounces of the tincture (*Lancet*, July 10, 1880). The nauseant properties are said to belong to the flowers rather than to the root.

Medical Uses.—The conclusions respecting the operation of arnica to be drawn from the foregoing phenomena are essentially the same as those which its use as a medicine indicates. Its vogue has always been greatest in the treatment of affections that require stimulation. Especially has it been reputed to be an efficient stimulant in all diseases presenting the *typhoid state*, in the continued fevers which most frequently assume that condition, and in the various inflammations which it may complicate. As a disease which partakes of both natures, and which often presents the typhoid type, *dysentery* may be mentioned, and arnica is said to have been efficient in its treatment. Its stimulant local action has been thought sufficiently powerful to suggest its use in liniments and tinctures applied by friction to paralyzed muscles. In Germany this action has long been popularly employed for the relief of local *paralyses*, *bruises*, *sprains*, *abrasions*, slight *wounds*, etc.; whence its name *Fallkraut*, which may be translated *accident-plant*. It is alleged that only the infusion or decoction, and not the tincture, should be used for these purposes—a statement which popular experience would seem to contradict. Frictions with the tincture need not, however, prevent the more permanent influence of fomentations made with the flowers steeped in water or vinegar. Powdered arnica-flowers are said to limit the progress of *mortification*. 1 part of an extract of fresh arnica-flowers and 2 parts of honey, thickened with an inert powder if necessary, and kept applied to

boils, is said to arrest their development at any stage (Planat, *Amer. Jour. of Med. Sci.*, Apr. 1878, p. 545). The watery preparations are, however, more suitable internally in the cases above alluded to of febrile disease, and also in those of exhaustion from shock; but their use should not prevent the more serviceable employment of alcoholic stimulants. The *dose* of the powdered root may be stated to be from 10 to 30 grains (Gm. 0.60–2.00). A decoction may be made with 120 grains (Gm. 8) of the root in 9 fluidounces of water reduced by boiling to 6 fluidounces. Of this the dose is a tablespoonful or more every 2 hours. An infusion is made of a drachm, and from that to an ounce (Gm. 4–30) of the flowers, in 6 fluidounces of water. *Dose*, a tablespoonful or more.

ARNOTTA.—ANNOTTA.

Orellana, Orleana.—Rocon, Terre de la Nouvelle-Orléans, F.; Orlean, G.

A coloring matter obtained from the seeds of *Bixa Orellana*, *Linneé*.

Nat. Ord.—Bixaceæ.

Origin and Preparation.—This medium-sized tree is indigenous to tropical America, and produces roundish, heart-shaped, or subreniform capsules, containing numerous obovate, angular, whitish seeds, which are about $\frac{1}{8}$ inch (3 Mm.) long and are covered with a dark-red pulp. The seeds are soaked or allowed to ferment in water, rubbed between the hands and upon a sieve, crushed, and finally completely mashed and again washed with water. The coloring matter subsides and is formed into cakes; the water likewise contains a coloring matter. (See paper by Th. Peckolt, in *Amer. Jour. Phar.*, 1859, p. 360.) The importation of annotta-cake and seed into this country has increased from 160,500 pounds in 1876 to 412,610 pounds in 1882.

Description.—Annotta, also called *annatto*, exists in cakes which are either plastic or hard, of a nearly blood-red color, becoming red-brown on exposure, of a peculiar odor and disagreeable saline and bitter taste. It is nearly insoluble in water, but colors it yellow, and dissolves almost completely in alcohol, ether, fixed oils, and alkalies, with an orange-red or dark-red color.

Constituents.—According to the investigations of John Kerndt (1849), Piccard (1861), Mylius (1864), and W. Stein (1867), annotta contains *orellin*, a yellow coloring matter soluble in water, and bright red *bixin*, which is not freely soluble in cold alcohol and ether, but readily dissolves in alkalies. The latter is colored blue by strong sulphuric acid, and with nitric acid produces a yellow body of a musk-like odor. Its composition is, according to Stein, $C_{15}H_{18}O_4$, according to Etti (1878), $C_{28}H_{34}O_5$. Annotta contains also a fatty acid, a turpentine-like body, and various other compounds. A. E. Ebert (1868) obtained from the air-dry seeds 5.15 per cent. of ash, the chief constituents of which are potassa, silica, and phosphoric acid.

Uses.—It is to some extent employed as a dyestuff for silk and other fabrics, and for the coloring of plasters and ointments, as well as of butter and cheese. For *butter-coloring* annotta is digested with alcohol until completely disintegrated, and then heated with four or five times its weight of olive or other bland oil; for *cheese-coloring* a little turmeric is added.

Adulterations with ochre, brickdust, sand, gypsum, and the like are discovered by their insolubility in hot alcohol.

ARSENI IODIDUM, U. S.—IODIDE OF ARSENIC.

Ioduretum arseniosum, Arsenicum (Arsenum) iodatum; Arsenici iodidum, U. S. 1870.—*Arsenious iodide*, E.; *Iodure d'arsenic*, Fr.; *Arsenikjodür*, G.

Formula AsI_3 . Molecular weight 454.7.

Preparation.—Triturate in a mortar finely-powdered metallic arsenic 75 grains and iodine 380 grains until they are thoroughly mixed. Put the mixture into a small flask or test-tube loosely stoppered, and heat it very gently until liquefaction occurs. Then incline the vessel in different directions, in order that any portion of the iodine which may have condensed on its surface may be returned into the melted mass. Lastly, pour the melted iodide on a porcelain slab, and when it is cold break it into pieces and keep it in a well-stoppered bottle. This is the process of the U. S. P. 1870, with the iodine slightly increased in quantity, so as to correspond with the combining weights of the two elements, the union of which is readily effected by the aid of heat. The salt may be prepared in an ordinary prescription-vial placed in a sand-bath; after the fused mass has

cooled the vial is broken to obtain the compound; loss of iodine is thereby avoided. Although sufficiently pure for medicinal purposes, it is difficult to produce in this way a uniform chemical compound, which, according to Berzelius, is obtained on subjecting the mechanical mixture to sublimation from a retort the body of which is completely imbedded in sand. Or the iodine is dissolved in carbon disulphide; the solution is gently heated, and, after the gradual addition of the powdered arsenic, is digested until the purple color of free iodine has disappeared; the clear solution is decanted if necessary, and the solvent distilled or evaporated, when the arsenious iodide is obtained in crystals and may be recrystallized from alcohol.

Properties.—Obtained by fusion, iodide of arsenic is a glossy orange-red crystalline mass; if made by sublimation or crystallization it appears in shining brick-red or orange-red hexagonal scales. It has an iodine-like odor and taste, and slowly gives off iodine on exposure to the air. Its density is 4.39. It is soluble, with a neutral reaction and without decomposition, in water, alcohol, ether, and carbon disulphide, but is gradually decomposed on being boiled with water or alcohol. It is soluble in 3.5 parts of water and in 10 parts of alcohol at 15° C. (59° F.). "The aqueous solution has a yellow color, and on standing gradually decomposes into arsenious and hydriodic acids. On passing hydrosulphuric acid through the solution a lemon-yellow precipitate is thrown down. If the salt be heated with diluted nitric acid vapor of iodine is given off."—*U. S.*

Tests.—The purity is ascertained by the complete solubility of the salt in water and alcohol, and by its volatilizing on the application of heat without leaving any residue.

Off. Prep.—*Liquor arseni et hydrargyri iodidi, U. S.*

Medical Action and Uses.—The action of this medicine in small doses may be called alterative; in large doses it is an irritant poison.

The continued use of from gr. $\frac{1}{16}$ to $\frac{1}{12}$ (Gm. 0.004–0.005) twice a day occasions perspiration, with dryness of the throat and intestines; sometimes headache is complained of, but neuralgic pain in the head, if it has previously existed, may disappear. At one time it was supposed on very good authority to possess the power of preventing the development of *scirrhus tumors* of the breast, but continued observation has not confirmed the belief, although it has shown that when such tumors affect persons of a feeble and cachectic constitution their progress may be retarded by the improvement of the general health under the use of this medicine. Its influence upon certain *cutaneous diseases* is more demonstrable, particularly upon psoriasis, lepra, chronic eczema, and tinea capitis; but as identical results are obtained from arsenic alone, the influence of the iodine in the combination is very questionable. The quantity of iodine in the small dose of the compound administered ($\frac{1}{16}$ to $\frac{1}{12}$ grain) is too minute to be considered efficient. Indeed, most of the benefits said to have been derived from it were in reality obtained from mixtures of Fowler's arsenical solution with iodide of potassium in true medicinal doses. (See *ACIDUM ARSENIOSUM*.) The *dose* of iodide of arsenic should at first not exceed $\frac{1}{16}$ grain (Gm. 0.003) three times a day, and it should gradually be increased until derangement of the stomach or dryness of the throat denotes its full effect. It is best given in solution. An ointment containing 3 grains of the iodide to an ounce of lard (Gm. 0.20 in Gm. 32.00) has been used as a local application in the diseases above mentioned. Where the skin is broken it should not be employed.

ARSENICUM.—ARSENIC.

Arsenum, Arsenicum.—*Arsenic, Fr.; Arsen, Arsenik, G.*

Symbol As. Atomicity trivalent and quivalent. Atomic weight 74.9.

Origin.—Arsenic, which is classed by some chemists with the metals, by others with the non-metallie elements, is widely diffused in nature, but is found usually in small quantities. It exists in the uncombined state as *native arsenic*, known also under the name of *cobaltum* or *flystone*, but more frequently in combination with sulphur and sulphides, as *red orpiment* or *realgar*, As_2S_2 ; *yellow orpiment*, As_2S_3 ; *arsenical pyrites* or *mispickel*, $FeS_2.FeAs_2$; *cobalt-glance*, $CoS_2.CoAs_2$; *tin-white cobalt*, $CoAs_2$; and in other minerals. It was first obtained in the metallic state by Albertus Magnus in the thirteenth century by heating together white arsenic and soap.

Preparation.—On heating arsenical pyrites in earthen cylinders most of the arsenic volatilizes and is collected in iron receivers, where it congeals. $FeS_2.FeAs_2$ yields $As + 2FeS$. A portion of the arsenic remains behind with the iron sulphide, and may be recovered as arsenious acid by roasting. The crude metallic arsenic should be purified by mixing it with charcoal and subliming at the heat of a sand-bath. It is obtained on

a small scale by mixing arsenious acid with half its weight of powdered charcoal, introducing the mixture into a crucible, covering it with a layer of granular charcoal 2 or 3 inches thick, and cementing over the crucible in an inverted position another one having a small hole drilled through the bottom; on heating the crucible the arsenious acid is reduced to arsenic, which sublimes, carbonic oxide escaping; $\text{As}_2\text{O}_3 + \text{C}_3$ yields $\text{As}_2 + 3\text{CO}$.

Properties.—It is a brittle, steel-gray, crystalline mass having a bright metallic lustre, gradually changing on exposure to the air to a grayish-black color devoid of gloss. Its specific gravity is 5.73 to 5.96. Heated in a sealed tube, it fuses, but if heated in the open air it volatilizes, without melting, at a temperature of 180°C . (356°F .), a portion of it being oxidized to arsenious acid. Its vapor has a yellow color and a garlic-like odor. On immersing the metal in water the air dissolved in the latter oxidizes a portion to arsenious oxide, which explains the use of cobaltum as a fly-poison. Metallic arsenic is insoluble in simple solvents, but dissolves on heating in some fixed oils, and unites readily with most of the metals, with sulphur, chlorine, iodine, and other elements.

Compounds of Arsenic.—ARSENIOUS HYDRIDE or ARSINE, AsH_3 , is a colorless gas of a garlic-like odor and the density 2.695, and when ignited burning with a bluish flame, yielding water and arsenious oxide; but on cooling the flame, by holding in it a piece of porcelain or glass, metallic arsenic is deposited. Arsenious hydride is generated in applying Marsh's and several other tests for arsenic. (See pages 27, 28.)

ARSENIC OXIDE, As_2O_3 , is a white mass melting at a low-red heat, and at a higher heat decomposed into arsenious oxide and oxygen; in damp air or in contact with water it deliquesces to an oily-looking liquid, which is a concentrated solution of *arsenic acid*, H_3AsO_4 . This is poisonous, however, in a less degree than arsenious oxide; the concentrated solution is corrosive. It is much employed in the manufacture of certain aniline colors and for other purposes in the arts. *Pyroarsenic* and *meta-arsenic acids* are analogous to the corresponding phosphoric acids, but on dissolving in water yield at once the above *orthoarsenic acid*.

ARSENIOUS CHLORIDE, As_2Cl_3 , is a colorless, oily, very poisonous liquid, which has the specific gravity 2.205, boils at 134°C . (273.2°F .), and is by water decomposed into HCl and As_2O_3 . (See LIQUOR ACIDI ARSENIOSI.)

ARSENIOUS BROMIDE, As_2Br_3 , is formed from the two elements in the presence of carbon disulphide, like the iodide. It is colorless, crystalline, of a peculiar odor, has the density 3.66, melts at above 20°C . (68°F .), and boils at 220°C . (428°F .). It is deliquescent, and by water decomposed into As_2O_3 and HBr .

Three sulphides of arsenic are known, but the pentasulphide, As_2S_5 , is of no practical importance.

REALGAR, or RED ORPIMENT, As_2S_3 , is a mineral which consists of handsome orange-red scales. It is made by fusing together 5 parts of arsenious acid and 3 parts of sulphur, when sulphurous acid gas is given off. It burns with a blue flame, but when mixed with potassium nitrate with a brilliant white flame; a mixture for fireworks and signal-lights consists of red orpiment 2 parts, sulphur 7 parts, nitrate of potassium 24 to 26 parts.

ORPIMENT, KING'S YELLOW, or AURIPIGMENTUM, As_2S_3 , is likewise a mineral, crystallizes in prisms or scales, and is artificially obtained by fusing together 5 parts of arsenious acid with 4 to 5 parts of sulphur. It was formerly much employed as a pigment; at present it is used in fireworks, and occasionally, mixed with considerable lime, as a depilatory.

The medicinal action and uses of arsenic are treated of under ACIDUM ARSENIOSUM.

ARUM.—INDIAN TURNIP.

Wake-robin, *Dragon-root*, E.; *Gout à trois feuilles*, Fr.; *Dreiblättriger Aron*, G.

The tuber (corm) of *Arisæma* (*Arum*, *Linneë*) *triphyllum*, *Torrey*.

Nat. Ord.—*Araceæ*.

Origin.—The plant is indigenous to North America, produces one or two leaves, which are divided into three elliptical-ovate acuminate leaflets, and a green or dark-purple often striped spathe which is convolute at the base, bent hood-like at the apex, and encloses the club-shaped spadix, having the flowers sessile at the base. The fruit is a scarlet berry.

Description.—The tuber is of a depressed globular shape, with a flat and rugose base and slightly conical above. The numerous simple rootlets are attached to the upper half of the tuber, leaving the base free. It is of a brown-gray color externally, and internally white, with scattered vascular bundles. It is inodorous, and has a burning

acid taste, which it retains, to some extent, for a long time if carefully dried and preserved.

The tuberous rhizome of the European *Arum maculatum*, *Linne*, or *cuckoo-pint*, is similar in appearance, but of an oblong shape, and larger than the former: in commerce it is usually found in transverse slices or pieces which are of a mealy aspect. The starch was formerly prepared from it on the isle of Portland on the south coast of England, and used as *Portland arrow-root*.

Constituents.—The two tubers are most likely similar in composition, but their acid principle has not been obtained in an isolated state. The European arum has been analyzed by Bucholz and Enz. and the American by D. S. Jones, who proved the presence of starch, sugar, gum, albumen, resin, fat, and extractive, besides the volatile acid principle, which is soluble in ether. Enz (1858) obtained also saponin, and Bird believes that a volatile alkaloid may be present.

Allied Plants.—*COLOCASIA ESCULENTA*, *Schoff.*, s. *Caladium* (*Arum*, *Linne*) *esculentum*, *Ventenat.* and *COLOCASIA ANTIQVORVM*, *Schoff.*, s. *Arum Colocasia*, *Linne*, are extensively cultivated in many tropical and subtropical countries under the name of *coco* or *eddoes*, the thick starchy rhizomes being used for food. These and several other species are often seen under cultivation in our gardens for their ornamental foliage. All are more or less acid in the fresh state.

RICHARDIA (*Calla*, *Linne*) *ÆTHIOPICA*, *Kunth*, Egyptian calla, a well-known ornamental plant, has likewise an acid and farinaceous tuber.

Allied Drugs.—*TONGA*. A drug introduced under this name from the Fiji Islands was found by A. W. Gerrard (1880) to be a mixture of bark, leaves, and woody fibre tied into bundles by means of the inner bark of the cocoanut tree. E. M. Holmes (1880) referred the fibrous material to *Rhaphidophora vitiensis*, *Seemann*; F. von Mueller ascertained this to be correct. The plant belongs to the natural order of *Araceæ*, and is a creeper having a stem from the size of a quill to an inch or more in diameter. The scraped stem is used, and contains prismatic raphides and starch, the latter resembling arum starch. Gerrard found potassium chloride and a volatile alkaloid, *tongine*, which has not been further examined.

The bark comes from *Premna taitensis*, *De Candolle*, nat. ord. *Verbenacæ*, which is shrubby or a large tree: the inner bark is sweet and slightly astringent, and, according to Gerrard, contains a little volatile oil, sugar, pectin, and fat.

Medical Action and Uses.—The juice of the fresh plant applied to the skin may cause vesication, and when a portion of the corm is chewed, it leaves in the mouth and fauces a burning and acid taste. The acid principle, however, is dissipated by drying and by heat. In a partially dry state the corm has been used to relieve *flatulence* and *colic* and as a remedy for chronic *bronchitis*, but its virtues are not very decided. Its powder made into a paste with honey or syrup has been applied to *aphthous* sores of the mouth, and an ointment formed by stewing the fresh root with lard has been applied to *ringworm* and other local cutaneous affections. The *dose* of the powder is stated to be 10 grains (Gm. 0.60) or more. It may be administered in honey or syrup.

In 1880, Ringer and Murrell employed a liquid extract of *tonga* in the treatment of *neuralgia* with "gratifying results." They gave half-ounce doses at intervals of half an hour, and repeated them again in 2 hours without producing any effect except slight drowsiness (*Lancet*, March 6, 1880). One or two cases reported by Wallace gave similar results, although he prescribed only half-drachm doses of the fluid extract (*Med. Record*, xxii. 91). Further evidence of its virtues is desirable.

ASAFÆTIDA, U. S.—ASAFETIDA.

Assafetida, Br.; *Asa fetida*, P. G.; *Gummi-resina Asafetida*.—*Assafetida*, E.; *Asc fétide*, Fr.; *Asant*, *Stinkasant*, *Teufelsdreck*, G.

A gum-resin obtained by incision from the living root of *Ferula Narthex*, *Boissier*, s. *Narthex Assafetida*, *Falconer*, and *Ferula Scorodosma*, *Bentham et Hooker*, s. *Scorodosma fetidum*, *Bunge*. Bentley and Trimen, *Med. Plants*, 126, 127.

Nat. Ord.—*Umbelliferae*, *Orthospermæ*.

Origin.—Both plants are large perennial herbs. *Narthex*, which was discovered by Falconer in 1838, is indigenous to Western Thibet, and probably to Cashmir. It produces a stem 6 to 10 feet (2 to 3 M.) high, which is considerably branched, and bears large bipinnate leaves with large, sheathing, inflated petioles, the upper ones being destitute of laminae: the pale-yellow polygamous flowers are in solitary dense umbels, terminating the lateral branches; and the fruit is about half an inch (12 Mm.) long, dorsally flattened, with broad vittæ, and has a winged margin. *Scorodosma* was found by Lehmann (1841) in Turkestan and Bokhara, and by Bunge (1858) in Western Afghanistan. It is largely

cultivated in Northern and Western Afghanistan, and grows wild in the barren regions between the Sea of Aral and the Persian Gulf, south to Laristan. Its stem is from 5 to 7 feet (1.5 to 2 M.) high, and has but few bipinnate leaves, which are very much smaller than the large radical leaves. The numerous umbels are long-stalked and crowded at the summit of the stem, and the flat and winged fruit has very inconspicuous vittæ. *Ferula alliacea*, Boissier, of North-eastern Persia, has likewise a strong asafetida odor.

Collection.—Asafetida is obtained from the roots of both plants, which attain a considerable size, being several inches in thickness. In April, after the leaves commence to wither, a pit about 6 inches wide and 6 inches deep is dug around the root, so as to bare its upper portion, which is protected against the sun by a layer of leaves and earth, and left in this condition for about 40 days. Near the latter end of May the covering is removed, a slice of the root is cut off, and the exuded juice scraped off on the third day. The cutting of the root, which is in the mean time sheltered from the sun, is repeated twice, after which the root remains undisturbed for a week, when the same operation is repeated and a much thicker milk-juice is obtained. After another rest of several weeks the root, early in July, is again cut, and this operation is continued until the root is exhausted.

This is substantially the account of Kämpfer, who witnessed the collection of asafetida in Laristan in 1687. Dr. H. W. Bellew gives a similar account of the collection of asafetida, which he observed in 1857 near Kandahar, but it differs from the former account in the statement that the newly-sprouted radical leaves and the withered stem of the previous year are cut off from the root, in the upper bare part of which deep incisions are made, where the milk-juice concretes in tears, or, if very abundant, flows into the trench dug around the root.

Commerce.—Asafetida enters commerce by way of Bombay, to which port it is shipped from Persia and from Afghanistan, the Afghanistan drug being probably derived in part from *Narthex*, and the Persian chiefly from *Scorodosma*. It comes packed in skins and in boxes, the purest kind, which is called *hing*, being often soft, but gradually becoming hard and translucent and of a yellowish-brown or golden-yellow color. The brown variety, which comes principally from Abushaher and Bunder Abbas, is, according to W. Dymock (1875), the produce of *Ferula alliacea*, Boissier. The yellow variety is brought from Kandahar and is principally consumed in Northern India. The asafetida which reaches Bombay from Laristan is known as *anghuzeh i Lari*, and is mostly shipped abroad. The inferior qualities, the *hingra* of the Bombay market, are more or less adulterated at the place of collection, and constitute the varieties which are found in the European and American markets. The transparent *hing* may probably be obtained from the stem. In the fiscal year 1866-67, 51,869 pounds of asafetida were imported into the United States, against 173,000 pounds in 1879-80 and 78,010 pounds in 1882.

Description.—Occasionally asafetida is met with in a fluid or semi-fluid condition of a uniformly whitish color, which gradually becomes darker. Mostly, however, it forms masses of larger or smaller opaque tears of a white color internally, which are imbedded in a yellowish- or brownish-gray sticky and more or less granular mass, in which gypsum, sand, and other earthy admixtures are found. It has a strong garlicky odor and an alliaceous, acrid, and bitter taste. The tears, separated from the granular mass, are sometimes met with in the market, and should alone be used in medicine; they are externally brownish, internally milk-white; they break with a conchoidal fracture, and the surface acquires in a few hours a bright-pink color, which changes gradually to brown. Incinerated, they leave rather less than 1 per cent. of ash. When triturated with water they readily form a milk-white emulsion, which becomes yellow on the addition of potassa or soda. Ether dissolves the volatile oil and a little resin. Rubbed with strong sulphuric acid, then diluted with water and neutralized with an alkali, a slightly colored liquid is obtained which exhibits a bluish fluorescence. Exposed to cold, asafetida becomes quite brittle and readily pulverizable, and when broken into small pieces and dried for a week or two over unslaked lime in a close box it may likewise be powdered on cool days. The powder should be preserved in paper bags kept over lime, when it will retain its pulverulent condition (Hager).

A very impure asafetida is occasionally met with, which consists altogether of earthy matter mixed with a very small proportion of the milk-juice. For medicinal uses asafetida consisting of well-defined and large tears, and containing but little of the intervening sticky mass, should be selected. Asafetida should yield to alcohol at least 60 per cent. of soluble matter (*U. S.*). In contact with hydrochloric acid only slight effervescence

should be produced, and after 6 hours the acid should remain almost uncolored; when incinerated, asafetida should leave not over 10 per cent. of ash (*P. G.*).

Constituents.—The odor is due to a volatile oil which is obtainable to the amount of from 6 to 9 per cent. (Flückiger), and is a mixture of several sulphides of ferulyl or laseryl, C_6H_{11} . It is of a light-yellow color, and becomes darker on exposure to the air, acquiring at the same time an acid reaction and changing in odor. Spread upon water, it acquires a violet-red color with the vapor of bromine, at the same time becoming heavier than water; dissolved in disulphide of carbon, it is colored red by sulphuric acid (Flückiger). The gum amounts to between 20 and 30 per cent., and from 45 to 65 or 71 per cent. of the asafetida is resin, a small portion of which is insoluble in ether. It contains *ferulic acid*, $C_{10}H_{10}O_4$, which was obtained by Hlasiwetz and Barth (1866) in iridescent, inodorous, and tasteless needles soluble in boiling water, and yielding, when fused with potassa, among other products, acetic and protocatechuic acids. It dissolves in alkalies with a yellow color, and gives with ferric chloride a brown precipitate. It is chemically related to vanillin, eugenol, and cinnamic acid. The amorphous red-brown resin is likewise acid, but when fused with potassa yields resorcin, $C_6H_6O_2$, and on dry distillation furnishes a small quantity of unbelliferon, $C_9H_6O_3$, and blue-colored oils. The so-called gum of which, in Kandahar *ling*, Flückiger found 47.9 per cent. with only 10.8 per cent. of resin, is but little soluble in water; the insoluble portion dissolves in alkalies and is reprecipitated by acids; both portions differ in their behavior from gum-arabic. According to older analyses, asafetida contains also formic, acetic, valerianic, and malic acids.

Impurities.—Besides the earthy admixtures mentioned above, pieces of a translucent gum are sometimes found in asafetida; they do not yield an emulsion with water. The amount of earthy admixtures in commercial asafetida of good appearance sometimes reaches 40 per cent.

Off. Prep.—Emplast. asafetida, *U. S.*; Enema asafetida, *Br.*; Mistura asafetida, *U. S.*; Pilule aloes et asafetidae, *U. S.*, *Br.*; Pil. asafetidae, *U. S.*; Pil. asafetidae comp. (galbani comp., *U. S.*), Spiritus ammon. foetid., *Br.*; Tinct. asafetidae, *U. S.*, *Br.*

Physiological Action.—*On Animals and Man:* Experiments on animals prove the ready absorption and diffusion of the odorous principle of this substance, for when a solution of asafetida is injected into the peritoneal cavity its smell is presently detected in the blood and the breath. Asafetida in substance, or its volatile oil, acts as a general and local stimulant, but during health the former operation is scarcely perceptible. This stimulation seems to be due entirely to this oil, and so is the peculiar garlicky or alliaceous odor exhaled by the breath and discharges of wind from the stomach and rectum. But in appropriate disorders, those especially connected with a depressed and therefore excitable condition of the nervous system, and in cases of gastro-intestinal flatulence associated with atony of the bowels, it displays incontestable and highly salutary powers. Its use as a condiment in Persia for the very same purposes for which garlic is employed in European cookery proves it to be a stimulant of the bowels and a promoter of digestion.

Medical Uses.—Asafetida is generally regarded as a nervine and as remarkable for its usefulness in *hysteria*. In two ways it may influence this disease: by allaying the nervous disorder of the paroxysm when it is announced by premonitory symptoms, or by moderating its violence when fully formed; and, on the other hand, by tending to correct some of those derangements which predispose to the attacks. In the former way, however, its influence is most distinct. For this purpose it is best exhibited in enema. It is also of use in preventing or in mitigating the tympanites which is so common in hysteria. In the allied disorder, *hypochondriasis*, the medicine is often of service in removing the digestive ailments with which the mental disorder is apt to be associated. In *chronic bronchitis* attended with spasmodic dyspnoea it is probable that asafetida both diminishes the secretion in the lungs and controls the spasmodic element. The latter action is sometimes evident in *whooping cough*, and possibly both actions may concur. When *constipation* and *tympanites* are met with, as they often are, in persons of a feeble and nervous habit, this medicine is one of the very best that can be employed, either as a temporary remedy for the latter symptom or as a more permanent cure for the former when combined with appropriate purgatives, of which aloes is the best. The compound pills of galbanum, which contain also myrrh and asafetida, are exceedingly useful under these circumstances. But in tympanites a large enema of asafetida mixture often gives prompt and complete relief. This condition, when it occurs in typhoid fever, may be greatly reduced by such an enema, which also acts favorably upon the typhoid element of the disease. The exhausted condition of the nervous system and the partial paralysis which often follow *nervous apoplexy* may be removed more or less by the same means, as well as by adminis-

tering the drug by the mouth. Asafetida should not be neglected in *chorea* occurring in feeble, nervous girls about the age of puberty, particularly when the nervous disorder is accompanied with tardy or irregular menstruation.

Administration.—In substance the dose of asafetida is from 3 to 15 grains (Gm. 0.20–1.00). It should be given in pill or in the official mixture. For prompt effect the latter form or the tincture is to be preferred.

ASARUM.—WILD GINGER.

Radix asari canadensis.—*Canada snakeroot*, E.; *Assaret du Canada*, Fr.; *Canadische Haselwurzel*, G.

The rhizome with rootlets of *Asarum canadense*, *Linne*.

Nat. Ord.—Aristolochiaceæ.

Origin.—The plant is indigenous to North America, growing in rich woodlands as far south as South Carolina, but is more frequent in the States farther north and in Canada. The creeping rhizome sends up a very short stem, bearing at its summit two broad reniform leaves upon petioles about 6 or 8 inches (15 or 20 Cm.) in length, from the fork of which a single brownish-purple nodding flower is produced.

Description.—The rhizome, which is in some places known as *colt's-foot-root*, is from 3 to 6 inches (7 to 15 Cm.) long and about $\frac{1}{8}$ inch (3 Mm.) thick, somewhat bent and curved and with few branches. It is finely wrinkled longitudinally; the internodes are about half an inch (12 Mm.) or more in length, the nodes often of a jointed appearance from the remnants of leaves, and beset with several thin nearly simple radicles 2 or 3 inches (50 to 75 Mm.) in length. Externally the color is deep purplish-brown, internally whitish. The bark is about one-sixth the diameter of the rhizome, and contains volatile oil in many of its parenchyma-cells; the wood is in about twelve small wedge-shaped bundles, forming an interrupted circle and enclosing a large pith. The rootlets have a thick bark and a thin, soft woody cord. Wild ginger has an aromatic odor and a warm, pungent, and bitterish taste. It resembles *asarabacca*, the rhizome and rootlets of *Asarum europæum*, *Linne*; the latter, however, is always thinner, about $\frac{1}{16}$ or $\frac{1}{12}$ inch (1.5 to 2 Mm.) in diameter, and usually quadrangular in the dry state.

ASARUM SIEBOLDII, *Miquel*. This plant grows in Japan, where it is known as *to-sai-shin*. The slender rhizome somewhat resembles serpentry, is marked by numerous stem-scars, and has dense tufts of pale-brown simple rootlets attached, which are about 4 inches (10 Cm.) long, and are internally mealy, white, and with a thin yellow ligneous cord. The drug has a slight aromatic odor and a taste which is at first aromatic, resembling a mixture of nutmeg and saffron, and afterward very pungent and irritating.

Constituents.—Wild ginger contains a yellowish volatile oil and an acrid bitter resin, to which its medicinal properties are probably due. Van Gorder (1876) obtained 2 per cent. of aromatic volatile oil and a neutral resin having a different agreeable odor and a pungent, warm, and lasting taste. It also contains starch, gum, fixed oil, coloring matter, and salts. F. B. Power (1880) ascertained also the presence of a yellow coloring matter corresponding to Graeger's *asarin*, which is precipitated by basic lead acetate and colored dark-green by ferric salts, but not precipitated by tannin. A minute quantity of a body was found giving precipitates with most group-reagents for alkaloids. The volatile oil, of which Dr. Squibb obtained 3.12 per cent., had the specific gravity .953 at 17° C. (62.6° F.). It is of a yellowish- or greenish-amber color, and consists of a very small amount of *asarene*, $C_{10}H_{16}$, of the acetic and a small amount of the valerianic ether of *asarol*, $(C_{10}H_{15}O)_2$, of an indifferent neutral body, *asarin*, $C_{12}H_{16}O_2$, and of a small amount of dark-blue azulene. The volatile oil has been introduced for use in perfumery, and, according to Boerner (1878), is also adapted for the preparation of a medicated water and for flavoring elixirs. The fully-dried root yielded 13.43 per cent. of ash.

The impure bitter principle of *asarabacca* has been named *asarin*. The camphor-like bodies *asaron* and *asarit* appear to be chemically identical, differing only in the latter separating from the watery distillate in fine crystals, while asaron or *asarum* camphor separates first in an oily condition before it crystallizes. It is inodorous and tasteless, has the composition $C_{20}H_{36}O_3$, and volatilizes with the production of irritating vapors.

Medical Action and Uses.—*Canada snakeroot* is an aromatic and tonic stimulant. In hot infusion it is diaphoretic; it palliates *colic*, and is sometimes used in low forms of *febrile disease* as a substitute for *serpentaria*. An infusion may be made with half an ounce (Gm. 16) of the root and a pint of boiling water, and given in doses of a wine-glassful. The European species of *asarum* is not official. It is much more irritating

than the native plant, producing violent vomiting and purging. The powder of its root is employed as an emetic.

ASCLEPIAS, U. S.—ASCLEPIAS.

Pleurisy-root, E.; *Racine d'asclépiade tubéreuse*, Fr.; *Knollige Schwalbenwurzel*, G.

The root of *Asclepias tuberosa*, Linné.

Nat. Ord.—Asclepiadaceæ.

Origin.—This perennial plant, which is known also as *butterfly-weed* and *orange scallow-weed*, is a native of the United States south to Georgia and west to Texas, and grows in sandy fields. The large fusiform, tuberous root sends up several rather weak and branching hirsute stems, with alternate lanceolate or lance-linear leaves and a terminal corymb of numerous umbels, the flowers being of a handsome bright orange-red color.

Description.—The root is usually found in the market in pieces from 1 to 6 inches (2 to 15 Cm.) in length, and $\frac{1}{2}$ to 1 inch (12 to 25 Mm.) or more thick. The head is irregular, knotty, and slightly but closely annulate, and like the longitudinally wrinkled root, externally of a brownish-orange color and white or yellowish-white within. It has an irregular, tough fracture, a very thin bark (composed of an outer brownish and an inner white layer) and a distinctly striate medullium composed of yellowish ligneous and large white medullary rays. It is inodorous and has a bitterish, slightly acrid taste. When long kept it acquires a gray color externally and internally.

Constituents.—Besides starch, which is present in considerable proportion, the root contains, according to Elam Rhoads (1861), tannin, albumen, pectin, gum, two resins—one soluble, the other insoluble in ether—fixed oil, an odorous volatile matter, and a peculiar principle possessing the taste of the root, which is precipitated by tannin from the concentrated infusion. This precipitate, if decomposed by oxide of lead and exhausted by alcohol, yields the principle as a yellowish-white powder which is soluble in alcohol, ether, and much water. Alton Clabaugh (1881) observed that this principle is colored brown by sulphuric acid, and pink, changing to purple, by nitric acid. The stearopten melted at 41° C. (106° F.), and was sublimable in prismatic needles. The air-dry root yielded 5.4 per cent. of ash, of which 21.5 per cent. was soluble in water.

Allied Plants.—1. *ASCLEPIAS INCARNATA*, Linné.—Flesh-colored *asclepias*, Swamp milkweed, E.; *Asclépiade incarnate*, Fr.; *Fleischfarbige Schwalbenwurzel*, G.—The plant is indigenous to Canada and to the United States as far south as South Carolina. It grows in wet grounds, and consists of a smoothish or pubescent stem about 3 feet (.9 M.) high, bearing petiolate oblong-lanceolate and acute leaves, umbels of rose-purple flowers, and smooth pods. The variety named *pulchra* has shorter petioles and broader hairy leaves. The rhizome is irregularly globular, an inch (25 Mm.) or less in diameter, above with several more or less elongated branches, bearing the scars of the over-ground stems and frequently remnants of the same. Externally the color is yellowish-brown, internally whitish. The bark is thin, and covers a firm wood having fine medullary rays. The rhizome is surrounded on all sides with nearly simple light-brownish rootlets about 4 to 6 inches (10 to 15 Cm.) long, having a thick white bark and a thin ligneous cord in the centre. In the fresh state the rhizome has a somewhat heavy odor, which is but slightly apparent after drying; the taste is sweetish, somewhat acrid, and afterward bitter.

Examined by Jos. Y. Taylor (1875), the root contains a trace of volatile oil, two acrid resins, an alkaloid which was not obtained in the pure state, fixed oil, albumen, pectin, starch, glucose, and yields 8.25 per cent. of ash.

2. *ASCLEPIAS CORNUTI*, Decaisne, s. A. SYRIACA, Linné.—Milkweed, Common silkweed, Wild cotton, E.; *Asclépiade à la soie*, *Herbe à la ouate*, Fr.; *Schwalbenwurzel*, *Seidenpflanze*, G.—The rather stout and smoothish stem of this common plant, which is indigenous to Canada and the United States, is about 3 or 4 feet (.9 or 1.2 M.) high, nearly simple, and bears oval-oblong acute and shortly petiolate opposite leaves, which are about 6 to 8 inches (15 to 20 Cm.) long, and three or four axillary umbels near the summit of the stem, with numerous sweet-scented, light greenish-purple flowers. It grows along roadsides and in waste places. The rhizome is horizontal, a foot (30 Cm.) or more in length, slightly branched, $\frac{1}{4}$ to 1 inch (6 to 25 Mm.) thick, externally grayish-brown, finely wrinkled longitudinally, beset with few simple rootlets or marked with their scars, but often tuberculated or knotty from undeveloped branches or stem-scars. When dry it breaks with a short fracture, exhibiting a thick white bark containing slender milk-vessels, and a soft, brittle, porous, yellowish wood dissected by rather broad medullary rays. It is without odor and has a bitterish, unpleasant taste. The parenchyma contains starch. John found in the milk-juice of the plant caoutchouc and resin, and List separated from it (1849) a white, crystalline, tasteless principle, *asclepin*, having the composition $C_{20}H_{34}O_3$, by exhausting the congealed milk-juice with ether. Sultz found (1845) in 80 parts of the milk-juice 69 water, $3\frac{1}{2}$ wax and fat, 5 caoutchouc, $\frac{1}{2}$ gum, and 2 sugar and salts. W. L. Hinchman (1881) ascertained also the presence in the rhizome of a little volatile oil, tannin, gummy matter, and a bitter principle

which was not obtained in the pure state; the fresh rhizome appears to contain a volatile acrid principle.

3. *ASCLEPIAS CURRASAVICA*, *Linneé*.—This perennial herb is indigenous to South America and the West Indies. The root, known as *bastard ippecuanha* (see *IPPECACUANHA*), and the leaves are used. The latter are petiolate, 2 to 4 inches (5 to 10 Cm.) long, lanceolate or oblong-lanceolate, acute at both ends, and smooth. The flowers are bright-red, occasionally white. The glossy seed-hairs, sometimes called *vegetable silk*, are firmer than those of the preceding species.

4. *CALOTROPIS* (*ASCLEPIAS*, *Willdenow*) *GIGANTIA*, *Rob. Brown*, and *Cal. procera*, *R. Brown*, s. *Cal. Hamiltonii*, *Wight* (*Bentley and Trimen, Med. Pl.*, 176), are shrubs 6 to 10 feet (2 to 3 M.) high, the former being indigenous to Southern India and the East Indian Islands, the latter to Northern India and westward through Asia and tropical Africa. Both species yield *mular-bark*, which consists of irregular fragments $\frac{1}{2}$ inch (5 Mm.) or less thick, externally yellowish-gray, fissured, or after separation of the corky layer whitish, and upon the transverse section striate with the narrow brown bast-rays. The bark is brittle, of a slight odor, and of a mucilaginous bitter and acrid taste, and has often attached to it fragments of the light-yellow fibrous wood. It contains starch, an acrid acid resin soluble in alcohol and ether, and a colorless bitter principle soluble in alcohol, ether, and chloroform and precipitated by tannin, but not by lead acetate (*Pharmacographia*).

Medical Action and Uses.—The qualities of the three species of *Asclepias* are practically identical, but those of *A. tuberosa* are best known. Like many other medicines, it has been alleged to possess specific powers in the cure of particular diseases, but a comparison of the reports concerning it show that it is one of the numerous class of vegetable products which under certain conditions act as emetics, and even purgatives, and more commonly as sudorifics, expectorants, carminatives, and anodynes. Being an irritant, it has not escaped being ranked as a cholagogue. *A. syriaca* is said to be diuretic. Its general qualities account for the reputation of the officinal plant as a diaphoretic in the forming stage of *fevers*. It is, however, thought to produce sweating, not by stimulating but by lowering the action of the heart. The same characteristic renders it useful in acute *rheumatism*, *bronchitis*, *pneumonia*, and *pleurisy*, so far as sedation of the nervous and circulatory systems can be so; that is, by lessening local congestions. The “pleurisy” it is credited with relieving was most probably muscular rheumatism of the walls of the chest. Flatulent *colic* and *dyspepsia* are affections to which it has been regarded as peculiarly appropriate. The milky juice of *A. syriaca*, applied to the skin, soon becomes a tough, adhesive pellicle, and has been used to coat recent *wounds* and superficial *ulcers* and promote their cicatrization. The *dose* of the powdered root is from 20 to 60 grains (Gm. 1.30–4.00). A decoction is made with an ounce (Gm. 32) of pleurisy-root to a quart of water, and is given in doses of 4 fluidounces every 2 hours as a diaphoretic. A fluid extract has also been prepared.

In 1881, Dr. Guimaraes described the physiological action of *A. curassavica*, a native of Brazil. He found it to act directly upon the organic muscular system, and especially upon the heart and blood-vessels, causing great constriction of the latter and distension of the larger arteries. Secondly, it occasioned great dyspnoea, vomiting, and diarrhoea (*Times and Gaz.*, Dec. 1881, p. 661).

ASPARAGUS.—ASPARAGUS.

Asperge, Fr.; *Spargel*, G.

Asparagus officinalis, *Linneé*.

Nat. Ord.—Liliaceæ, Asparagineæ.

Origin and Description.—This herbaceous perennial is indigenous to Europe, and is extensively cultivated. Its stem is 4 or 5 feet (1.5 M.) high, has the thread-like leaves (branchlets, *Gray*) clustered in the axil of a short, ovate sheathing bract (leaf, *Gray*), and small, greenish, axillary, nodding flowers, producing red berries. The following parts have been medicinally employed:

1. *ASPARAGI RADIX* consists of a short horizontal rhizome about three-quarters of an inch (19 Mm.) thick, on the upper side marked by stem-scars, and below by numerous long, whitish, nearly simple roots, which on drying become deeply wrinkled longitudinally. It is inodorous and has an insipid sweetish taste.

2. *ASPARAGI TUBERONES*, the well-known young shoots which are used as food.

Constituents.—Examined by Dulong, the root was found to contain yellow resin, sugar, gum, albumen, chlorides, phosphates, malates, and acetates. Vauquelin and Robiquet (1805) discovered *asparagin* in the shoots, which has since been found in many other plants (see p. 162). Reinsch (1870) found in the berries considerable grape-sugar and

spargancin, an orange-red sublimable coloring matter soluble in ether and crystallizing in scales. The seeds contain fixed oil, aromatic resin, crystallizable sugar, and a crystallizable bitter principle, *spargin*.

Pharmaceutical Uses.—*SYRUPUS ASPARAGI*, which is employed in France, is prepared by dissolving 190 parts of sugar in 100 parts of the clarified juice of asparagus-shoots.

The tubers of *Asparagus ascendens*, *racemosus*, and *sarmentosus*, *Linneé*, are employed in India like salep.

Medical Uses.—The offensive odor given to the urine of persons who eat the young asparagus-plant is well known; some attribute to it a diuretic virtue which there is no reason to accept; others have reported that it may cause urethritis; and one, at least, that it renders the urine saccharine. If any part of the plant is diuretic, it is probably the root. It has no true medicinal virtues.

ASPIDIUM, U. S.—ASPIDIUM.

Filix mas, Br., U. S. 1870; *Rhizoma filicis*, P. G.; *Radix filicis maris*.—*Male fern*, *Male shield fern*, E.; *Rhizome (Racine) de fougère mâle*, Fr.; *Wurmfarnwurzel*, *Waldfarnwurzel*, *Johanniswurzel*, G.

The rhizome, covered with portions of the stipes, of *Aspidium* (*Nephrodium*, *Brown*, *Polypodium*, *Linneé*) *Filix mas*, *Swartz*, and of *Aspidium* (*Nephrodium*, *Michaux*, *Polypodium*, *Linneé*) *marginale*, *Willdenow*. *Woodv.*, *Med. Bot.*, plate 271; *Bentley and Triemen*, *Med. Plants*, 300.

Nat. Ord.—Filices.

Origin.—Male fern is indigenous to Canada westward to the Pacific Ocean, thence south along the Rocky Mountains to Mexico and a considerable portion of South America;

to some of the Polynesian Islands; to the greater portion of Asia north of the Himalaya Mountains; and to Europe and some parts of Africa. The marginal shield fern grows in rich rocky woods in Canada and the United States. The fronds of both species are from 1 to 2 or 3 feet (30 to 60 or 90 Cm.) high, bipinnate, at the tip pinnate or pinnatifid, lanceolate, or the latter ovate-lanceolate in outline and evergreen; the circular fruit-dots are situated on the veins—in the male fern near the midrib of the lower half of the pinnules, or in the marginal shield fern at the base of the serratures along the margin of the lower side of the pinnules, and are covered with an orbicular heart-shaped indusium. The fronds arise from the living somewhat ascending end of the horizontal rhizome,

FIG. 34.

FIG. 33.

Aspidium: surface of peeled rhizome.

Aspidium Filix mas, *Sw.*: transverse section of rhizome; *f*, fibro-vascular bundles.

which is 6 to 12 inches (15 to 30 Cm.) long, and the old portion densely covered with the remnants of the stipes. It is collected early in autumn or in summer, as directed by the *British Pharmacopœia*.

Description.—As found in commerce, it is 3 to 6 inches (7 to 15 Cm.) long, and with the closely imbricated and slightly curved remnants of the stipes 2 to 3 inches (50 to 75 Mm.) thick. The latter remain green in their lower portion for several years, and are, like the rhizome itself, densely covered with a brown, glossy, and soft chaff consisting of thin transparent scales; between the stipes are the black wiry rootlets. The rhizome itself is fleshy, $\frac{1}{2}$ to 1 inch (12 to 25 Mm.) in diameter, externally dark-brown, internally of a pale-green color and spongy texture, and shows upon the transverse section near the surface eight to twelve larger fibro-vascular bundles arranged in an interrupted circle, outside of which are a number of smaller ones. The stipes have about eight small vascular bundles in a loose circle. The rhizome of the marginal shield fern corresponds with this description in all respects, except that it has about six fibro-vascular bundles and does not fully attain the diameter of the thickest male fern rhizomes. The spongy texture is due to the thin-walled parenchyma and to the large intercellular spaces, into which stalked glands project which exude a green liquid. These glands were observed in male

fern by Herman Schacht (1863), and in marginal shield fern by Flückiger (1880); many allied species do not contain such glands. *Aspidium* has a slight disagreeable odor and a sweetish afterward somewhat bitter astringent and nauseous taste. For medicinal purposes the dead portions of the stipes and rhizome must be removed, and the green part only retained, which should be at once dried, powdered, and exhausted by ether for preparing the oleoresin.

Constituents.—Male fern has been frequently analyzed. Geiger (1826) obtained 6.9 per cent. of green fixed oil, which Luck (1851) found to consist of the glycerides of *filicolic* and *filosmylic* acids, the last of which is volatile. The tannin of older authors was separated by Luck into two acids, *tannaspidic* and *pteritannic* acids, the last only being soluble in ether, both coloring ferric salts green. Malin (1867) found only one tannin, *filitannic* acid, which on being boiled with dilute sulphuric acid is split into sugar and *filic-red*, the latter in an impure condition, being Luck's tannaspidic acid. Peschier (1826) obtained from the ethereal extract granular crystals, which Luck named *filicic acid*. Grabowski (1867) gave it the formula $C_{14}H_{16}O_5$, and found it to be *dibutyryl-phloroglucin*, which is decomposed by potassa near the fusing-point into phloroglucin and butyric acid. Pavesi's *aspidin* (1861) is a very impure filicic acid, which is probably the main active ingredient. Boek (1851) determined the tannin to amount to 10 per cent., and found also a trace of volatile oil, wax, chlorophyll, gallic acid, albumen, pectin, starch, gummy matter, sugar, and 2 to 3 per cent. of inorganic salts. J. L. Patterson (1875) obtained from the rhizome of the marginal shield fern filicic acid and a tannin similar to, if not identical with, that of filix mas; and C. H. Cressler (1878) found the oleoresin effectual in several cases of tape-worm.

Allied Drugs.—*ASPIDIUM RIGIDUM*, Swartz. This fern grows on the eastern slope of the Coast Range of California and in the alpine regions of Europe. The stipe-bases are only loosely imbricated, and, after these, the brown chaff, and the numerous wiry rootlets are removed, leave a pale-green rhizome 4 to 10 inches (10 to 25 Cm.) long, $\frac{2}{3}$ to $\frac{1}{2}$ inch (1 to 2 Cm.) thick, and having about six broad fibro-vascular bundles in a circle: its odor is somewhat aromatic. W. J. Bowman (1881) ascertained its constituents to be analogous to those of the above species. It is used in California like male fern.

ASPIDIUM ATHAMANTICUM, Kunze, is indigenous to the southern part of Africa, from Natal to Angola. The rhizome is known as *uncomocomo* or *patuna-root*, is thicker and denser than male fern, often densely covered with dark-brown stipes and red-brown chaff, and is internally pale-brownish, showing numerous black resin-dots and a circle of ten to thirteen large and small fibro-vascular bundles.

ASPLENIUM THELYPTEROIDES, Michaux, of North America, has a rhizome resembling the next.

ASPLENIUM LILIX FEMINA, Bernhardt, has a thin rhizome, which is densely covered with black, thin, almost two-edged remnants of the stipes, and has numerous black roots, but little scaly chaff. Analyzed by Boek (1851), the constituents were found to be similar to those of male fern; the presence of filicic acid has not been shown.

ASPIDIUM SPINULOSUM, Swartz, has a thin rhizome, with about six small fibro-vascular bundles, and with dark-brown nearly cylindrical stipe-remnants, between which little or no chaff is found.

OSMUNDA REGALIS, Linné. The rhizome is about half an inch (12 Mm.) thick, densely covered with numerous brown stipe-remnants, and of a mucilaginous, slightly bitter taste.

POLYPODIUM VULGARE, Linné (Meehan, *Nat. Flowers*, ii. 161). The rhizome is thin, flattish, with rather distant and very short stipe-remnants on the upper side, and with hair-like roots on the lower side. Desfosses (1828) found in it fat, starch, gum, sugar, a glutinous substance, albumen, astringent, extractive, malic acid, and salts.

The last four species are indigenous to Europe and North America.

Medical Action and Uses.—Male fern was anciently known to be a remedy for *tænia* and other intestinal worms, but its reputation was more firmly established in the last century. It is more efficacious in removing the unarmed than the armed *tænia*, unless the latter be young. The methods employed by different physicians in the treatment of *tænia* by male fern are for the most part very complicated, and seem devised more in a spirit of charlatanism than of art. It is, as a rule, essential that the bowels should contain no accumulation of partially-digested food or of feces, and that the vigor of the parasite should be reduced by as low and simple a diet as can well be borne, and chiefly in a liquid form, as milk or broth. Early in the morning, fasting, the patient should take from 30 to 90 grains (Gm. 2–6) of powdered male fern, at a single dose or in divided doses at short intervals. The oleoresin of male fern, in the dose of from 10 to 20 drops (Gm. 0.60–1.30), may be administered along with the powdered root, or in feeble persons by itself. About an hour after either preparation an active purge of calomel with jalap

or gamboge is sometimes administered, but generally an ounce of castor oil will suffice. Some prefer Epsom salts. It is by certain authorities recommended to give a full dose of sulphuric ether shortly after the specific medicine, for the purpose of rendering the detachment of the parasite easier. The oleoresin is conveniently administered in gelatin capsules. The dose of filicic acid is about 30 grains (Gm. 2).

Aspidium marginale appears to possess the same properties as male fern. Suesseroth employed a fluid extract of it in the treatment of *tænia* with entire success (*Trans. Med. Soc. Penna.*, 1875, p. 637), and Cressler, who gave the oleoresin in capsules containing each about 10 minims, caused the expulsion of *tænia* on two occasions. The usual associate treatment of abstinence from food before the medicine and a purgative after its administration was also carried out (*Amer. Jour. Pharm.*, June, 1878).

ATROPINA, U. S.—ATROPINE.

Atropia, Br.; *Atropinum*.—*Atropia*, E.; *Atropine*, Fr.; *Atropin*, G.

Formula $C_{17}H_{23}NO_3$. Molecular weight 289.

Preparation.—Take of Belladonna-Root, recently dried and in coarse powder, 2 pounds; Rectified Spirit 10 pints; Slaked Lime 1 ounce; Diluted Sulphuric Acid, Carbonate of Potash, each a sufficiency; Chloroform 3 fluidounces; Purified Animal Charcoal a sufficiency; Distilled Water 10 fluidounces. Macerate the root in 4 pints of the spirit for 24 hours, with frequent stirring. Transfer to a displacement apparatus, and exhaust the root with the remainder of the spirit by slow percolation. Add the lime to the tincture placed in a bottle and shake them occasionally several times. Filter, add the diluted sulphuric acid in very feeble excess to the filtrate, and filter again. Distil off three-fourths of the spirit, add to the residue the distilled water; evaporate at a gentle heat, but as rapidly as possible, until the liquor is reduced to one-third of its volume and no longer smells of alcohol: then let it cool. Add very cautiously, with constant stirring, a solution of the carbonate of potash, so as to nearly neutralize the acid, care, however, being taken that an excess is not used. Set to rest for 6 hours, then filter, and add carbonate of potash in such quantity that the liquid shall acquire a decided alkaline reaction. Place it in a bottle with the chloroform, mix well by frequently-repeated brisk agitations, and pour the mixed liquids into a funnel furnished with a glass stopcock. When the chloroform has subsided, draw it off by the stopcock, and distil it by a water-bath from a retort connected with a condenser. Dissolve the residue in warm rectified spirit; digest the solution with a little animal charcoal; filter, evaporate, and cool until colorless crystals are obtained.—*Br.*

The British process is that proposed by Mein, except that the alkaloid, instead of being simply precipitated from the watery solution of its sulphate, is removed by agitation with chloroform, in accordance with the suggestion of Rabourdin (1850). The lime, on being agitated with the tincture of the root, removes considerable resin and fat, the little lime which enters into solution being afterward precipitated by sulphuric acid as sulphate of calcium, while the atropine remains in the liquid as sulphate, which is readily soluble in alcohol and water. On neutralizing the free acid with carbonate of potassium another quantity of resin is separated, and on rendering the liquid alkaline the atropine is set free, and is taken up by the chloroform on being agitated with it. Treatment with alcohol and animal charcoal is resorted to for the purpose of removing the last traces of coloring matter and obtaining the alkaloid crystallized.

A process similar to the preceding was proposed by Prof. Wm. Procter, Jr., in 1860, who, after treating the tincture with lime and sulphuric acid and evaporating the alcohol, as described above, removed most of the remaining oil and resin by diluting the residue with water, filtering, and agitating with chloroform, in which the sulphate of atropine is insoluble; after the addition of caustic potassa, chloroform was used for extracting the alkaloid, of which 0.39 per cent. was obtained in a crystalline condition and of a fawn color, which was removed by treating the alcoholic solution with animal charcoal. The process of the U. S. P. 1870 arrived at the same result by converting the alkaloid contained in the tincture of belladonna-root into a sulphate. After most of the alcohol had been distilled off, the residuary liquid was poured into water, which retained the sulphate of atropine in solution, while nearly all the resin and oil was separated and removed by filtration. By means of potassa and chloroform the alkaloid was obtained, on evaporating the latter, in yellowish crystals, which, although then considered sufficiently pure for

medicinal purposes, contain variable amounts of impurities; these, however, are removed without much trouble and loss by recrystallization from alcohol of 50 per cent.

In all the above-mentioned processes it is of importance that the treatment with the alkalies and alkaline carbonate should take place at a low temperature and not be unnecessarily prolonged, since carbonate of potassium alters the atropine and renders it inert when acting upon its aqueous solution at an elevated temperature; caustic potassa effects a similar decomposition already in the cold during a contact for 24 hours.

Properties and Tests.—Pure atropine is in colorless or white, glossy acicular crystals without odor, and has a disagreeably bitter and acrid taste. It melts at 113.5° C. (236.3° F.), according to Ladenburg (1880); at 115.5° C. (240° F.), according to E. Schmidt (1881); when carefully heated it volatilizes at 140° C. (284° F.), partly unchanged, and at a higher heat is completely decomposed, leaving no residue. It is soluble in 300 parts (Von Planta), 500 parts (Geiger), 600 parts (*U. S. P.*), of water at 15° C. (59° F.), and in 35 parts (*U. S. P.*), or on continued boiling in 30 parts of boiling water (Geiger and Hesse). It is very freely soluble in alcohol, dissolves in warm oil of turpentine; according to Geiger and Hesse, in 63 parts (36 parts, Brandes) of ether, in 3 parts of chloroform, 38 parts of olive oil, also in 50 parts of glycerin. It has a strong alkaline reaction and neutralizes acids, forming salts which are crystallizable with difficulty and are soluble in water and alcohol, but insoluble in ether and chloroform. The solutions of the salts are not precipitated by platonic chloride except when very concentrated; their characteristic reactions, according to Ladenburg, are the following: With tannin, a white precipitate soluble in diluted acids; with iodine, a brown oily precipitate, becoming crystalline; with potassio-mercuric iodide, a white curdy precipitate; with pieric acid, a crystalline precipitate; with chloride of gold, a yellow oily precipitate, crystallizing after some time, the dry crystals melting at 135° C. (275° F.), and when recrystallized from boiling diluted hydrochloric acid are again deposited in minute crystals, and after drying form a dull, lustreless powder (difference from hyoscyamine); the alcoholic solution of atropine, on passing cyanogen gas through it, becomes blood-red (Hinterberger, 1851); warmed with sulphuric acid and potassium bichromate after the addition of water, atropine develops a pleasant benzoin-like odor, the liquid becoming green (Ludwig, 1861); with cold sulphuric acid it yields a colorless solution, and on warming gives an odor resembling orange-flowers (Gulielmo, 1863). The sulphuric acid solution is not colored red by nitric acid (difference from morphine, narcotine, etc.), nor blue or purple by bin-oxide of manganese or potassium bichromate (difference from strychnine); the last-named reagent causes a green color.

When heated with baryta-water, soda, or strong hydrochloric acid, atropine is decomposed, yielding tropic acid, $C_9H_{10}O_3$ (by continued action atropic and isatropic acids, $C_9H_8O_2$), and tropine, which is a crystallizable, strongly alkaline compound having the formula $C_8H_{15}NO$ (Kraut, 1863; Lossau, 1864); it crystallizes in white hygroscopic needles or plates, is freely soluble in water, alcohol, and ether, and may be distilled in a current of hydrogen. Tropic tropate has no effect on the eye, but when heated with excess of dilute hydrochloric acid in a water-bath separates at first an oil, and when now treated with potassium carbonate yields atropine (Ladenburg, 1879).

According to Hübschmann (1858), commercial atropine frequently contains an uncrystallizable alkaloid, *belladonnine*, which is sparingly soluble in water and has a faintly bitter, burning, acrid taste. It may be removed from atropine by adding to the watery solution of the salt a small quantity of carbonate of potassium, when it is precipitated before any atropine is liberated; its identity with hyoscyamine has been suggested by Ladenburg. But Buchheim (1876) stated that it is decomposed by alcoholic potassa (not by barium hydrate) into tropine and *belladonnine acid*. In 1850, Von Planta stated atropine to be chemically identical with daturine, the alkaloid of stramonium; and since that time it is said the latter alkaloid has not unfrequently been manufactured and sold as atropine, notwithstanding the researches of Von Schroff and others have proved it to exert a more powerful physiological action than the latter. Ladenburg (1880) has shown that after the removal of belladonnine the product from belladonna consists of atropine, described above, and a small quantity of light atropine or hyoscyamine, while daturine is a mixture of the same two alkaloids, but hyoscyamine predominating.

Apatropine, $C_{17}H_{21}NO_2$, according to Pesci (1882), is obtained by treating atropine with fuming nitric acid, and is converted into *hydro-apatropine*, $C_{17}H_{19}NO_2$, by treatment with sodium-amalgam.

Off. Prep.—Atropiæ sulphas, Liquor atropiæ, Unguent. atropiæ, Br.

ATROPINÆ SULPHAS, U. S.—SULPHATE OF ATROPINE.

Atropia sulphas, Br.; *Atropinum sulfuricum*, P. G.—*Sulphate of atropia*, E.; *Sulfate d'atropine*, Fr.; *Atropinsulfat*, *Schwefelsaures Atropin*, G.

Formula $(C_{17}H_{23}NO_3)_2H_2SO_4$. Molecular weight 676.

Preparation.—Take of Atropia 120 grains: Distilled Water 4 fluidrachms: Diluted Sulphuric Acid a sufficiency. Mix the atropia with the water and add the acid gradually, stirring them together until the alkaloid is dissolved and the solution is neutral. Evaporate it to dryness at a temperature not exceeding 37.7° C. (100° F.).—Br.

In preparing this salt it is important that the acid be very carefully neutralized, and that in evaporation the heat be cautiously applied. The salt is left behind in an amorphous condition, but may be obtained crystalline by dissolving it in absolute alcohol and evaporating spontaneously, or by pouring this solution into anhydrous ether. Ch. Maitre (1856) proposed a process which was recognized in the U. S. P. 1870. The atropine is dissolved in anhydrous ether, and sulphuric acid diluted with strong alcohol is carefully dropped in until the liquid just acquires a permanent acid reaction; the precipitate is washed with a little ether and dried at a low temperature.

Properties.—Atropine sulphate is "permanent in the air, odorless, having a very bitter, nauseating taste and a neutral reaction; soluble in 0.4 part of water and in 6.5 parts of alcohol at 15° C. (59° F.); very soluble in boiling water and in boiling alcohol; also soluble in 0.3 part (30 parts, Hager) of absolute alcohol. When heated on platinum-foil the salt is decomposed and wholly dissipated, emitting acrid vapors. On adding test solution of carbonate of sodium to a concentrated aqueous solution of the salt a white precipitate is obtained, which answers to the reactions of atropine. (See ATROPINA.) The salt or its solution when applied to the eye strongly dilates the pupil. An aqueous solution of the salt yields with test solution of chloride of barium a white precipitate insoluble in hydrochloric acid."—U. S. "It is soluble in 3 parts of alcohol sp. gr. 832, in 1 part of water, and is insoluble in ether and in chloroform. Heat .001 Gm. of it in a test-tube until white vapors are visible; then add 1.5 Gm. sulphuric acid; heat again until the mixture begins to turn brown, and dilute with 2 Gm. of water; a characteristic very agreeable odor should be given off; now add a small crystal of potassium permanganate, when the odor of oil of bitter almonds should be developed. The aqueous solution should be rendered turbid by solution of soda, but not by ammonia-water: 1 part of the salt dissolved in 1000 parts of water should have a distinct acrid and bitter taste."—P. G.

Off. Prep.—Liquor atropiæ sulphatis, Br.

Allied Salt.—ATROPINÆ SALICYLAS, *Salicylate of atropine*, is prepared by Tichborne (1877) by dissolving 289 grains of atropine and 138 grains of salicylic acid in about 20 ounces of water, and evaporating, when 432 grains of the salt will be obtained as an uncrystallizable colloidal mass, which it is difficult to powder, and which is soluble in alcohol and in 20 parts of water at 15° C. (59° F.).

Physiological Action.—On Animals: Herbivorous animals and birds are but little affected by doses of atropine which are fatal to Carnivora; pigeons will often recover after the hypodermic injection of 2 grains of the alkaloid, and their pupils are not dilated by any dose of it. Even upon dogs the toxical action of atropine is relatively slight. The injection of 2 or 3 grains into the cellular tissue of these animals may produce a staggering gait and agitation; and the same quantity thrown into the crural vein, although it may cause rigidity and apparent death, will not necessarily destroy the animal's life. In a few hours it may appear entirely well. The action upon the several physiological systems varies with the dose of atropine. In non-poisonous doses it causes great acceleration of the heart's action with diminished vascular tension, while a general quieting effect on the cerebro-spinal system is observed. Poisonous doses seem to render morbidly acute the general and the special senses, although the perceptions do not appear to be normal, and there is no tendency to narcotism. Death, apparently, is due to exhaustion of the forces which move the heart and the respiratory organs, and is preceded by general muscular paralysis. On examination, the heart, lungs, and brain are found surcharged with blood. The experiments of Cavazzani on frogs seem to show that the action of atropine on the circulation is to weaken, and then paralyze, the heart, while it constricts the capillaries, and that either in this manner or more directly the red blood-corpuscles lose their power of absorbing oxygen (*Phila. Med. Times*, ix, 623). A vast amount of labor in experiment and great ingenuity in reasoning

have been employed to illustrate and explain the mode of action of atropine. Even if the results were uniform their rationale would be uncertain, for the most contradictory explanations of identical phenomena are proposed by different experimenters; and necessarily so, since the physiological laws upon which the phenomena depend are as far as possible from being determined. But the results of apparently identical experiments are also the reverse of constant and uniform, and hence the only purpose for which they can interest physicians is unattained. (For illustrations see *Med. Record*, xix. 255.)

The physiological antagonisms of atropine are both interesting and practically important. Those relating to opium and morphine are discussed elsewhere. (See *BELLADONNA*.) Another very important one concerns jaborandi and its alkaloid, pilocarpine. Ringer has shown experimentally that atropine antagonizes these poisons, which weaken the heart, and restores active contractions to its ventricle (*Practitioner*, xxvi. 5). His conclusions have been abundantly confirmed. It has also been demonstrated, particularly by Strauss, Luchsinger, and Vulpian, that the power of atropine to render the skin dry is due to the local action of the alkaloid, for when injected subcutaneously its influence is first exhibited immediately around the puncture. In animals or in man the dose of atropine that will arrest the sweating caused by pilocarpine is extremely small. One-millionth of a gram of atropia will have this effect in man, and in the cat one-one-hundred-thousandth of a gram is sufficient (*Lancet*, Sept. 1879). One of the most complete antagonisms is that between atropine and muscarine. It is stated by Falck as follows: "When an animal has been poisoned by muscarine, and for hours together has suffered from profuse salivation and diarrhœa, with contracted pupils, and the heart is so depressed that only a few pulsations in a minute can be detected, when respiration has almost ceased and the animal lies cold and senseless on its side, the injection of the minutest fraction of atropine will in a few minutes entirely change its condition. The pulse rises, the heart beats, the breathing revives, the discharges from mouth and bowels subside, sensibility and consciousness return, and in a little while after the atropine was used the animal, although feeble, is able to walk about" (*Samml. klin. Vorträge*, 1879). The antagonism of atropine to physostigmin is also to be noticed. The former dilates the pupil contracted by the latter.

On Man: The hypodermic injection of one-twentieth of a grain of atropine causes the pulse in 20 minutes to rise from 72 to 110, the mouth to grow dry, and the pupils to begin to dilate; the sight grows indistinct, and usually there are grotesque hallucinations, and sometimes actual delirium; there is giddiness, with an inclination to sleep, and the dryness of the mouth and throat may last for 24 hours, with more or less nervousness and instability in walking. An erythematous eruption of the skin closely resembling that of scarlatina is generally observed (*e. g.* *Med. Record*, xxiii. 457), but occasionally there is an "erythematous and pseudo-erysipelatous swelling of the face and neck" (*Times and Gaz.*, April, 1880, p. 431). The recovery of children after poisoning by this alkaloid is very remarkable. An infant nineteen months old swallowed about three-quarters of a grain of sulphate of atropine. In half an hour the skin was bright scarlet, the limbs in constant spasmodic action, with dominant rigidity, and especially rigid flexion of the thumbs and great toes. Delirium, hallucinations, drowsiness, dilated pupils existed as in other cases, but complete recovery took place in 24 hours (*Phila. Med. Times*, x. 164). Often the pulse is very rapid, the respiration is hurried at first, and then interrupted or suspended, owing sometimes to mucus obstructing the air-passages; there may be dysphagia, convulsions, retention of urine, and, after recovery, desquamation of the cuticle (*Med. Record*, xxi. 375). A feeble child of six years recovered within 24 hours after taking about half a grain of atropine, and another of half that age after as large a dose. There have been cases in which even a grain and a half of atropine has not proved fatal (*Med. News*, Dec. 1881, p. 758). An adult recovered after a dose of nine-tenths of a grain administered hypodermically (*Med. News*, May, 1881, p. 307). A case of extreme atropine-poisoning from instilling a solution of the alkaloid into the eye is recorded by Sink (*Jour. Amer. Med. Assoc.*, i. 455). On the other hand, in a case in which an excessive quantity of the alkaloid was applied to a blistered surface there were, besides the above-mentioned symptoms, including dyspnœa with dysphagia, injection of the conjunctiva and choreic movements of the limbs; the pulse grew thready, and the patient died within 2 hours. Sometimes a striking degree of cutaneous anæsthesia has been observed, and to this effect may be attributed in part the inability to direct the movements of the limbs to definite purposes, such as grasping small objects, etc. A man was found dead after taking 2 grains of atropine, and another person died from the application of an ointment of atropine to the denuded skin. The symptoms consisted of agitation,

followed by coma, a rapid and thready pulse, rigidity of the muscles, interrupted respiration, convulsions, and coma. After death by atropine the skin is usually discolored, the lungs and the right side of the heart distended with blood, the left side less so or quite empty, the brain usually congested, and the blood generally uncoagulated. The dilatation of the pupil by atropine applied to the eye has been variously explained, one view being that the medicine paralyzes the oculo-motor and excites the sympathetic and trigemini nerves. These opposite actions of the same agent at the same moment, it is true, are not very intelligible. It is apparently proved by ordinary clinical experience, as well as by physiological experiment, that the dilating action of atropine upon the pupil is a local one; but whether it is the result of combined actions upon the muscles of the iris, or of a single one which is stronger than the normal opposing force, or whether it is not due in part or chiefly to the power of the agent to contract the blood-vessels which supply the iris, are questions which are not, perhaps, conclusively settled. (Further details upon the action of atropine will be found under the head of *BELLADONNA*.) Homatropine and atropine have been compared relatively to their mydriatic properties by Galizowski, Berteau, and others, and also by Schell, Oliver, Risley, and Schaeffer, who confirmed previous results and showed that the former agent is identical with the latter in the nature of its action upon the eye, but that its effects are less complete and durable. The transient influence of homatropine renders it more eligible for the examination of the chambers of the eye (*Amer. Jour. of Med. Sci.*, July, 1881, p. 150; *Phila. Med. Times*, xi. 7; *Archives of Ophthalmology*, x. 196).

Medical Uses.—For the relief of *pain* atropine is, next to opium, of the highest value, and especially for two of its severest forms, the pain of *neuralgia* and the pain of *spasm*. It should be employed in both hypodermically. Sciatica is the most unyielding, and intercostal neuralgia the most amenable, to this medicine. Neuralgia of the trigemini holds in this respect a middle position. In sciatica the dose must be large. One-sixteenth of a grain has been used with curative effect. For the pain of *cancer*, and other local pains of analogous origin, a solution of 1 part of atropine in 1000 of water has been applied with great advantage on compresses covered with oiled silk or sheet rubber (Auger). A 1 per cent. solution instilled into the ear is one of the most efficient remedies for *otache*, especially when due to inflammation of the middle ear. Spasm itself, as it occurs in *tetanus* and in *poisoning by strychnia*, has been successfully combated by the hypodermic use of atropine. In such cases the dose must be large, being not less than one-twentieth of a grain repeated at intervals of not more than an hour until its characteristic effects are developed. In a case of traumatic *tetanus* the dose, varying from $\frac{1}{60}$ to $\frac{1}{40}$ of a grain, was given from two to four times a day for 11 days, when convalescence was established. The usual physiological effects of the drug were not developed (*Practitioner*, xxiii. 209). As more convenient for administration than belladonna, atropine may be used in the treatment of *whooping cough*, in the dose of $\frac{1}{120}$ grain once a day or oftener, and avoiding the production of its physiological effects. Various other forms of spasm are more or less subject to the power of this medicine. They will be found more fully described in connection with *BELLADONNA*, but it may be stated that almost every spasmodic affection may be influenced by that medicine or by atropine. It may be mentioned here, however, that sulphate of atropine administered hypodermically in the dose of from $\frac{1}{60}$ to $\frac{1}{30}$ of a grain has prevented the full development of the *epileptic* paroxysm and lessened the frequency of its occurrence. Indeed, it has been claimed to be more certain in its results, and attended with less inconvenience to the patients, than bromide of potassium (Weiss, *Centrbl. f. Therapie*, i. 268). In the following spasmodic disorders it may also be employed: spasm of the *anus*, the *urethra*, the *bladder*, the *ureter*, the *uterus*, the *vagina*, the *rectum*, the *large and small intestine*, the *biliary ducts*, the *bronchia*, the *larynx*, the *oesophagus*, etc. In all of these affections the hypodermic injection of atropine may be substituted for the use of any preparation of belladonna, internal or local. In the very opposite condition which occurs in poisoning by *Catubar bean* it has been proved that atropine is a true antidote in nearly the whole range of its action. But atropine counteracts or prevents the lethal action of physostigma when given in doses which are far below the minimum fatal doses of the former. Sulphate of atropine should be injected subcutaneously in doses of from $\frac{1}{30}$ to $\frac{1}{60}$ of a grain, and repeated until the pupils become dilated, the pulse-rate increased, and the secretion of bronchial mucus is checked. The therapeutical antagonism of belladonna and atropine to opium and morphine is confirmed by many cases of *opium-poisoning* treated by the hypodermic injection of atropine. Johnson of Shanghai is said to have used this treatment successfully in upward of three hundred cases (*Practitioner*, xxvi.

138). The hypodermic dose of atropine and the frequency of its repetition have varied in different cases between remote extremes. In one, for example, five doses, each of $\frac{1}{12}$ grain, were given within as many hours, and the case was of a desperate character, but ended in recovery (*Med. News*, xl, 318). In another instance with a like termination $\frac{1}{10}$ grain of atropine was injected, and afterward $\frac{1}{2}$ grain (*Practitioner*, xxiii, 123). It is evident that the dose must be determined by the exigencies of each case. It has been proposed to use atropine as a physiological antidote to *chloroform* by administering a hypodermic injection of $\frac{1}{120}$ to $\frac{1}{60}$ grain of atropine with $\frac{1}{2}$ or $\frac{1}{12}$ grain of a morphine salt before the inhalation of the anæsthetic is commenced (Fraser). The effects of *heat-exhaustion* (one of the forms of sunstroke) have been treated with alleged success by the hypodermic injection of atropine, strengthening the heart, stimulating the brain, restoring consciousness, and preserving life.

In various diseases of the eye the use of atropine is peculiarly appropriate; it is now universally employed for dilating the *pupil* so as to permit the inspection of the parts behind the iris and to facilitate the operation for *cataract*, but, owing to its more transient action, homatropine is to be preferred for this purpose, and also because it is less irritating than atropine. In inflammations of the cornea and of the iris it diminishes the congestion of the eye, and thereby lessens the pain and photophobia, and favors the healing of ulcers in the former tissue; and when *prolapse* of the *iris* takes place through a corneal ulcer, or when adhesion occurs between the two, the action of atropine, by contracting the iris toward its periphery, tends to prevent permanent deformity of the organ and impairment of the sight. *Myopia*, or short-sightedness, being often produced by an excessive strain of the eyes through spasm of accommodation, may sometimes be prevented from reaching its full development by resting the organs and maintaining for several weeks a paralysis of accommodation by means of atropine. By a similar method it is claimed that a number of cases of *strabismus* in its early stage have been cured (*Philæ. Med. Times*, xi, 144). Atropine should never be used in *glaucoma*. It is probably through the power involved in these operations that atropine has been found efficient in cases of *profuse sweating* and also of *diarrhœa* and *galactorrhœa*. The power of sulphate of atropine to control the *night-sweats* of *phthisis* and other debilitating diseases is well established. About $\frac{1}{100}$ grain hypodermically is the average commencing dose required. The condition of the patient in other respects need not influence the use of the medicine—not even the fact of perspiration having already commenced. Sometimes existing profuse perspiration is checked by the medicine within a few minutes. Its effects may also extend over several nights, but occasionally they are not immediate, but are developed at the end of 24 hours or more. It is not essential to give the injection at bed-time. It may be administered hypodermically, or by the mouth in camphor-water, or in pill. In the latter way the commencing dose should be about $\frac{1}{15}$ grain (*Practitioner*, xxiii, 93). Homatropine, used for the same purpose, is decidedly inferior not only to atropine, but also to “Dover’s powder, picrotoxin, and other means” (Murrell). Atropine has been found useful in serous *diarrhœa*; in the *salivation* of the insane; in the forming stage of *coryza*, when given in very minute doses (*Boston Med. and Surg. Jour.*, Aug. 1883, p. 151); and in *incontinence of urine* and *æsophagism* (Girard, *Bull. de thérap.*, xcviii, 481). In *spermatorrhœa*, due to atony and morbid irritability of the genital system, erections may be produced by the use of atropine and the passive seminal discharges arrested. This alkaloid, used along with morphine in hypodermic injections, tends to prevent the nausea and vomiting which are apt to be caused by morphine alone. *Menorrhagia* has been controlled by injecting hypodermically $\frac{1}{200}$ grain of atropine twice a day (Tacke). *Urticaria* has been cured, temporarily at least, by means of $\frac{1}{15}$ grain of sulphate of atropine taken twice a day (Schwimmer). Atropine is a physiological antidote to *jaborandi* and *pilocarpine*, promptly arresting the profuse sweating induced by those articles. The antagonism of atropine and *prussic acid* has been both maintained and denied; but even if it were real in a physiological sense, it would practically be of little importance, since the rapid action of a lethal dose of prussic acid cannot be overtaken by the slower operation of atropine.

Administration.—Except where otherwise stated, a solution of atropine used for any of the above purposes, including hypodermic injection, should not exceed the strength of 1 part in 100 of water. It may be applied to the eye by means of a fine camel’s-hair brush while the lower punctum lachrymale is compressed to prevent the passage of the solution into the nasal passages and its consequent absorption. Several cases of atropine-poisoning have arisen in this manner. Klein recommends a mixture of 1 part of sulphate of atropine to 200 parts of vaseline as preferable to a solution. Thin gelatin

disks, imbued with a solution of the salt, 1 : 100, are sometimes inserted between the lower lid and the eyeball, in order to prevent the accident just alluded to. A solution of homatropine hydrobromate containing 16 grains to the fluidounce of distilled water is convenient for ophthalmological purposes. An ointment of atropine may be used containing 1 grain of the alkaloid to a drachm of lard (Gm. 0.06 to Gm. 4.00).

AURANTII AMARI CORTEX, U. S.—BITTER ORANGE-PEEL.

Aurantii cortex, Br.; *Cortex fructus aurantii*, P. G.; *Cortex aurantiorum*, *Cortex pomorum aurantii*.—*Écorce (zestes) d'orange amère*, *Écorce de bigarade*, Fr.; *Pomeranzenschale*, G.

The rind of the fruit described below.

AURANTII FRUCTUS, Br. Add.—BITTER ORANGE.

Poma aurantiorum, *Aurantia*.—*Serville Orange*, E.; *Orange amère*, *Bigarade*, Fr.; *Pomeranzen*, G.

The ripe fruit of *Citrus vulgaris*, *Risso*, s. *C. Aurantium*, var. *amara*, *Liné*, s. *C. Bigaradia*, *Duhamel*. Bentley and Trimen, *Med. Plants*, 50.

Nat. Ord.—Aurantiaceæ.

Origin.—The bigarade orange is a small tree which is indigenous to the northern portion of India, but is largely cultivated near the Mediterranean, and in some of the West India Islands, and in that part of the United States which borders on the Gulf of Mexico. It closely resembles the sweet orange, excepting in the fruit, leaves, and flowers, the latter being more fragrant.

Description.—1. **THE FRUIT.** The unripe fruit falling from the tree is collected and extensively used on the continent of Europe, where it is known as orange-berries (E.), *orangettes* or *petits grains* (Fr.), *Unreife Pomeranzen* (G.), and is official as *Fructus*

FIG. 35.

Citrus vulgaris, *Risso*.

FIG. 36.

Orange-peel: transverse section: mag. 65 diam.

(*Baccæ*) *aurantii immaturi* vel *Aurantia immatura*, P. G. They are globular or ovate-globose, $\frac{1}{8}$ to $\frac{3}{8}$ inch (3–15 Mm.) in diameter, with a circular depressed scar at the base surrounded by eight to twelve smaller depressions, and with a slightly projecting remnant of the style at the apex. They are greenish to brownish-black in color, densely rugose, and consist of eight to ten or twelve cells having a central placenta, and two rows of ovules in each cell. Their odor is agreeably aromatic, their taste aromatic and bitter, the aromatic properties being due to a volatile oil which is contained in large oil-cells situated in the pericarp near the epidermis.

The ripe fruit is of the size and shape of a sweet orange, but is rougher externally, and of a reddish-orange color, the spongy parenchyma underneath being white, and the

juice having an acid and bitter taste. It has been made officinal in the British Pharmacopœia for the purpose of preparing the *Tinctura aurantii recentis*.

2. **THE PEEL.** Orange-peel is dried in narrow, thin bands or in quarters, the epidermis being glandular and of a dark brownish-green color; it has a fragrant odor and an aromatic, bitter taste. It should have very little of the spongy, white inner layer adhering to it. In commerce it is usually found in flat or curved elliptical pieces, about 3 inches (37 Mm.) long and $\frac{1}{2}$ inch (3 Mm.) or more in thickness, the surface being of an uneven somewhat glandular appearance, covering the numerous large oil-cells and the spongy white parenchyma. This latter is directed to be removed by most pharmacopœias, only the yellowish rind (*flavedo aurantii*) being used. The Curaçoa orange-peel is obtained from a variety of the bitter orange cultivated in the island of Curaçoa. It is scarcely half the thickness of the ordinary orange-peel, and externally of a dark-greenish color. The commercial article sold under this name frequently consists merely of thin slices or spiral bands cut from the fully-developed but still unripe fruit grown elsewhere. The white parenchyma is colored yellow by alkalies and black by ferric salts.

3. **THE LEAVES**, *Folia aurantii*, are smooth, ovate, or ovate-oblong, entire or slightly crenate on the margin, pellucid-punctate, aromatic, and have a jointed petiole, with a broadly obovate or obovate wing.

Constituents.—The white parenchyma of orange- and lemon-peel, but more particularly the unripe bitter orange, contains a crystalline bitter principle which was named *hesperidin* by Lebreton, its discoverer (1828). Hilger (1876) obtained from 5 to 8 per cent. of it from orange-berries by exhausting them first with water, afterward with diluted alcohol containing 1 per cent. of potassa, and precipitating the tincture with hydrochloric acid. Crude hesperidin is purified by Ed. Hoffman (1876) by recrystallization from hot alcohol, when it is obtained in white needles requiring about 5000 parts of hot water for solution; it is insoluble in ether, benzol, fats, and volatile oils, but is readily soluble in alcohol and hot acetic acid; its solutions in alkalies become yellow and orange-colored; the potassa solution, evaporated and the residue warmed with dilute sulphuric acid, shows a red and violet color. Hesperidin, $(C_{22}H_{36}O_{12})$, melts at 245° C. (473° F.), becomes browned (dingy blackish-brown on warming, Flückiger) with ferric chloride, and by dilute acids is split into glucose and *hesperetin*, which melts at 223° C. (433.4° F.) and is soluble in alcohol and ether. Orange-peel also contains gum, albumen, some fixed oil, resin, volatile oil (see *OLEUM AURANTII CORTICIS*), and a principle resembling tannin in its behavior to iron salts.

The volatile oil obtained by the distillation of orange-berries with water was formerly known as *essence de petit grain*, but much of that which is now found in commerce is obtained from the leaves and young shoots. In chemical composition it resembles the oil of orange, but differs from it in odor, which varies even to some extent in the different cultivated varieties of the bitter orange.

Pharmaceutical Preparations.—*ELIXIR AURANTIORUM COMPOSITUM*, s. *Elix. viscerale Hoffmanni*, *P. G.* Macerate for 8 days bitter orange-peel 50 parts, cinnamon 10 parts, and potassium carbonate 2.5 parts in sherry wine 250 parts; express, and dissolve in the liquid 5 parts each of the extracts of gentian, wormwood, buckbean, and cascarrilla; set aside and filter.

ELIXIR AMARUM, *P. G.*, Bitter Elixir. Dissolve extract of absinth 2 parts and oil sugar of peppermint 1 part in water 5 parts, and add bitter tincture and aromatic tincture of each 1 part.

TINCTURA AMARA, *P. G.*, Bitter tincture. Digest for a week centaury, gentian, of each 3 parts, bitter orange-peel 2 parts, orange-berries and zedoary of each 1 part, in alcohol (spec. gr. .894) 50 parts; express and filter.

Off. Prep.—*Of the fruit*: *Tinct. aurantii recentis*, *Br.* *Of the peel*: *Extract. aurant. amari fluid.*, *U. S.*; *Infusum aurantii*, *Infus. aurantii comp.*, *Infus. gentianæ comp.*, *Mistura gentianæ*, *Spiritus armoraciæ comp.*, *Br.*; *Tinct. aurantii amari*, *Tinct. cinchonæ comp.*, *Tinct. gentianæ comp.*, *U. S.*, *Br.*

Medical Uses.—The simple and compound infusions of orange-peel (*Br.*) are used as vehicles for other medicines and to allay *indigestion*, *flatulence*, and *colic*. They may be taken in doses of 1 or 2 fluidounces (Gm. 32–64).

AURANTII DULCIS CORTEX, *U. S.*—SWEET ORANGE-PEEL.

Cortex aurantiorum dulcium.—*Écorce (zestes) d'orange douce*, *Fr.*; *Apfelsinenschalen*, *G.*

The rind of the fruit of *Citrus Aurantium*, *Risso*, s. *Cit. dulcis*, *Link.* Woodville, *Med. Bot.*, 188; *Risso*, *Hist. Orang.*, 3, 39; Bentley and Trimen, *Med. Plants*. 51.

Nat. Ord.—Aurantiaceæ.

Origin.—This variety of the orange tree, known as the sweet or Portugal orange, is extensively cultivated in warm countries; it differs from the preceding in the leaves having the petioles more narrowly winged, and in the fruit having an agreeable sweetish acidulous taste; many varieties have been produced by cultivation.

Description.—Sweet orange-peel agrees in structure and in most of its physical properties with bitter orange-peel; it is, however, always of a lighter and more yellow color, of an agreeable sweetish aromatic odor, and of a slightly bitter taste. Its composition is the same as that of the bigarade orange, except the bitter principle, which is present in much smaller proportion. (See also OLEUM AURANTII CORTICIS.)

Pharmaceutical Preparations.—CONFECTIO AURANTII CORTICIS, *U. S.* 1870; Conserva aurantii.—Confection of orange-peel, *E.*; Conserve d'écorce d'orange, *Fr.*; Apfelsinenschalen-conserven, *G.*—Take of sweet orange-peel, recently separated from the fruit by grating, 1 part, and beat it with sugar 3 parts, gradually added, until they are thoroughly mixed.—*U. S.* 1870.

Off. Prep.—Syrup. aurantii, Tinct. aurantii dulcis, *U. S.*

Physiological Action and Uses.—Orange-peel is a mild stimulant of digestion, because it contains an essential oil which, in the fresh bitter orange, is endowed with very active irritant properties and acts upon the nervous system, in small doses stimulating it, but in large doses or by continued use depressing and deranging all the nervous functions. Dried orange-peel and its preparations are employed along with pure bitters to render them stimulant and more acceptable to the stomach, as well as to improve their taste. They are also associated with purgatives which tend to *gripe* and when the bowels are *flatulent*. Orange-peel is prescribed as an addition to many infusions and decoctions. It should not be added to the latter until ebullition has terminated. The confection of orange-peel (*Pharm.* 1870) may be used for disguising the taste and qualifying the acid action of various medicinal powders, especially those of the cathartic class.

AURANTII FLORES, *U. S.*—ORANGE-FLOWERS.

Flores naphæ.—Fleurs d'orange, *Fr.*; Orangenblüthen, Pomeranzenblüthen, *G.*

The partly-expanded flowers of *Citrus Aurantium* and of *C. vulgaris*, *Risso*.

Origin.—See AURANTII FRUCTUS.

Description.—The flowers grow singly in the axils of the upper leaves, and consist of a small cup-shaped five-toothed calyx, and of five oblong, obtuse, fleshy, and glandular punctate petals, which are white, or in the dried state pale brownish-white, and about $\frac{1}{2}$ inch (12 Mm.) long. The numerous (about twenty) stamens are united by the lower part of their filaments into three or more bundles. The globular ovary rises from a small fleshy disk, and bears a cylindrical style with a globular stigma. Orange-flowers have a highly fragrant odor, the bitter variety being more aromatic than the sweet; their taste is aromatic and bitterish.

When it is desired to keep fresh orange-flowers for some time, they may be preserved by mixing them well with half their weight of chloride of sodium, pressing the mixture in a suitable jar and keeping it, well closed, in a cool place.—*U. S.*

Lemon-flowers are externally of a reddish color and have a different odor.

Constituents.—Boullay found (1828) in orange-flowers, besides the volatile oil (see OLEUM AURANTII FLORUM), gum, bitter extractive, acetic acid, and salts. The bitter taste is probably due to the presence of hesperidin. (See AURANTII AMARI CORTEX.)

Off. Prep.—Aqua aurantii florum, *U. S.*

Medical Action and Uses.—Orange-flowers are chiefly used to prepare a distilled water which is an agreeable vehicle for some medicines, and is believed to stimulate the nervous system slightly, allaying its superficial disorders in very susceptible persons.

AURI ET SODII CHLORIDUM, *U. S.*—CHLORIDE OF GOLD AND SODIUM.

Auro-natrium chloratum, *P. G.*; *Chloruretum aurico-sodicum*.—Chloraurate de sodium, Chlorure d'or et de sodium, *Fr.*; Natriumgoldchlorid, *G.*

A mixture composed of equal parts of dry chloride of gold [AuCl_3 ; 302.4. — AuCl_3 ; 302.4] and chloride of sodium [NaCl ; 58.4. — NaCl ; 58.4].

Preparation.—Dissolve with the aid of a gentle heat pure gold 65 parts in a mixture composed of nitric acid 65 parts and hydrochloric acid 240 parts; dilute the solution with water 200 parts, add pure dry sodium chloride 100 parts, and evaporate in a water-bath and with constant stirring to dryness. Result, 200 parts.—*P. G.*

This is an improvement on the process of the former German Pharmacopœia, according to which the gold solution was evaporated nearly to dryness before it was mixed with the sodium chloride. Constant stirring is necessary during the final evaporation, in order to secure a uniform mixture, which persistently retains from 6 to 7 per cent. of water.

Properties.—This preparation is "an orange-yellow powder slightly deliquescent in damp air, odorless, having a saline and metallic taste and a slightly acid reaction. The compound is very soluble in water; at least one-half of it should be dissolved by cold alcohol. When exposed to a red heat it is decomposed and metallic gold is separated. A fragment of the compound imparts an intense, persistent yellow color to a non-luminous flame. Its aqueous solution yields, with test solution of nitrate of silver, a white precipitate insoluble in nitric acid, but soluble in ammonia."—*U. S.*

The French Codex orders the crystallized double salt, $\text{NaCl} \cdot \text{AuCl}_3 \cdot 2\text{H}_2\text{O}$ (mol. weight 396.8), to be prepared by dissolving the auric chloride prepared from 10 parts of gold in sufficient distilled water, adding 3 parts of chloride of sodium and evaporating to crystallization. It forms orange-colored rhombic prisms or plates which are soluble in water and alcohol, not deliquescent, fusible, and at a red heat are gradually decomposed, 49.4 per cent. of metallic gold being separated. It is known in France as *sel de Chrestien* and *sel de Figuier*.

Tests.—"On bringing a glass rod dipped into water of ammonia close to a portion of the compound no white fumes should make their appearance (absence of free acid). If 0.5 Gm. of chloride of gold and sodium be dissolved in 20 Ccm. of water, and treated with a clear solution of 2 Gm. of ferrous sulphate in 20 Ccm. of water acidulated with a few drops of sulphuric acid, a brown precipitate of metallic gold will be thrown down. If after at least 2 hours this precipitate be separated, well washed, dried, and ignited, the residue of metallic gold should weigh not less than 0.162 Gm. (corresponding to 32.4 per cent. of metallic gold)."—*U. S.* If .5 Gm. of it be slowly heated to redness and afterward washed with water, the residue after drying should weigh not less than .150 Gm., corresponding to 30 per cent. of gold.—*P. G.* This test corresponds to 46.27 per cent. of AuCl_3 and to 60.67 per cent. of $\text{NaCl} \cdot \text{AuCl}_3 \cdot 2\text{H}_2\text{O}$. The gold test of the U. S. P. corresponds to 49.94 and 65.53 per cent. respectively.

AURUM.—GOLD.

Or, Fr.; Gold, G.

Symbol Au. Atomicity univalent and trivalent. Atomic weight 196.2.

Origin and Properties.—This well-known metal is chiefly found in the metallic state, always associated with other metals and frequently in various native sulphurets. It is the most ductile of all metals, softer than silver, fuses at nearly 1200°C . (2200°F .), has the density 19.3, and is of a reddish-yellow color and metallic lustre, but when powdered of a brown color, acquiring lustre by pressure. It is not altered by exposure to air and water, and does not dissolve in acids, but is soluble in liquids containing or generating chlorine. The following preparations of gold have been used:

AURUM FOLIATUM, *gold-leaf*, is used for coating pills; is transparent, with blue or green color; it should not be attacked by nitric acid nor become tarnished by ammonia.

AURI PULVIS, *powdered gold*, may be prepared by triturating gold-leaf with crystals of milk-sugar, potassium sulphate, or other hard soluble substance, until the metallic lustre has completely disappeared, when the compound is washed out with water. A solution of chloride of gold yields the metal in a finely-divided condition when added to solution of ferrous sulphate, oxalic acid, or other oxidizable compound.

AURI CHLORIDUM, *chloride of gold* or *auric chloride*, AuCl_3 . On dissolving pure gold in nitro-muriatic acid and crystallizing, yellow *hydrogen-gold chloride*, $\text{AuHCl}_4 \cdot 4\text{H}_2\text{O}$, is obtained, which in a dry atmosphere loses $1\text{H}_2\text{O}$ (Julius Thomsen, 1878, 1883). But on evaporating the solution to dryness, dissolving in water, filtering from some aurous chloride, AuCl , and again evaporating, auric chloride is obtained as a dark-red or red-brown salt. It is decomposed above 150°C . (302°F .), dissolves readily in water, and is also soluble in alcohol, ether, and volatile oils, which solutions are gradually reduced. Its solution yields with stannous chloride a dark-brown or purple precipitate known as

purple of Cassius, the exact composition of which is still unknown. J. A. Koenig (1882) ascertained that an aqueous solution of gold chloride in contact with charcoal previously deprived of all foreign constituents is slowly reduced to metallic gold, hydrochloric acid and carbonic acid gas being formed at the same time.

AURI ET AMMONII CHLORIDUM, *ammonio-chloride of gold*. Equal parts of auric chloride and chloride of ammonium are dissolved in water, acidulated with hydrochloric acid, and the solution evaporated to dryness (Dorvault). It resembles the preceding.

AURI CYANIDUM, *cyanide of gold*, is best prepared, according to Figuier (1847), by dissolving pure auric chloride in water, and adding a solution of an equivalent weight of pure potassium cyanide, when a lemon-yellow precipitate will be obtained; a larger quantity of the latter solution would change the color to brownish- or orange-yellow. It is inodorous and tasteless, and contains 75 per cent. of gold. With an excess of cyanide of potassium, used in a concentrated hot solution, *auro-potassium cyanide*, containing 55 per cent. of gold, is obtained in colorless tabular crystals, which on exposure become white from loss of water of crystallization.

AURI IODIDUM, *iodide of gold*, AuI_3 , is obtained by precipitating a solution of auric chloride with potassium iodide, avoiding an excess of the latter, washing with water, and drying carefully. It is a dark-green powder, which is soluble in solution of potassium iodide, and on exposure loses iodine, being first converted into yellow *aurous iodide*, AuI , and finally into metallic gold.

AURI OXIDUM, *auric acid, hydrate (oxide) of gold*, AuH_3O_3 . Pelletier directs the boiling of a solution of auric chloride with an excess of magnesia or oxide of zinc, collecting the precipitate upon a filter, and washing it first with dilute nitric acid (which must be free from chlorine), and afterward with water. Frémy (1850) adds to auric chloride sufficient solution of potassa until the precipitate is redissolved, the solution is boiled for 15 minutes, or until its dark-brown color has changed to light-yellow, when it is acidulated with sulphuric acid and the precipitate washed and dried; it retains a trace of potassium. Hydrate of gold is a blackish-brown powder which is readily soluble in hydrochloric and hydrobromic acids, and when heated to 245°C . (473°F .) or boiled with alcohol yields metallic gold.

Physiological Action.—The action of gold has, to some extent, an analogy with that of mercury, its salts producing local effects varying between irritation and causticity, and internally developing a state of erethism which resembles strongly mercurial fever. Within this limit it is represented as stimulating the functions generally, and in man especially the genital activity, while in women it is said to augment the menstrual flux. Some of the most detailed and minute descriptions of its effects are drawn from the poetical observations of Italian physicians (Gozzi).

Medical Uses.—It appears that gold compounds, when persistently employed, may, through the febrile erethism above referred to, tend to eliminate the *syphilitic* poison from the system and arouse the sluggish vital forces as they exist in *scrofula*. Indeed, it is said that this action sometimes goes so far as to give a destructive energy to the morbid process. It is unnecessary to enter into much detail respecting a medicine which has deservedly fallen into disuse, and whose merits give it no present claim to a rehabilitation. It has, however, been used with apparent advantage by Martineau in a case of inveterate syphilis, thus: Water (Gm. 1000: chloride of gold and chloride of sodium, of each 1 Gm. 1 to 3 teaspoonfuls daily (*Bull. et Mém. Soc. de thérap.*, 1883, p. 52). Powdered gold or its oxide is applied by friction upon the sides of the tongue in the dose of from $\frac{1}{3}$ grain to 3 or 4 grains (Gm. 0.01–0.20) daily. The oxide is given internally in pill, and in the dose of $\frac{1}{10}$ grain (Gm. 0.006), after meals, and gradually augmented. Chloride of gold and sodium is a caustic, but in a diluted condition may be applied to the interior of the mouth, as above mentioned. The salivation which follows this manœuvre is due to a local and not to a constitutional action of the metal. The dose of this preparation is about $\frac{1}{20}$ grain (Gm. 0.003). Chloride of gold is a caustic resembling in its action nitrate of silver. It has been applied to *lupoid*, *cancerous*, and other *ulcers*.

AVENÆ FARINA, U. S. 1870.—OATMEAL.

Farine d'avoine, Fr.; *Hafermehl*, G.

The meal prepared from the seed of *Avena sativa*. *Linné*. Bentley and Trimen. *Med. Pl.*, 292.

Nat. Ord.—Graminacæ.

Origin.—The native country of oat has not been ascertained, though it is supposed

to have originated from one of the wild species indigenous to Europe. It is cultivated in most civilized countries, even in the subarctic regions, and many varieties or species are known, all having a loose panicle and two- or occasionally three-flowered spikelets. The kinds more rarely found in cultivation, except in certain localities, are *A. orientalis*, *Schreber*, *A. strigosa*, *Schreber*, *A. nuda*, *Liné*, and *A. brevis*, *Roth*. The fruit is closely invested by the paleæ, lanceolate, pointed, and grooved on the inner side. Oats deprived of the paleæ or husk are called *groats*. By grinding the grains oatmeal is obtained.

Description.—Oatmeal is a grayish-white not uniform powder, in which fragments of the tissue are observed by the naked eye; it has a slight odor and a somewhat bitterish taste. Viewed under the microscope, the starch consists of medium-sized polyhedral or muller-shaped granules, with a rather distinct hilum, but without observable laminæ. Frequently two or three are united, or even a larger number, forming a nearly spherical mass with a checkered surface, and readily separating by pressure into the separate granules.

Constituents.—Oats consist on an average of 25 per cent. of husks and 75 per cent. of grain; the former contain 1 to 1½ per cent. of fixed oil, ½ to ¾ per cent. of sugar and gum, nearly 2 per cent. of protein compounds, and 6½ to 7 per cent. of ash, the remainder being cellulose. The grain contains 64½ to 66 per cent. of starch, 5 to 7 of fat, 18 to 21 per cent. of protein compounds, 1 to 3 per cent. of salts, the remainder being sugar, gum, and cellulose. The largest portion of the protein compounds is *avenin*, which may be obtained from oatmeal by treating it in the cold with a weak solution of potassa, decanting from the sediment, and precipitating by acetic acid; the impure *avenin* is washed with diluted and strong alcohol and ether, redissolved in weak potassa solution, and precipitated by acetic acid (Kreusler, 1869). *Avenin* closely resembles legumin in its behavior to solvents; it contains 17 per cent. of nitrogen and ¾ to 1 per cent. of oxygen.

Medical Action and Uses.—Oatmeal is an excellent article of food, but is apt to undergo fermentation in the stomach, producing flatulence and sour eructations. It is more nutritious than purely starchy articles, such as arrow-root and sago; and, being somewhat laxative, in consequence partly of its usually containing a portion of bran, it forms an appropriate article of diet in cases of habitual *constipation* and inertia of the intestines. The insoluble bran is, however, prone to accumulate, and sometimes forms concretions. Oatmeal gruel is prepared by slowly boiling from 1 to 2 ounces (Gr. 32–64) of oatmeal with 3 pints of water until reduced to 2 pints, straining the decoction, allowing it to stand until cool, and then rejecting the supernatant liquid. Its flavor may be improved by the addition of raisins toward the end of the boiling, and also by means of sugar and nutmeg. It has recently been claimed that an alcoholic tincture of oats has been used successfully in overcoming the *opium habit*, but without proof that any active element of oats is soluble in alcohol or any sufficient clinical evidence of the alleged virtues of the preparation.

AZEDARACH, U. S.—AZEDARACH.

Pride of India, *Pride of China*, E.: *Écorce d'azedarach*, *Écorce de margousier*, Fr.; *Zedrachrinde*, G.

The bark of the root of *Melia Azedarach*, *Liné*.

Nat. Ord.—Meliaceæ.

Origin.—Azedarach is a handsome tree which is indigenous to China and India, and cultivated as an ornamental tree in Southern Europe and in the United States from Virginia southward; in the Gulf States it has been completely naturalized. It grows rapidly to the height of 30 or 40 feet (9 to 12 M.), has large deciduous and glabrous bipinnate leaves, the leaflets being lance-ovate, acuminate, and serrate, and bears panicles of lilac-colored fragrant flowers and yellowish globular drupes of the size of a cherry, which by fermentation yield considerable alcohol. In the East Indies the bark of the *nim tree* or *margosa*, *Melia Azadirachta*, *Liné* (*Azadirachta indica*, *Jussieu*), is used as a tonic and febrifuge; the simply pinnate leaves are employed as a local stimulant, and a fixed oil which is expressed from the fruit has a strongly bitter taste and is employed as an anthelmintic, and externally in rheumatic complaints.—Bentley and Trimen, *Med. Plants*, 62.

Description.—The bark is met with in irregular curved pieces and quills, 1 or a few

FIG. 37.

Oat Starch, magnified 250 diameters.

inches long and $\frac{1}{4}$ inch (6 Mm.) or more in diameter. The first layer of corky tissue is thin, of a blackish-brown color, somewhat glossy, and forms irregular longitudinal ridges or patches upon the bright red-brown cork underneath. In older barks the corky layer is rust-brown and two or three times thicker than the remaining portion of the white inner bark, which contains a few scattered pale-yellow bast-fibres and is tangentially striate. The inner surface is whitish or pale-brownish, uneven, and longitudinally striate. The bark breaks with a short and smooth, and in the inner portion more or less fibrous, fracture. The cork has very little taste, but the inner bark is at first sweetish, afterward bitter and nauseous. It should be collected from the smaller roots or deprived of the thick rust-brown nearly tasteless corky layer. It yields its virtues to hot water and diluted alcohol.

Constituents.—The bitter principle was isolated by Jacobs (1879) in the form of a yellowish-white resin which is almost insoluble in water, oil of turpentine, and petroleum benzin, slightly soluble in carbon bisulphide, and freely soluble in alcohol, ether, and chloroform. The inner bark contains no tannin. Its constituents may be analogous to those of *nim-bark*, in which Broughton (1873) found a bitter, dark-brown resin-like principle, $C_{36}H_{50}O_{11}$, which is slightly soluble in water, but dissolves in alcohol, benzol, carbon bisulphide, and ether. Another amorphous principle, more soluble in water, and a crystalline fatty substance, were likewise obtained. Cornish (1856) had separated a bitter crystalline principle, *margosin*, besides volatile oil, resin, and other widely-diffused constituents.

Allied Plants.—The bark and other parts of different species of *Guarea* and *Moschoxylon*, indigenous to the West Indies and tropical America, possess the odor of musk. The bark of several species of *Trichilia*, met with in India, Africa, and South America, is purgative and emetic. *Carapa guianensis*, *Abulei*, and *Car. Touloucouna*, *Guillemin et Perrottet*, yield anthelmintic bark and a bitter fixed oil, known as *crab oil*, *kundah*, or *callicoumah oil*, the latter being expressed from the seeds. *Swietenia Mahagoni*, *Linne*, indigenous to the West Indies and tropical America, particularly Mexico, yields the well-known *mahogany-wood*, and a similar wood is obtained in Western Africa from *Khaya senegalensis*, *Guillemin et Perrottet*; both species have a bitter and strongly astringent bark. *Cedrela odorata*, *Linne*, is the *Jamaica red cedar*; all parts of it are bitter and unpleasantly odorous, but old wood is fragrant. *Soymdia* (*Swietenia*, *Willdenow*) *febrifuga*, *Jussieu*, yields the East Indian *robin-bark*, a useful astringent tonic. *Mahogany-wood* contains *catechin*, according to Cazeneuve and Latour (1875).

Physiological Action and Medical Uses.—Even from the period of Arabian medicine the poisonous properties of azedarach have been known, and then, as now, it was stated to have produced faintness, giddiness, dimness of sight, mental confusion and vomiting; later observers have added to these symptoms stertorous breathing, stupor, dilatation of the pupils, cold sweat, and purging. All of these effects resemble those produced by *spigelia*. The active properties appear to reside in the bark of the root. The berries are often eaten without injury by children and also by birds. Cows and horses are not injured by the leaves. Indeed, the latter are said to be given to horses infested with “bots,” and the berries have been found an attractive and nutritious food for horses. In India and the southern portions of the United States azedarach-bark is said to be the most popular *vermifuge* for lumbricoid ascarides. It is usually administered in a decoction made by boiling 2 ounces (Gm. 64) of the bark (fresh, if possible) in a pint of water until reduced one-half. For a child the dose is a tablespoonful every 2 or 3 hours until it affects the stomach and bowels. It should be followed by a cathartic.

BALSAMUM PERUVIANUM, U. S., Br., P. G.—BALSAM OF PERU.

Balsamum peruvianum nigrum, *Balsamum indicum*.—Baume de Pérou, Baume des Indes, Fr.; *Perubalsam*, G.

A balsam obtained from *Myroxylon* (*Myrospermum*, *Royle*, *Toluifera*, *Baillon*) *Pereiræ*, *Klotzsch*. Bentley and Trimen, *Med. Plants*, 83.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—Balsam of Peru was for a long time supposed to be derived from *Myroxylon peruiferum*, *Linne filius*, a tree growing in Brazil and near the west coast of South America. Pereira (1850) showed that the drug produced in the state of San Salvador in Central America comes from an apparently different species, which he provisionally distinguished as *Myrospermum Sonsonate*. Carson regarded the two species as identical, but, according to Royle, Klotzsch, and others, they are specifically distinct. (See *Am. Jour.*

Pharm., 1860, pp. 296 and 411; 1864, p. 145.) The plant in question is a tree attaining a height of about 50 feet (15 M.), and branching from 7 to 10 feet (2 to 3 M.) above ground. It has imparipinnate leaves with the leaflets oval-lanceolate, somewhat attenuate above, and slightly emarginate, the flowers in subaxillary racemes, and oblan-ceolate indehiscent one-seeded legumes about 4 inches (10 Cm.) long.

Collection.—According to Dorat (1860, 1863) and Wyss (1878), at the beginning of the dry season, early in November or December, the bark for some distance up the trunk is beaten with the back of an axe or other blunt instrument until it has separated from the wood without breaking. This is done on four sides, leaving four intermediate strips untouched, so as not to destroy the vitality of the tree. Five or six days later the loosened bark is charred by means of torches, and in the course of another week the charred pieces fall off, when the bare wood is covered by rags, which absorb the exuding balsam, and which, when saturated, are gently boiled in water until most of the heavy balsam sinks to the bottom, the remainder being obtained by wringing the partly-exhausted rags in a bag made of stout rope. The wounds of the tree are covered with fresh rags as long as any balsam exudes during the dry season. The strips left untouched in one season are similarly treated the following year, and the tree will thus yield an annual supply of balsam for 30 years, but it is allowed to rest for some time after 5 or 6 years in order not to exhaust its productiveness. The balsam obtained from the rags by boiling and pressing is on the following day separated from the water and put into suitable vessels.

Commerce.—Balsam of Peru comes to us in earthen jugs and metallic drums, and is principally exported from the port of Acajutla on the Pacific coast and from Balize on the Atlantic side. Formerly it reached Europe by way of Peru, and was supposed to be a product of that country. The importation into the United States amounted in 1876 to 1271 pounds, and in 1878 reached 8924 pounds.

Description.—The balsam is a thick liquid of the consistence and appearance of molasses, of a dark brown-black color when examined in bulk; in thin layers, red-brown and perfectly transparent. It has an acid reaction, an agreeable, fragrant, slightly smoky odor and a warm bitterish taste, followed by a burning sensation in the fauces. Its specific gravity is 1.135 to 1.150 (1.137 to 1.145, *P. G.*). Exposed to the air, it is but little changed and scarcely thickened in the course of several years, but ultimately forms a soft solid. It is readily soluble in all proportions in pure acetone, absolute alcohol, chloroform, and glacial acetic acid, and with an equal bulk of alcohol and ether yields a clear solution, which on the further addition of the solvent becomes turbid and deposits a little resin. It yields a clear mixture with one-third its volume of carbon disulphide, but with more of the latter separates a blackish-brown resin. Petroleum benzin agitated with Peru balsam does not permanently mix with it, and remains colorless, but on evaporation leaves a colorless or pale-yellow oily liquid (cinnamein). Diluted alcohol and fixed and volatile oils dissolve only a small proportion of the balsam, but the latter takes up from 12 to 15 per cent. of castor oil, forming a clear solution.

By subjecting the fruit to pressure *white Peru Balsam* is obtained. It forms a thick yellowish-white liquid having an odor resembling that of tonka, and containing a crystallizable resin named *myroxocarpin*.

The tree exudes a gum-resin which, according to Attfield (1864), contains 77.4 per cent. of resin, but no aromatic principle or cinnamic acid.

Constituents.—The balsam has (1869 and 1870) been examined by K. Kraut and by J. Kachler, from whose analyses it appears to contain a little benzylic alcohol, benzylic benzoate and cinnamate (about 60 per cent.), cinnamic and benzoic acids, and resin (32 per cent., Kachler). Kraut obtained in the distillate also stilbene. After complete saponification with potassa, Kachler obtained 20 per cent. of benzalcohol and 46 per cent. of cinnamic acid. Delafontaine's statement (1868), that stryacin (cinnamylic cinnamate) is also present, was not corroborated by Kraut.

Benzylic cinnamate, or *cinnamein*, the principal constituent, has the composition $C_{11}H_{12}$ ($C_7H_7O_2$), and is when pure a colorless oily liquid of a faint agreeable odor and an aromatic sharp taste. Its specific gravity is about 1.095, and its boiling-point somewhat above 300° C. (572° F.). By caustic alkalies it is decomposed into benzylic alcohol and cinnamic acid.

Benzalcohol, or *benzylic alcohol*, C_7H_8O , is a colorless, faintly aromatic oil heavier than water and boiling at 204° C. (399.2° F.), and by oxidizing agents is converted first into oil of bitter almonds, and finally into benzoic acid. It is considered to be the *peruin* of Frémy in a pure state; as obtained by that author it was lighter than water.

Benzylie benzoate, $C_7H_5(C_7H_7O)_2$, is a colorless oil which crystallizes at a low temperature and boils at about $340^\circ C.$ ($674^\circ F.$).

Stilbene, $C_{14}H_{12}$, forms colorless and inodorous pearly scales or prisms which are fusible and boil above $290^\circ C.$ ($554^\circ F.$).

Adulterations.—Balsam of Peru is frequently adulterated with alcohol, fixed oils, copaiba, Canada turpentine, rosin, etc. Peru balsam should not diminish in volume when agitated with an equal bulk of water (absence of alcohol).—*U. S.* If 10 drops of the balsam be triturated with 20 drops of sulphuric acid, a tough, homogeneous, cherry-red mixture should result. If this be washed after a few minutes with cold water, it should be converted into a resinous mass which is brittle when cold (absence of fixed oils and oleoresins).—*U. S. P. G.* (For modifications in manipulation see *Am. Jour. Pharm.*, 1870, p. 404, and 1876, p. 166.) According to Schliekum (1882), the resin left on applying this test should be perfectly soluble in ether, an insoluble residue indicating the presence of benzoin or storax; treated with acetone or alcohol, such a residue will be completely dissolved unless storax was present, which will leave a small amount of a white powder undissolved, and yield it from chloroform in minute crystals. A mixture of 1 part of the balsam with 3 parts of disulphide of carbon separates from the balsam (about 40 per cent. of) black-brown resin. The liquid poured off from the latter should be transparent, should not have a deeper color than light-brownish, and should not exhibit more than a faint fluorescence (absence of gurjun balsam).—*U. S. P. G.* Flückiger states that the resin separated sometimes amounts to 38 per cent.; it is insoluble in ether, but dissolves in alcohol and alkalies, and, according to Kachler (1869), yields protocatechuic acid when fused with potassium hydrate, and on dry distillation yields styrol, toluol, and benzoic acid. When distilled with 200 times its weight of water no volatile oil should pass over (absence of volatile oil, copaiba, etc.).—*U. S. P. G.* The addition of volatile oils lessens the specific gravity of Peru balsam; on distilling it with water in a flask its volatile constituents remain behind, owing to their high boiling-points, while volatile oils distil with the vapors of water. If 1 Gm. of the balsam be agitated with 5 Gm. of benzoin, and after separation 30 drops of the clear liquid be evaporated spontaneously, a yellowish oily residue should be left, which on being moderately heated should not evolve an odor of turpentine, storax, or copaiba, and when mixed with 5 drops of nitric acid should not produce a blue or blue-green color either in the cold or at a moderate heat (absence of turpentines, storax, copaiba, fixed oils, etc.).—*P. G.* Benzoin, particularly when warmed with Peru balsam, takes up cinnamain, which after repeating the treatment may amount to 63 per cent. (Flückiger). The use of nitric acid in the above test was suggested by Doescher (1881); pure balsam gives a yellow color, but in the presence of storax the color is greenish-blue, and finally dingy green-yellow, and in the presence of rosin the same but brighter colors are produced. If 5 drops of the balsam be well agitated with 3 Ccm. of ammonia-water, only a slight, rapidly-disappearing foam should be produced, and the mixture on being set aside for 24 hours should not form a stiff jelly (absence of rosin, etc.).—*P. G.* By this test, which was proposed by Grote, turpentines and their resins are readily detected. Flückiger (1881) proposed the following: 10 drops of pure Peru balsam and 0.4 Gm. slaked lime form a mixture remaining soft, and which when warmed evolves a fatty odor in case castor oil or other fat be present.

Alcohol is best detected, according to Gavalowski (1875), by adding some of the suspected balsam to a solution of potassium bichromate, followed by concentrated sulphuric acid, when the characteristic odor of aldehyd, suggesting that of rotten apples, will be perceived. Or some of the balsam may be distilled with water and the distillate treated while warm with a little iodine, followed by caustic soda or potassa until decolorized. On cooling crystals of iodoform will separate (*Lieber's alcohol test*, 1869).

Pharmaceutical Uses.—Balsam of Peru is mixed with lard to preserve it from becoming rancid. A syrup is made of this balsam (see *SYR. TOLUTANUS*), and it is a constituent of the following:

MISTURA OLEOSO-BALSAMICA, s. *Balsamum vita Hoffmanni*, *P. G.* Three parts of balsam of Peru and 1 part each of the volatile oils of lavender, cloves, cinnamon, thyme, lemon, mace, and orange-flowers are dissolved in 240 parts of alcohol; after several days the brownish-yellow liquid is filtered.

Physiological Action and Medical Uses.—Balsam of Peru is a general stimulant, with a special tendency to the mucous membranes. In large doses it irritates the digestive canal, and may cause vomiting and diarrhœa; but in medicinal doses it occasions some heat of skin, increased frequency of pulse, and an augmented action of

the kidneys. Locally, it hastens repair of tissue, and is reputed to be a germicide and antiseptic. As an internal medicine it is most useful in limiting bronchial secretion, and hence as a remedy in *chronic bronchitis* occurring alone or as a complication of pulmonary consumption. It should not be used if much fever exists. It may be prescribed for these purposes by inhalation, and also for the alleviation of *chronic laryngitis*. In *chronic dysentery* its action is similar, and is often extremely salutary; and the same may be said of its use in the *diarrhoea* which is apt to persist in some cases of prolonged typhoid fever. As a dressing for various *ulcers*, especially those of the indolent sort, it promotes their cure by stimulation and by its protective agency. It is well suited for treating *sore nipples*, applied pure or in an ointment or liniment, for moderating the discharge of pus in *chronic catarrh* of the nostrils, ears, vagina, etc., and as an application to *chilblains*. In some cases of obstinate local *eczema* its healing virtues are conspicuous. According to circumstances it may be applied pure or diluted with glycerin, almond or olive oil, lard, etc. It speedily kills itch-insects and destroys their eggs. In Germany it is much used in the treatment of *scabies*, as being no less efficient, and much more agreeable, than sulphur for this purpose. It causes but little smarting or irritation of the skin. Before applying it the patient takes a prolonged warm bath, with or without green soap, after which, and three times a day for about 2 days, all the body, the seats of the eruption particularly, are rubbed with about 40 drops of the balsam. At the end of the time mentioned the cure is complete (Husemann). Balsam of Peru is one of the most useful of all applications for *pruritus vulvæ* and other forms of pruritus, especially the *senile*. It is best applied pure with the finger or with a soft brush. The addition of catechu improves its healing qualities in some instances. Internally it may be given in the dose of half a fluidrachm (Gm. 2) in an emulsion of almonds, gum-arabic, or yolk of egg, with sugar or dissolved in glycerin.

Hoffmann's balsam is used in Germany as a nervine in doses of from 10 to 30 drops (Gm. 0.30–1.00), on sugar, in wine, or in appropriate mixtures.

BALSAMUM TOLUTANUM, U. S., Br.—BALSAM OF TOLU.

Baume de Tolu, Baume de Carthagène, Fr.; Tolubalsam, G.

A balsam obtained from *Myroxylon toluifera*, *Kunth*, s. *Myrospermum toluiferum*, *A. Richard*, s. *Toluifera Balsamum*, *Miller*. Woodville, t. 215; Bentley and Trimen, *Med. Plants*, 84.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—This evergreen tree attains a height of 70 to 80 feet (21 to 24 M.), rising usually to about 40 or 60 feet (12 or 18 M.) from the ground without branching. Young trees always have a larger foliage than old ones, in which it is small and quite thin if they have been much bled. The leaflets are obovate, the flowers axillary-racemose, and the legume oblong-linear, not narrowed at the base. The tree is found in the high rolling country of Venezuela and New Granada. Prof. Baillon regards the tree yielding Peru balsam as identical with this, and the difference of the two products as due to the manner in which they are extracted (*Am. Jour. Pharm.*, 1874, p. 14).

Collection.—Two sloping notches are cut through the bark, meeting at their lower ends in a sharp angle, below which the bark and wood are hollowed out a little to receive the calabash cup into which the balsam flows. Similar cuts are made as high up as a man can reach, until often as many as twenty cups are found on one tree. When the lower part of the trunk is too full of scars a rude scaffold is sometimes made around the tree and new incisions made higher up. The balsam-gatherer collects the contents of the cups in flask-shaped bags made of raw-hide, a pair of them being slung over the back of a donkey. When filled these bags are sent to the ports of exportation on Magdalena River, where their contents are transferred into cylindrical tins (*John Weir, Am. Jour. Pharm.*, 1864, p. 449).

Commerce.—Tolu balsam is exported from the Venezuelan ports in tins holding 10 (and occasionally 25) pounds. The amount imported into the United States varies considerably. In 1876 it was 9221 pounds, and in 1880, 52,085 pounds.

Description.—Recently imported, Tolu balsam forms a semi-liquid mass which gradually hardens, becoming quite brittle in the cold, but softening between the teeth and fusing readily at a somewhat elevated temperature. In thin layers it is perfectly transparent and of a yellowish- or reddish-brown color. Viewed under the microscope, crystals of cinnamic acid are observed. It has an acid reaction, an agreeable aromatic odor, suggesting that of vanilla, which becomes more apparent on warming it, and a mild aromatic

taste. It is readily soluble in alcohol, chloroform, potassa solution, and acetone; also in ether. Petroleum benzin, benzol, and carbon bisulphide scarcely act upon it.

Constituents.—The main constituent of Tolu balsam is an amorphous resin which, according to Kopp (1849), consists of a portion very soluble, and another but slightly soluble, in alcohol. Cinnamic acid, to the exclusion of benzoic acid, was found by Kopp (1849), Carles (1844), but Busse (1876) proved also the presence of benzoic acid and 8.5 per cent. of benzylic ethers of cinnamic and benzoic acids. On distillation with water about 1 per cent. of *tolene* is obtained, which is a colorless, thin, volatile oil boiling at 160° C. (170°, Deville), having a specific gravity of .858, an agreeable odor, an acrid peppery taste, and the composition $C_{10}H_{16}$. Dry distillation yields, in addition to the ethers and acids named above, also styrol (see STORAX), phenol (see page 39), and toluol.

Toluol, or *toluene*, C_7H_8 , is *methylbenzol*, $C_6H_5.CH_3$. It is found in coal-tar and among the products of destructive distillation of wood, various resins, and many organic compounds. It is a colorless, oily, strongly refractive liquid, of the spec. grav. .86, boiling at 111° C. (231.8° F.), and not congealing at -20° C. (-40° F.). Its odor is similar to that of benzol. By suitable treatment it is converted into benzoic acid. (See page 35.)

Adulterations.—Turpentine is sometimes added, and may be detected by their solubility in carbon bisulphide. Concentrated sulphuric acid imparts to pure Tolu balsam a cherry-red color; in the presence of turpentine the acid becomes black. Naylor (1878) met with a spurious balsam of Tolu, which had a warm acrid taste, and was completely soluble in carbon bisulphide, benzol, chloroform, ether, and hot alcohol: its origin is unknown.

Pharmaceutical Uses and Preparations.—Balsam of Tolu is used as a vehicle in *Pilule phosphori*, *U. S. Br.* *Syrupus toluianus*, *U. S. Br.*, contains mainly the aromatic principle; and in *Tinct. toluana* and *Tinct. benzoini comp.*, *U. S. Br.*, balsam of Tolu is completely dissolved in the alcoholic menstruum.

Allied Plants.—MYROXYLON PUNCTATUM, *Klotzsch*, s. *Myrospermum balsamiferum*, *Ruiz et Pavon*, s. *Toluifera punctata*, *Baillon*, is the *quino-quino* tree of Peru, and by Bentley, Flickiger, and others is regarded as not being distinct from the tolu balsam tree.

MYROXYLON PERUVERIUM, *Linne filius*, s. *M. pedicellatum*, *Klotzsch*, s. *Toluifera peruifera*, *Baillon*. Peckolt (1879, 1880) showed that a balsam resembling Peru balsam may be obtained from it, which, however, has only the spec. grav. 1.031, an aromatic, astringent, and slightly pungent taste, yields clear solutions with alcohol and castor oil in all proportions, and with sulphuric acid does not yield a brittle resin, but a sticky, somewhat greasy mass.

Physiological Action and Medical Uses.—The general properties of balsam of Tolu resemble those of balsam of Peru, but are much less decided. Its agreeable flavor renders it an eligible ingredient of mixtures, lozenges, vapors, etc. intended to modify subacute and chronic inflammations of the mucous membrane, especially the *bronchial*. It is much used by perfumers in the manufacture of burning pastilles. It may administered in emulsion in doses of from 10 to 30 grains (Gm. 0.60–2.00). Its most usual form in medicine is the syrup.

BAPTISIA.—WILD INDIGO.

Indigo sauvage, Fr.; *Baptisie*, G.

The root of Baptisia (*Sophora*, *Linne*, *Podalyria*, *Michaux*) tinctoria. *R. Brown*.

Nat. Ord.—Leguminosæ, Papilionacæ.

Origin.—Wild indigo is a common, smooth, perennial herb growing in dry, sandy ground in the United States and Canada. The branching stem is about 2 feet (60 Cm.) high; the leaves are trifoliate, the leaflets roundish-ovate and wedge-shaped at base; the stipules minute and caducous; the yellow flowers are in small, loose racemes. On drying, the herb becomes bluish-black.

Description.—The root consists of a short, knotty head which is 2 to 3 inches (50 to 75 Mm.) broad, with irregular and broad stem-scars above, and below divided into several long cylindrical branches about ½ inch (12 Mm.) in diameter, which are sparingly beset with branching fibres. The bark is externally of a dark-brown color, with small warts somewhat arranged in transverse rows or with a soft and friable corky layer; internally whitish, radially striate, thick, and covering a whitish, tough, and tasteless wood with indistinct medullary rays. Roots of 1 year's growth are smaller, of a light-brown color externally, and have the ligneous medullium about as thick as the bark. The root is nearly inodorous and has a bitterish, acrid, and nauseous taste residing in the bark.

Constituents.—Wild indigo-root contains resin, but no volatile or fixed oil (Smedley, 1862). An alkaloid, of which the hydrochlorate has a nauseous and acrid taste, was obtained by J. A. Weaver (1871). Dr. F. V. Greene (1879) found the alkaloid to be insoluble in chloroform, benzin, and benzol, but to dissolve in water, alcohol, and ether.

Medical Action and Uses.—Its young shoots, like those of *phytolacca*, have been eaten in the same manner as asparagus. When more mature the stalks and roots are violently emetic and cathartic, especially when fresh. A decoction of the bark has like effects. Rutherford's experiments led him to conclude that "in the dog it is a hepatic and also an intestinal stimulant of moderate power." It would seem to be a general stimulant, since it has been held in great repute as a remedy in *scarlatina*, *typhus*, and epidemic *dysentery*, and also as a topical application in *aphthæ*, *mercurial sore mouth*, and various *ulcers*, especially those affected with gangrene. For the last-mentioned purpose it has been used in a poultice or an ointment. The leaves possess the same virtues as the root, but in a less degree. A tincture of the root, in the dose of from 1 to 5 drops every 1 to 4 hours, is credited with "almost entirely preventing delirium and diarrhœa, diminishing the heat and soon effecting a cure" of *typhoid fever*. But as it was associated in the treatment with "cool lotions, milk, and stimulants," it cannot be credited with the alleged results, which, indeed, are incompatible with the law of typhoid fever (*Am. Jour. Pharm.*, l. 89). Wild indigo is given in decoction made with an ounce of the recent root to a pint of boiling water; the dose is about a tablespoonful (Gm. 16) every 3 or 4 hours; its tendency to occasion vomiting and purging may be diminished by lessening the dose or adding laudanum to the liquid.

BARIUM.—BARIUM.

Barium, E., G.; *Baryum*, Fr.

Symbol Ba. Atomicity bivalent. Atomic weight 136.8.

Origin.—The mineral *heavy spar* first attracted attention about 1602 through the discovery of a phosphorescent compound obtained by igniting a mixture of the mineral and organic substances. The presence in the mineral of sulphuric acid was demonstrated by Marggraf (1750), and of a peculiar earth by Scheele (1774) and Gahn (1775). Crawford (1787) first used the barium chloride medicinally. An amalgam of barium was obtained (1808) by Berzelius and Pontin, and in the same year Davy isolated the metal by distilling the mercury from the amalgam.

Properties.—Barium is a lustrous, light-yellow metal of the spec. grav. 3.6, and is rapidly oxidized on exposure to air and in water. The following compounds are more or less employed in medicine, in chemistry, or in the arts:

1. **BARI HYDRAS.**—Barium hydrate, E.; Hydrate de baryte, Fr.; Barythydrat, G. Formula BaH_2O_2 . Mol. weight 170.8.—*Oxide of barium* is first prepared by calcining barium nitrate, or a mixture of this salt with barium sulphate; the oxide is dissolved in water, the solution decanted, if necessary, from the insoluble matter, then evaporated to dryness and heated to redness. It forms a white crystalline mass or a white powder, has the spec. grav. 4.5, a strong alkaline reaction, and is freely soluble in water. It is employed for the decomposition of sulphates, carbonates, etc. Its purity is determined in the same manner as that of barium carbonate; it does not effervesce with acids.

2. **BARI PEROXIDUM.**—Barium peroxide, E.; Peroxyde de baryum, Fr.; Barium hyperoxyd, G. Formula BaO_2 . Mol. weight 168.8.—It is prepared by conducting oxygen or atmospheric air over barium oxide or hydrate heated to dull redness. It is a gray porous mass or white powder, which parts with O at a bright-red heat, and with hydrochloric acid yields hydrogen dioxide.

3. **BARI CARBONAS.** *U. S.* 1870; Barium carbonicum, *Baryta carbonica*, *Carbonas baryticus*.—Carbonate of barium, E.; Carbonate de baryte, Fr.; Kohlensaures Barium, Kohlensaurer Baryt, G. Formula BaCO_3 . Mol. weight 196.8.—Carbonate of barium is found native, as *witherite*, in large quantities in the lead-mines at Alston Moor and at Anglesark in Lancashire, England. It is also met with in Scotland and Sweden. It may be obtained artificially by precipitating a soluble barium salt with an alkaline carbonate, or by heating to redness and fusion a mixture of 10 parts of heavy spar (barium sulphate), 2 of carbon, and 5 of potash, and washing the fused mass with water, when barium carbonate is left behind. Its formation is explained by the following equation: $\text{BaSO}_4 + \text{C}_2 + 2\text{HKO} = \text{BaCO}_3 + \text{K}_2\text{S} + \text{CO}_2 + \text{H}_2\text{O}$.

Witherite is found in pale-yellowish or grayish fibrous masses or in rhombic crystals

varying in specific gravity between 4.3 and 4.56. The artificially-prepared barium carbonate forms a soft, white, amorphous or crystalline, tasteless powder. Its specific gravity is 4.22 to 4.307. It requires over 15,000 parts of boiling water for solution, but dissolves more readily in solutions of chloride and some other salts of ammonium, and is also slightly soluble in some carbonates, and even sulphates. When recently precipitated it decomposes the solutions of many salts, precipitating the metals either as hydrates or carbonates. Owing to its solubility in hydrochloric and other acids, it acts as a poison when taken internally.

Barium carbonate should be completely soluble, with effervescence, in dilute hydrochloric acid (absence of barium sulphate). The solution is not colored or precipitated by ammonia or hydrosulphuric acid (absence of lead and other metals). When the solution is precipitated by an excess of sulphuric acid the filtrate, on being evaporated, should leave no fixed residue (absence of alkalies), and should yield no precipitate with carbonate of sodium (absence of calcium and other earths).

4. *BARIUM SULPHAS*.—Heavy spar, *E.*; Spath pesant, *Fr.*; Schwerspath, *G.* Formula BaSO_4 . Mol. weight 232.8.—This is a mineral from which other barium compounds are prepared by converting it first into soluble sulphide in the manner indicated below; on treating its solution with dilute sulphuric acid, sulphate of barium is again formed, and this is used under the name of *permanent white* or *blanc fix* for glazing cards and by painters in place of white lead.

5. *BARIUM CHLORIDUM*, *U. S.* 1870; Baryum chloratum, Baryta muriatica.—Chloride of barium, *E.*; Chlorure de baryum, *Fr.*; Chlorbaryum, Chlorbarium, *G.* Formula $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$. Mol. weight 243.6.—It is prepared by dissolving barium carbonate in diluted hydrochloric acid, evaporating the solution, and crystallizing. On the large scale it is obtained sometimes as a secondary product, as in the preparation of ammonium carbonate (see page 177), or it is made from native sulphate of barium (heavy spar) by igniting its mixture with charcoal, so as to form barium sulphide, and carbonic acid, according to the equation $\text{BaSO}_4 + \text{C} = \text{BaS} + 2\text{CO}_2$. The barium sulphide thus obtained is then dissolved in water and boiled with some excess of hydrochloric acid, whereby sulphuretted hydrogen is given off, barium chloride remaining in solution: $\text{BaS} + 2\text{HCl}$ yields $\text{BaCl}_2 + \text{H}_2\text{S}$. By evaporating the solution the salt is obtained in crystals.

Barium chloride exists in colorless, translucent rhomboidal tables or lamellæ. It is permanent in the air at the ordinary temperature, but loses one-half of its water above 55°C . (131°F), and becomes anhydrous at 121°C . (250°F). 100 parts of water retain at 105°C . (221°F) 60 parts, at 40°C . (104°F) about 41, at 20°C . (68°F) 35.7, and at 10°C . (50°F) 34.3 parts of the salt in solution (Mulder). The aqueous solutions are partly precipitated by strong hydrochloric and nitric acids, in which the salt is less soluble than in water. It is insoluble in absolute alcohol, but dissolves in spirit containing water, and imparts to the alcohol-flame a yellow color. It possesses the persistently bitter and disagreeable astringent taste of the soluble barium salts. Its solution yields with nitrate of silver and with potassium sulphate or dilute sulphuric acid copious white precipitates, which are insoluble in nitric acid. Phosphates, carbonates, and the salts of most organic acids yield with barium chloride precipitates which are insoluble in water, but dissolve in nitric or hydrochloric acid.

(Chloride of barium should be entirely soluble in water (absence of barium carbonate and sulphate), and the solution should not be colored or precipitated by ammonia or hydrosulphuric acid (absence of lead and other metals). When precipitated by an excess of sulphuric acid the filtrate should leave no fixed residue on evaporation (absence of alkalies), and should yield no precipitate with sodium carbonate (absence of calcium and other earths). Alcohol shaken with the powdered salt, then poured off and ignited, should not burn with a red flame (absence of strontium chloride).

6. *LIQUOR BARIUM CHLORIDI*.—Solution of chloride of barium, *E.*; Soluté de chlorure de baryum, *Fr.*; Chlorbarium-Lösung, *G.*—Dissolve barium chloride 1 troyounce in distilled water 3 fluidounces, *U. S.* 1870.

7. *BARIUM BROMIDUM*.—Bromide of barium, *E.*; Bromure de baryum, *Fr.*; Brombarium, *G.* $\text{BaBr}_2 \cdot 2\text{H}_2\text{O}$. Mol. weight 332.8.—It is obtained on dissolving barium carbonate in hydrobromic acid, and crystallizes in colorless rhombic plates, which dissolve in their own weight of cold water and are freely soluble in alcohol. The salt has a very disagreeable taste.

8. *BARIUM IODIDUM*.—Iodide of barium, *E.*; Iodure de baryum, *Fr.*; Jodbarium, *G.* $\text{BaI}_2 \cdot 2\text{H}_2\text{O}$. Mol. weight 426.—It is conveniently made by boiling a solution of iodide of iron with excess of barium carbonate, filtering, and crystallizing. It forms large trans-

parent rhombic prisms which are very freely soluble in water and alcohol, and when heated melt and become anhydrous.

Physiological Action.—The soluble salts of barium are all supposed to possess closely analogous powers, but the sulphate, owing to its insolubility, is probably inert. Long ago Gmelin used this language: "The salts of barium are energetic poisons, having a special power of destroying the irritability of the voluntary muscles; they act upon the stomach as irritants, and also inflame the heart. The proper antidote for them is a soluble alkaline sulphate." Boehm's experiments, in which soluble barium salts were injected into the lymph-sacs of frogs, showed, as effects, mucous secretion from the skin; distension of the air-sacs, rigid extension of the limbs, convulsive movements under irritation, followed by relaxation and paralysis of the voluntary muscles first, and then of those of respiration; the abdomen was meanwhile tumid, and through its walls vigorous intestinal peristalsis was visible; the lungs were distended, and active irritation of the animal extorted from it a loud and unnatural cry. In mammals the injection of a strong solution of the salt into the veins immediately excites tonic and clonic convulsions, a discharge of urine and feces, and general paresis, or, if the dose has been excessive, death in convulsions may ensue. In the stomach the poison does not exhibit any effect for 15 or 20 minutes, when alvine evacuations take place, the abdomen is distended, and the peristaltic movements of the bowels are visible. In dogs profuse salivation occurs, with vomiting and prolonged straining. Gradually extreme muscular debility succeeds, and the pupils dilate, but perception does not appear to be extinct until death, which is attended with slight spasms. The action of barium salts upon the heart is essentially the same in frogs and mammals; it occasions a contraction of the heart and arteries, which is more or less prolonged according to the dose employed, and, as a consequence, augments the pressure of the arterial blood-column. If, however, the dose employed is excessive, the heart is paralyzed and not made rigid. Boehm concluded from his experiments that barium salts "either stimulate powerfully the whole nervous sympathetic system or have a special relation to unstriated muscular fibre."

We are not acquainted with any experiments upon man sufficient to illustrate the physiological action of these compounds, or which prove them to be tonic, diuretic, and diaphoretic, as they are said to be. It is true that Dr. F. Flint took "about 1 grain three times a day with a very marked stimulant effect" (*Practitioner*, xxiii. 40). It is certain that in an overdose chloride of barium may produce the symptoms common to the irritant poisons—abdominal pain, vomiting, purging, collapse with thready pulse, general muscular asthenia, coma, convulsions, and death. The most characteristic symptoms are labored respiration and bronchial effusion. After death the lesions in the stomach consist of vascular injection and extravasation, and even ulceration. The carbonate is said to have destroyed life in at least three cases. Of four persons who were poisoned by this compound, three suffered from weakness of the lower limbs; the fourth had paralysis of the legs and trunk, and death occurred on the second day. No lesions whatever were found in the stomach or bowels (Reinke, *Practitioner*, xxii. 49). In a case which ended in recovery the patient complained of dimness of sight, double vision, headache, tinnitus, and cramps, with occasional vomiting and purging. In another case the principal symptoms were numbness of the feet, cramps in the legs, and general coldness of the body (*Edinb. Med. Jour.*, xxviii. 651).

Medical Uses.—There is little in the summary above given of the action of the salts of barium to connect it with the therapeutic results which are said to have followed their administration in disease, unless, perhaps, it really have the power of "stimulating powerfully the whole nervous sympathetic system." Such an action might be admitted to explain the virtue attributed to it of curing *scrofula* of the glands. Hufeland claimed that in this affection its virtues "do not yield either to mercury or antimony;" which might very well be the case even if it were more injurious than useful. Yet a large number of writers might be cited who attribute to it a peculiar efficacy in *scrofula*. Among them, Phillips holds that as a local discutient it is not inferior to iodine, and that in cases where "the fallow-like complexion, the pale tongue, and the languid circulation, accompanied by irritability of the mucous surfaces, are present, its virtues are remarkably demonstrated." A later and a better authority, Lebert, declares that he has "never obtained the slightest advantage from its use" in glandular *scrofula*. And this experience, we apprehend, is more weighty than that of a multitude of less competent judges. In other forms of *scrofula* affecting the joints, eyes, etc. the evidence of its utility is, if possible, still less. Dr. F. Flint ascribes the apparent cure of an *aneurism* of the abdominal aorta to the administration of chloride of barium in doses of from $\frac{1}{2}$ to $\frac{2}{3}$ grain three times a day for

nearly 5 months. This took place after the diet-and-rest cure had been tried for an equal period without benefit (*Practitioner*, xxiii, 37). The virtues attributed to natural mineral waters containing barium salts in the treatment of *cutaneous diseases* are no doubt more or less real, but that they are in any degree due to the minute proportion of those salts present in the waters is a groundless hypothesis. The dose may be stated at from $\frac{1}{2}$ grain to 1 or 2 grains (Gm. 0.03–0.12) dissolved in a large quantity of water and taken after meals. Of the solution of chloride of barium the dose is about 5 drops (Gm. 0.30).

BEBERIÆ SULPHAS, *Br.*—SULPHATE OF BEBERIA.

Sulfate de bébérine, Fr.; *Schwefelsaures Beberin*, G.

Prepared from nectandra- or bebeeru-bark.

Preparation.—Take of Bebeeru-bark in coarse powder 1 pound; Sulphuric Acid $\frac{1}{2}$ fluidounce; Slaked Lime $\frac{3}{4}$ ounce or a sufficiency; Solution of Ammonia a sufficiency; Rectified Spirit 16 fluidounces or a sufficiency; Diluted Sulphuric Acid a sufficiency; Water 1 gallon; Distilled Water a sufficiency. Add the sulphuric acid to the water; pour upon the bebeeru-bark enough of this mixture to moisten it thoroughly; let it macerate for 24 hours; place it in a percolator and pass through it the remainder of the acidulated water. Concentrate the acid liquor to the bulk of 1 pint; cool, and add gradually the lime in the form of milk of lime, agitating well and taking care that the fluid still retains a distinct acid reaction. Let it rest for 2 hours; filter through calico; wash the precipitate with a little cold distilled water, and to the filtrate add solution of ammonia until the fluid has a faint ammoniacal odor. Collect the precipitate on a cloth, wash it twice with 10 ounces of cold water, squeeze it gently with the hand, and dry it by the heat of a water-bath. Pulverize the dry precipitate, put it into a flask with 6 ounces of the rectified spirit, boil, let it rest for a few minutes, and pour off the spirit. Treat the undissolved portion in a similar manner with fresh spirit until it is exhausted. Unite the spirituous solutions, add to them 4 ounces of distilled water, and distil so as to recover the greater part of the spirit. To the residue of the distillation add by degrees, and with constant stirring, diluted sulphuric acid till the fluid has a slight acid reaction. Evaporate the whole to complete dryness on the water-bath, pulverize the dry product, pour on it gradually 1 pint of cold distilled water, stirring diligently; filter through paper; evaporate the filtrate to the consistence of syrup, spread it in thin layers on flat porcelain or glass plates, and dry it at a heat not exceeding 140° F. Preserve the product in stoppered bottles.—*Br.*

The percolate obtained on treating bebeeru-bark with acidulated water contains, besides sulphate of beberine, beberic acid, which is almost completely removed by the lime. The filtrate, which is still acid, is treated with ammonia, whereby impure beberia is precipitated, together with some lime compounds. From this mixture alcohol takes up the alkaloid still contaminated with coloring matter, which is not removed by the subsequent treatment with sulphuric acid. But, after evaporating to dryness and redissolving in cold water, some foreign matters which are soluble in the acid solution remain on the filter.

Properties.—Thus prepared, sulphate of beberine (or *bibiria*) forms dark-brown, thin, translucent scales, yielding a brownish-yellow powder having a bitter taste and being completely soluble in water and in alcohol. The commercial salt yields with from 6 to 8 parts of water a clear solution, but on further dilution a precipitate is often occasioned, which J. Nesbit (1881) found to be due to a deficiency of sulphuric acid; on supplying this only a slight amount of oxidation-product remains undissolved. Dott (1881) found the scaly salt to contain about 15 per cent. of water, 7.8 per cent. of SO_3 , and about 60 to 64 per cent. of mixed alkaloids, the remainder being extractive and coloring matter. Pure sulphate of beberine is yellowish-white. The official salt contains also the sulphate of *spirine*, a second and brown alkaloid met with in the bark. Beberine was considered by Walz (1860) to be identical with buxine, the alkaloid of the common box; the statement was corroborated by Flückiger (1869), who established also the identity of pelosine with the two alkaloids. That solutions of the salts of these alkaloids are precipitated by certain acids and neutral salts has been repeatedly observed; Palm (1883) recommends the separation of beberine from the other alkaloids by precipitating its solution with sodium chloride. (See also NECTANDRA and PAREIRA BRAVA.)

Tests.—The official salt yields a white precipitate with chloride of barium, and with caustic soda a yellowish-white precipitate which is soluble in ether, and on evaporating the solvent is again left as a yellow translucent residue entirely soluble in dilute acids.

The salt is completely decomposed by heat, without leaving any fixed residue. These tests, in connection with the properties mentioned, are sufficient to prove the purity of the salt.

Physiological Action.—Administered hypodermically to frogs, it produces tetanic rigidity without exaggerated reflex excitability, in which respect it resembles quinine, caffeine, and theine, and differs from strychnine. Internally, it does not produce the headache, tinnitus, deafness, gastric irritation, etc. which quinine sometimes occasions, while it equals that alkaloid in its tonic influences upon the appetite and digestion.

Medical Uses.—Introduced as a substitute for quinine, it has not confirmed the estimate originally made of its efficacy: for although, like the greater number of vegetable bitters, it displays *anti-periodic* virtues, and like some of them also it will occasionally effect a cure of intermittent fever, yet on the whole its powers must be rated much lower than those of the cinchona salts. It has been found curative in some cases of periodical headache and neuralgia of the same type, and as a useful tonic in the general debility of pulmonary phthisis and of prolonged suppuration with *hectic fever*. In strumous ophthalmia, atonic dyspepsia, certain cases of menorrhagia, leucorrhœa, etc. it may be used as a substitute for quinine. The dose as a tonic is from 1 to 3 grains (Gm. 0.06–0.20); as an anti-periodic, from 5 to 10 grains (Gm. 0.30–0.60). It may be given, like sulphate of quinine, in a watery solution with an excess of aromatic sulphuric acid.

BELÆ FRUCTUS, *Br.*—BAEL-FRUIT.

Indian bael, Bengal quince, E.; *Bael*, Coing du Bengale, Fr.; *Belafrucht*, Bengalische Quitte, G.

The dried, half-ripe fruit of *Ægle Marmelos*, *Correa* (*Pharm. Jour.*, vol. x. p. 166, plate), s. *Crataeva Marmelos*, *Linné*, s. *C. religiosa*, *Ainslie*. Bentley and Trimen, *Med. Plants*, 55.

Nat. Ord.—Aurantiaceæ.

Origin.—The bael tree is a medium-sized thorny tree, with ternate leaves and large white flowers, indigenous to the Himalaya Mountains, but much cultivated throughout India.

Description.—The fruit is from 2 to 4 inches (5 to 10 Cm.) in diameter, more or less globular in shape, and resembles an orange of large size in appearance and internal arrangement, it being divided into about twelve cells, containing in the ripe state a pleasant-flavored, highly mucilaginous juice, while the rind is quite aromatic. As found in commerce, the fruit is mostly broken, a portion of the dried pulp and seeds still adhering to the fragments of the rind. The latter is smooth and of a brownish-gray color externally, about $\frac{1}{4}$ inch (3 Mm.) thick, hard, and of a slightly astringent taste, destitute of aromatic properties. The exposed portion of the dried pulp is of a deep-orange, red-brown, or bright brownish-red color, whitish within, hard, of a mucilaginous scarcely acidulous taste, and encloses in each cell several oblong, flat seeds, which are woolly and very mucilaginous.

Constituents.—These have not been well ascertained. The rind contains mucilaginous and pectin compounds, but appears to be free from tannin, which, according to Collas (1856), is found in the ripe fruit to the amount of 5 per cent. The infusion of bael is scarcely affected by iron salts.

Substitution.—The fruit of *Feronia elephantum*, *Correa*, another aurantiaceous tree of India, is used there like bael. It is known under the name of *elephant-* or *wood-apple*, and differs from bael in being completely divided into five compartments.

Off. Prep.—Extractum belæ liquidum, *Br.*

Medical Action and Uses.—Bael is, and long has been, used in India, where the British practitioners ascribe to it astringent, aromatic, and demulcent qualities. It enjoys in that country great repute, especially in the treatment of some forms of bowel complaint. The pulp of the fresh fruit is used with sugar to make a draught (sherbet) which, according to Waring, “is not only astringent when *diarrhœa* exists, but possesses the singular property of being also aperient if the bowels are *costive*.” The bark of the root and of the trunk of the tree is tonic and astringent; the expressed juice of the leaves “is commonly given in colds and incipient fevers when the patient complains of general dulness, pains in his limbs, and a sense of fulness in the stomach;” the young leaves are applied warm to the eyes in *ophthalmia*; and a decoction of the unripe fruit is prescribed in *diarrhœa* and *dysentery*. In chronic *diarrhœa* following typhoid fever Christison found it singularly efficient. He says: “It is an incomprehensible remedy, has neither aroma

nor taste, and certainly no astringency," in the dried state. The liquid extract appears to be the most available preparation of bael. It is recommended to be given in doses of 1 to 2 fluidrachms (Gm. 4-8) (Tayrer, *Times and Gaz.*, June, 1878, pp. 611, 645; July, 1878, p. 86).

BELLADONNA, U. S., Br., P. G.—BELLADONNA.

Deadly nightshade, Duale, E.; Belladone, Morelle furieuse, Fr.; Tollkirsche, Wolfskirsche, Tollkraut, Belladonna, G.

Atropa Belladonna, Linné. Bentley and Trinen, Med. Plants, 193.

Nat. Ord.—Solanaceæ, Atropeæ.

Officinal Parts.—1. BELLADONNÆ FOLIA, U. S., Br.; Folia (s. Herba) belladonnae, P. G.—Belladonna-leaves, E.; Feuilles de belladone, Fr.; Belladonna-Blätter, G.

The leaves.

2. BELLADONNÆ RADIX, U. S., Br.—Belladonna-root, E.; Racine de belladone, Fr.; Belladonnawurzel, G.

The root.

Origin.—Belladonna is a nearly glabrous, herbaceous, perennial plant, attaining a height of from 4 to 6 feet (1.2 to 1.8 Mm.), and has dark-purple bell-shaped flowers and glossy purplish-black berries of the size of a cherry. It is found in the woods, chiefly in mountainous districts, of Central and Southern Europe, and as far east as Asia Minor, Caucasia, and Central Asia. It is cultivated in Europe and in this country to a certain extent.

Description.—1. BELLADONNA-ROOT. As collected from plants several years old, the roots are a foot (30 Cm.) or more long. $\frac{1}{2}$ inch to 1 inch (12 to 25 Mm.) thick, cylindrical above and gradually tapering, fleshy, and in the dry state with deep longitudinal wrinkles. The head is frequently crowned with the hollow bases of the overground stems; the bark is covered with a brownish-gray cork, or, after its removal, is of a light

gray or grayish-white color externally and somewhat lighter internally. A fine blackish cambium-line separates the bark from the medullium, in which the small yellow wood-bundles, with large vessels, are arranged in radiating wedges, separated by rather broad medullary rays; near the centre and in the young branches the wood-bundles are loosely scattered around

FIG. 38.

Atropa Belladonna, Linné: branch, fruit, seed, and section of seed, the last two magnified.

FIG. 39.

Belladonna-root: transverse section.

a central ligneous cord, while in the old roots the woody tissue predominates considerably. When fresh the root has a disagreeable, heavy odor, which disappears on drying, leaving merely a faint earthy smell. The taste is not very

marked, being at first sweetish, with a bitterish and somewhat acrid after-taste. The fracture of young roots is nearly smooth and mealy, of old roots woody and tough. Young branches, peeled and dried, have some resemblance to marshmallow-root. (See ALTHÆA.) Belladonna-root is best collected at or shortly after the flowering period; from old plants only soft root-branches should be preserved, but tough woody roots, which are sometimes 2 inches (5 Cm.) and more thick, should be rejected for pharmaceutical use. The former German Pharmacopœia directed the root to be kept not more than 1 year.

2. BELLADONNA-LEAVES.—The forking stem bears above numerous bright-green, broadly ovate or ovate-oblong leaves, with the margin entire, and arranged in unequal

pairs, one being about one-half the size of the other. They attain a length of 4 to 6 inches (10 to 15 Cm.; not over 20 Cm., *P. G.*), are about one-half as wide, are tapering toward the apex and narrowed at the base into the petiole, $\frac{1}{2}$ to 1 inch (12 to 25 Mm.) in length. The leaves are entirely smooth, a slight downiness on the nerves beneath excepted. They lose about 85 per cent. and become thin and papyraceous in drying, the upper surface readily assuming a brownish tint, the lower becoming grayish-green; they show, particularly on the lower surface, a whitish granular appearance under the magnifying-glass. Circular holes, resulting from the separation of suberous warts, are frequently observed. The heavy odor of the fresh leaves disappears on drying almost completely, but it is somewhat restored by moisture; the taste is slightly saline, bitterish, and nauseous.

Admixtures.—The root of *Medicago sativa*, *Linneé*, has been observed as an adulteration of belladonna-root; it resembles the latter, but branches of the crown are solid, the bark is thinner, and the medullium is tough, woody to the centre, and traversed by numerous fine medullary rays. Leaves of *digitalis*, *hyoscyamus*, *verbascum*, and other plants, occasionally met with in carelessly-gathered belladonna, are easily distinguished by their characters, particularly the hairs. The leaves of *Solanum nigrum*, *Linneé*, are smaller, with the margin repand-dentate. In some parts of Southern Europe the oblong-obovate leaves of *Scopolia atropoides*, *Schultes* (s. *Hyoscyamus Scopolia*, *Linneé*), are said to be collected with belladonna. They are stated to possess the same medicinal properties.

Constituents.—The most important principle contained in both belladonna-root and herb is atropine, the complex nature and chemistry of which have been described above. (See *ATROPINA*.) Estimated by iodohydrargyrate of potassium, Lefort (1872) found young roots to contain 0.6, old roots 0.25, and dry leaves, both cultivated and wild-grown, collected in the flowering period, 0.44 per cent. of atropine. Buddel (1882) obtained from amylaceous belladonna-root from .41 to 1 per cent., and from non-amylaceous root between .143 and .625 per cent., of alkaloid. The alkaloids are probably combined with malic acid. Besides the usual vegetable constituents, albumen, gum, etc., the root contains *atrosin*, a red coloring principle found also in the berries, according to Hübschmann. Young roots contain a considerable amount of starch, which is present to a more limited extent in older and more woody roots, and, according to W. Merz, is almost entirely wanting during summer; the young roots are said to contain more starch in autumn than in spring. A comparative examination of air-dry tough and soft roots, made by E. M. Holmes (1882), gave—

	Moisture.	Ash, soluble.	Ash, insoluble in water.	Alcohol extract.	Water extract.	Mayer's test, proportion.
Woody roots,	7.94	3.43	4.60	22.53	15.96 p. ct.	6
Soft roots,	10.28	2.20	3.68	29.87	10.50 "	10

The herb contains asparagin, which sometimes crystallizes in the extract (Biltz, 1839). By dialysis Attfield (1862) obtained crystals of potassium nitrate and of an organic magnesium salt. Flückiger found the ash of dry leaves to amount to 14.5 per cent., and to consist mainly of calcium and alkaline carbonates.

Pharmaceutical Uses and Preparations.—Belladonna-root is used in making *Atropia*. *Br.*; *Abstractum belladonnæ*, *Emplast. belladonnæ*, *Extract. bellad. fluid.*, *U. S.*; and *Linim. belladonnæ*, *Br.* The following preparations are made from the leaves: *Extract. bellad. alcohol.*, *U. S.*; *Ext. belladonnæ*, *Br.*; *Tinct. belladonnæ*, *U. S. Br.*

Allied Plants.—*ATROPA MANDRAGORA*, *Linneé*, s. *Mandragora officinalis*, *Miller*, s. *M. vernalis*, *Bertero*, and *M. autumnalis*, *Bertero*.—Mandrake. *E.*: *Mandragore*, *Fr.*: *Alraunwurzel*, *G.*—These acaulescent plants are indigenous to Southern Europe, where their roots are employed. They are 2 to 3 feet (60 to 90 Cm.) long, conical, sometimes forked, an inch (25 Mm.) or more thick; in the fresh state fleshy, whitish, and of a heavy narcotic odor; in the dry state wrinkled, externally brown, but internally whitish, showing a thick bark, and in the medullium distant and narrow yellow wood-bundles. They have a sharp and bitter taste and a narcotic action. They are rarely met with in this country.

SCOPOLIA JAPONICA, *Maximowicz*, *Japanese acnite-root*, has appeared in commerce, and was described by Holmes (1880). It is a nearly cylindrical oblique rhizome about 4 inches (10 Cm.) long and $\frac{1}{2}$ inch (12 Mm.) thick, on the upper surface marked with circular slightly alternate stem-scars, and below, on the node, with one or more rows of root-scars; it is externally brown, internally pale-brown, horn-like in appearance and with numerous whitish dots; has a mousy and narcotic odor and a slight bitter taste. It contains an alkaloid which Langgaard (1881) found to belong to the atropine group.

Physiological Action.—*On Animals* : Birds and herbivorous animals eat the fruit of belladonna without injury, and the latter excrete its active principle with the urine. Yet in the latter animals, but not in birds, the application to the eye of belladonna, or of the urine of animals eating it, causes dilatation of the pupil. It has been suggested that the innocuousness of belladonna in the cases just referred to is due to the active principle being modified by the digestive action of the stomach, but the animals which cannot be poisoned by belladonna in the stomach are equally insusceptible to its action when it is introduced directly into the blood. Nevertheless, their pupils become dilated by belladonna. Birds, as stated, are an exception. This is one of the many examples which show the danger of concluding from the lower animals to man in regard to the uses of medicines, unless the mode of action in the two cases is first proved to be identical. When belladonna, in the form of an extract, is given to dogs or injected into their veins, they exhibit, along with dilated pupils, evidences of suffering, retching or vomiting, generally muscular debility, dulness of the senses, and increased frequency and force of the heart's action. Death appears to be produced by exhaustion, but only after very large doses. In no animal is there any degree of that delirious excitement which belladonna produces in man.

On Man : The first and simplest effect of belladonna in small doses is to dilate the pupil, whether it be applied locally (in which case its action may be confined to one eye) or when taken internally. It is remarkable that no notice appears to have been taken of this property of belladonna until Ray (in 1686) related that, having dressed an ulcer of the face with the leaves of the plant, he observed that the pupil became dilated, and that the same effect was reproduced on two other occasions (*Histor. plantar.*, i. 680). Recorded cases show that a solution of atropine instilled into the ear or a belladonna plaster applied to the side of the chest has produced dilatation of the corresponding pupil only. The continued use of small doses internally occasions also dryness of the throat and a pink efflorescence of the skin closely resembling that of scarlatina; still larger doses excite a peculiar delirium, which will be presently described. All of the characteristic phenomena have been occasioned by the application of belladonna plasters and liniments to the skin, especially when the cuticle was broken, and in an infant by the milk of a female who had taken a large dose of the drug. The following is a summary of the effects of belladonna upon the several physiological elements of the economy. *On the nervous system* : A sense of tightness or pain is felt in the forehead and eyes, with giddiness, confusion of thought, and noises in the ears. The sight is confused, objects are hazy or their character is mistaken. Often they appear to be much smaller than natural. Spectral illusions, generally of a pleasing character, are frequent, such as jewels, flashes of colored light, birds of brilliant plumage, and insects with enamelled wings. In other cases they have the hideous appearance of the phantasms of delirium tremens. Sometimes there is a total blindness of several days' duration, and even after all mental disorder has subsided. The mind is apt to be filled with extravagant ideas; there is often delirium, which is generally of a gay description, and which prevents sleep or disturbs it with fantastic dreams. Sometimes the patient is quite conscious of his illusion and delirium, but is without the power to control either of them. The latter may be characterized by the incessant repetition for hours of some habitual act or phrase; sometimes, though rarely, it is violent, maniacal, and attended with injury to one's self or the attendants; but, in general, poisonous doses of the drug give rise to active and, for the most part, joyous delirium. It is a powerful anæsthetic; in a case of poisoning by it ending in recovery there was almost a total loss of sensibility of the skin, lasting for several days. It has no direct soporific operation. *On the muscular system* : Belladonna in excessive dose renders the gait unsteady and staggering, producing numbness with trembling and jerking movements of the limbs; the patient unconsciously runs against objects in his way or avoids encountering imaginary ones; he is unable to co-ordinate his movements or to pick up small objects. The pupil is dilated, the eye bright, the voice husky, or deglutition, owing to dryness of the throat, is impossible; the bladder is paralyzed and the urine retained, or both this secretion and the feces may be passed involuntarily. The upper eyelid is apt to be paralyzed, and may remain so for months. *On the circulation and secretions* : Under the action of full doses of belladonna the pulse is at first slower and fuller, contrary to what takes place in the lower animals after the subcutaneous injection of atropine, but afterward becomes more frequent, as well as more feeble, until in fatal cases it grows thready and intermittent. During the active period of the operation the whole capillary circulation would seem to be congested, for the external mucous membranes are dry, the face is red and turgid, there is a sense of fulness in the head, with throbbing of the arteries, as if the blood were

prevented from returning to the heart by a ligature around the neck. But the intracranial pressure does not appear to be increased in a like proportion (Jacobi). The general dryness of the skin and throat and larynx contrasts with the greatly augmented secretion of the kidneys during the active stage of belladonna-poisoning. This diuresis has been attributed to the fact that the active principle of the drug is excreted with the urine, and almost exclusively in this manner. Irritation of the scrotum sometimes exists in a high degree. Cases of fatal poisoning by belladonna are few in number. A lad of sixteen died from a drachm of the extract, and a woman of sixty-six after swallowing "a teaspoonful of belladonna liniment." A woman, having taken $\frac{1}{2}$ ounce each of lin. belladonnæ and lin. aconiti (*Br. Phar.*), died in spasms within half an hour (*Edinb. Med. Jour.*, xxvii. 443). A man, having liquefied an ointment containing $2\frac{1}{2}$ drachms (Gm. 10) of extract of belladonna, injected it into his bowel. He voided a portion of it, but the remainder caused the most marked symptoms of belladonna-poisoning. Recovery ensued without special treatment (*Bull. de thérap.*, ci. 239). A case of morphine-poisoning in an infant six weeks old is related by Dr. Chew (*Med. Record*, xix. 38). The first signs of reaction followed the administration of belladonna, and consisted in a bright scarlet flush of the skin. Children have a remarkable tolerance of belladonna. After death by belladonna or atropine the lungs and right side of the heart are engorged, the brain and meninges are congested, and the retina is hyperæmic, and a corresponding condition of the spinal cord has been observed.

Although it is impossible to present a clear and consistent rationale of the mode of action of belladonna in producing the phenomena that have been enumerated, it may be proper to state the most plausible views upon the subject. Like all other medicines which act directly through the nervous system, small and large doses of belladonna produce opposite effects, the former stimulating, the latter paralyzing it. The direct action of small doses upon the heart is to increase the vigor and the frequency of its contractions; but large doses render the pulse still more frequent, but more and more feeble and thready. Under moderate stimulant doses the number of visible capillary vessels is increased, owing, it is alleged, to the greater force with which the blood is propelled; but the individual vessels are said to undergo such a contraction (?) at the same time that the amount of blood in the part is diminished rather than increased. The continued use of such doses or the immediate administration of larger ones produces general dilatation of the capillary vascular system. Mr. T. W. Jones seeks to explain this effect by saying that constriction of the small arteries is the cause of the venous engorgement, and that the latter occasions the cerebral and muscular disturbance (*Amer. Jour. of Med. Sci.*, Apr. 1881, p. 362). This blood-stasis accounts for the dryness of the mouth and the redness of the skin, but it is not quite easy to explain by its means the absence of dryness of the external integument, nor the increased secretion of urine and bile, nor the greater facility of defecation, which are effects of medicinal doses of the medicine. The alleged hypnotic power of medicinal doses of belladonna may be referred to the diminution of blood which it occasions in the cerebral vessels; and in like manner the insomnia, hallucinations, blindness, etc. which large doses induce may be attributed to the hyperæmia which they cause in the brain. The anodyne and anæsthetic powers of belladonna appear to be inherent, and not the indirect result of changes in the blood-supply. On the other hand, the spinal symptoms, as shown after toxic doses by the suspension of mental control over movements and their co-ordination, seem to result from impaired sensibility and motility.

Medical Uses.—Belladonna is probably powerless to remove any sort of malignant tumor, but it very certainly does retard the growth and lessen the pain even of cancers, and promote the removal of some other tumors, especially the glandular, which are susceptible of absorption. It may be presumed to do this by lessening the blood-supply, and thereby restricting the nutrition of the morbid growth and its pressure upon the sensitive nerves. The virtues of belladonna in certain forms of *neuralgia* illustrate the folly of too rapidly generalizing. The relations of opium to pain of all descriptions are so nearly identical that it was naturally to be inferred that the same was true of belladonna; and yet there is only one form of uncomplicated pain, neuralgia, in which this medicine is of much service as a direct anodyne, and one variety of that form chiefly. It is a powerful remedy for neuralgia, but almost exclusively for neuralgia of the face and head. It is next most useful in intercostal neuralgia, then in visceral neuralgia, and least of all in sciatica. It should be given internally to the production of slight constitutional effects, while local applications of belladonna in ointment or liniment are made upon the sound or blistered skin, or atropine is hypodermically employed. The application of a belladonna plaster—or, still better, of a plaster of belladonna and conium—over the heart is of

signal service in many cases of the pain which is usually felt near the apex and is associated with palpitation, depending upon functional oftener than upon organic disease, and which is probably neuralgic.

The physiological action of belladonna, as revealed by experiments, is far from pointing clearly to one of the most useful applications of the drug in *relaxing spasm*, which has long been well known as a clinical fact. Sometimes, doubtless, it is difficult to disengage from this symptom the often-associated element, pain, which by turn excites and is produced by spasm. This is evidently the case in spasm of the *sphincter ani* and of the *urethra*, and probably in spasm of the *gall-ducts*, the *ureters*, the *bladder*, the *intestines*, and the *uterus*. It is probably so in pain depending upon muscular spasm in *rheumatism* and in that caused by the irritation of wounded and inflamed *nerves*. But the consideration of other cases of spasm without pain shows that the direct antispasmodic power of the medicine is very great. It will not be pretended that spasm of the *os uteri* during labor is the effect of the pain which accompanies it, and yet belladonna overcomes the rigidity in question, probably in the same manner in which it may be overcome by venesection. It is said to control nocturnal *seminal emissions* depending upon an over-excited state of the genital organs, and not on their mere debility. It is alleged that the medicine relieves *jaundice* supposed to be caused by the presence of inspissated bile in the ducts, but not necessarily occasioning pain; strangulated *hernia* is said to have been cured by local applications of belladonna, as it also has by the internal use of the drug (*Boston Med. and Surg. Jour.*, Nov. 1882, p. 419), and also *phimosis* and *paraphimosis*; and its relaxing influence on the bowels has frequently been resorted to successfully in cases of *obstinate constipation*, and especially in *lead colic*. The purely antispasmodic operation of the medicine is still more clearly seen in *whooping cough*. It should not be used until the inflammatory stage of the disease has declined, and then in doses not exceeding, at first, the eighth of a grain twice a day. The dose should be gradually increased until the pupils exhibit its effects. In other *nervous coughs* it is equally available, especially in such as depend upon laryngeal irritation. In *spasmodic asthma* it is one of the most reliable remedies, provided it be given in doses sufficient to produce its characteristic operation. For the purpose the hypodermic injection of atropine is to be preferred, and when the paroxysm occurs regularly its approach may be prevented by this remedy. The inhalation of an atomized preparation of belladonna may also be used. It is not without utility in spasmodic and membranous *croup*, and even in *laryngismus stridulus*, by moderating the laryngeal spasm. The *nervous vomiting* of pregnancy may be palliated by the internal use of the drug or by rubbing a solution of the extract upon the epigastrium. In *tetanus* the medicine has occasionally produced a cure, and also in cases of poisoning by *strychnia*, and in others of *epilepsy*, especially in children. It forms a valuable addition to the bromides in cases of epilepsy that resist the use of the latter alone.

The supposed power of belladonna to limit the amount of blood in the spinal cord has been invoked with apparent advantage in the treatment of *epidemic meningitis*. As it was given along with ergot, to which the same operation is attributed, the share of the former medicine in the cure is difficult to determine. These two medicines were originally associated in the treatment of *paraplegia* due to myelitis, ergot being at first administered alone, after which belladonna was given internally and applied in a plaster to the spine. Subsequently, iodide of potassium was prescribed in addition to the other remedies. It is a question, What was the value of the elements time and rest in this method of treatment?

One of the most useful applications of belladonna is the treatment by it of *incontinence of urine*, an affection presenting neither evident spasm nor pain, but in which probably the former state exists. By blunting the organic sensibility of the neck of the bladder it allays the spasm of this part, and prevents a call of nature until a due amount of urine has accumulated. The power of belladonna in dilating the pupil is most valuable in permitting a thorough exploration of the interior of the *eye* by means of the ophthalmoscope or otherwise, in obviating the unnatural adhesions which are so apt to occur in *iritis*, and also in preventing or in remedying prolapse of the *iris*. It was first applied to facilitate the operation for *cataract* in 1795. It is probable that the medicine lessens the congestive process in the eye by diminishing the calibre of the blood-vessels and by lowering the sensibility of the retina to light. Both locally and internally it is one of the most efficient remedies for *photophobia*. Where the eye is concerned the action of belladonna may be obtained by smearing its extract, softened with water, around the orbit, but the use of atropine is both more cleanly and more efficient. The dryness of the skin produced by belladonna has been proved clinically to render it an

efficient remedy for all forms of passive *perspiration*. The hectic sweats of phthisis, of profuse suppuration, of articular rheumatism, are all more or less under its control, and local and unilateral sweats have been arrested by its topical application. It is curious that in some cases the suspension of the cutaneous exhalation was followed by a compensatory diarrhoea. The requisite dose for checking perspiration is one that will produce a commencing dilatation of the pupil and a very slight dryness of the throat. A similar control over excessive *salivation* has been exerted by this medicine when the symptom in question followed hemiplegia. The control of belladonna over the *mammary secretion* has long been known, and liniments containing it have been used for drying up the milk or for diminishing it when excessive. It should be applied before inflammation has set in. It does not appear to be secreted with the milk. The stimulant action of belladonna upon the heart has been taken advantage of in *typhoid fever*. Under its use the pulse and temperature rather decline. Dr. Harley says: "My own impression is, that the stimulant action of belladonna on the heart is converted in the pyrexial state into a tonic, and, if not pushed too far, even a sedative, influence on the heart and blood-vessels generally; in other words, that it is a tonic and sedative to the sympathetic system generally. By this action the capillary circulation is accelerated, the contraction of the vessels promoted, and the arterial tension which attends congestion of the parenchymatous organs is relieved, and a load at once removed from the heart." There is reason to think that in some cases of cardiac *dropsy*, with feeble action of the heart through valvular obstruction or muscular degeneration, belladonna may be serviceable. In several instances also it appears to have rescued patients from fatal *collapse* (in endocarditis, diarrhoea, bronchitis) by sustaining the heart's action (Weber). The protective power of belladonna against the contagion of *scarlatina* has been both firmly maintained and vehemently denied. A careful examination of the evidence bearing upon the question has led us to the conclusion that so long as persons are under the influence of belladonna, as indicated by the state of the pupils, the throat, and the skin, the liability to contract scarlatina is very much diminished. Nor does there seem to be wanting a good reason why it should be so, since the mucous membrane of the throat and larynx is maintained by the drug in a condition unfavorable to absorbing the scarlatinous or any other morbid element that enters the body through these channels.

The *antagonism* of belladonna and opium has long been known and practically tested in cases of poisoning by the one or the other of those agents. Doubtless their antidotal action was suggested by their opposite actions upon the pupil. More recent observations have shown other points of opposition, thus: opium tends to produce coma, belladonna cerebral excitement; opium diminishes the internal and increases the cutaneous secretions, while belladonna increases the secretions of the gastro-intestinal tract and diminishes those of the skin; opium lessens the secretion of urine, but belladonna augments it; and, above all, opium exerts a depressing action upon the lungs and heart, but the functions of these organs are stimulated by belladonna. These opposite actions of the two medicines may surely be described by the single word antagonism, and neither experiments upon animals, however numerous, nor any amount of reasoning, however ingenious, can diminish its significance or its importance. Harley has shown, experimentally, that by removing the restraint due to partial collapse of the lungs, and by direct stimulation also, belladonna relieves the distended heart; and clinical observation demonstrates that this special stimulant operation is the very one that is needed to preserve life in opium-poisoning. Indeed, electricity, the cold dash, coffee, and other agents employed with success to combat the effects of opium can have no other mode of action. Every one who has witnessed the use of electricity or of flagellation in the successful treatment of opium-narcotism must have been convinced that these agents stimulate the lungs and heart, and so preserve life until the excess of the poison is eliminated or destroyed. It is evident that belladonna and its preparations can act in no other manner; and indeed clinical observation proves it, for unless the condition of the patient is such as to allow him to be impressed by the physiological antidote, it can do no good; and, on the other hand, unless the dose of the antidote is such as to attain, without exceeding, the due degree of stimulation, it may do serious harm. It results from experience that repeated and small doses of belladonna or of its alkaloid (from one-sixtieth to one-fortieth of a grain (Gm. 0.0010–0.0016) of the latter, hypodermically, is preferable) should be administered until the pulse and respiration acquire more force and the pupil begins to be dilated, but care must be taken not to substitute the narcotic action of belladonna for that of opium. By observing these rules a great many cases of opium-poisoning have terminated favorably which without treatment would probably have ended fatally.

Although poisoning by *physostigma* (Calabar bean) is uncommon, it should be known that belladonna (in the form of atropine) is the appropriate antidote for its effects. Its administration should be conducted upon the principles just set forth, and the guide for its dose and the frequency of its administration are to be found also in the dilating effect produced upon the contracted pupil.

Administration.—1 grain (Gm. 0.06) is the primary dose of the powder of belladonna, root or leaf. It should be gradually increased until the pupil begins to be affected. An infusion may be made with 20 grains (Gm. 1.30) of the leaves in half a pint of water, of which the dose is half a fluidounce every four or five hours. The tincture, fluid extract, and alcoholic extract, and atropine, are more frequently prescribed than belladonna in substance. For external use the ointment and plaster, and various liniments containing these preparations, are employed.

ATROPA MANDRAGORA, or mandrake, which has such a resemblance to *A. belladonna* as to call for some notice here, is chiefly interesting from its anæsthetic virtues. It was fully described in the first century of our era by Dioscorides, and after him by Pliny, and their descriptions were handed down by the Arabians to modern times. Of these writers, the first particularly mentions that wine of mandrake was administered to persons about to suffer amputation or the actual cautery. He speaks also of its juice being used in a suppository to induce sleep, and states that the fruit of the plant, and even the emanations from it, have the same effect. Indeed, he describes two species, but attributes the same qualities to them both. In 1848, Sylvester drew attention to the ancient uses of this plant as an anæsthetic. For many centuries, said Dr. Richardson (1873), *Atropa mandragora* was employed as a general anæsthetic, and the poets and historians, not less than the physicians, descanted on its potent efficacy. He experimented with a watery infusion preserved by alcohol. The effects produced in animals were dilatation of the pupils, paralysis of motion and sensation, excitement during the stage of recovery, or sleep and paralysis if the dose was too potent. Pigeons were affected by a very much smaller dose than rabbits. Death occurred by failure of the respiratory power from obstruction of the air-passages with accumulated secretions. The heart continued beating long after respiration had ceased. The muscles retained their electric excitability as much as an hour after death. In man, the tincture applied to the tongue produced a sensation of numbness lasting for several minutes, and an acid taste and dryness of several days' duration. In doses not sufficient to cause actual narcotism the symptoms induced were—desire for sleep, a sense of fulness in the vessels of the head, a peculiar enlarged and confused vision, an exaggeration of sounds, an inaction of the bowels, with white hard feces when the bowels were made to act, and a restless, nervous excitability closely akin to hysteria. The symptoms were not actually removed for 2 days, and left a lingering uneasiness and coldness still longer. These statements, when originally published, do not appear to have led to any further experiments with the drug, and we may repeat the remark of Dr. Francis Adams, made more than thirty years ago, that "we see no good reason why its well-regulated use might not be revived."

BENZINUM, U. S.—BENZIN.

Benzinum petrolei, P. G.; *Æther petrolei*.—*Petroleum benzin*, *Petroleum ether*, E.; *Benzine*, *Esprit* (*Naphthé*, *Éther*) *de pétrole*, *Pétroléine*, Fr.; *Petroleumbenzin*, *Petroläther*, *Benzin*, G. —

Preparation.—The lower hydrocarbons present in American petroleum are separated from the heavier compounds by fractional distillation and from all the lightest hydrocarbons by fractional condensation. (See PETROLEUM.)

Purification.—The disagreeable odor of crude benzin is to a considerable extent removed by agitation with sulphuric acid. Fairthorne (1880) recommended quicklime for the purpose, which removes the peculiar sulphurous odor. Grazer (1883) obtained the best results with a mixture of solution of potassium bichromate and sulphuric acid. The adhering acid is removed by washing.

Properties.—Benzin is a transparent, colorless, diffusive liquid of a strong, characteristic odor slightly resembling that of petroleum, but much less disagreeable; neutral in reaction; insoluble in water, soluble in about 6 parts of alcohol, and readily so in ether, chloroform, benzol, and fixed and volatile oils. It is highly inflammable, and its vapor, when mixed with air and ignited, explodes violently. It has a sp. gr. from 0.670 to 0.675 (0.640 to 0.670, P. G.), and boils at 50° to 60° C. (122° to 140° F.) (55° to 75° C. =

131° to 167° F. *P. G.*). Benzin should be carefully kept in well-stopped bottles or cans, in a cool place, remote from lights or fire.—*U. S.*

Constituents.—*Pentane*, C_5H_{12} , boils at 38° C. (100.4° F.), *hexane*, C_6H_{14} , at 70° C. (158° F.). The benzin of the *U. S. P.* should therefore consist chiefly of the former, while that of *P. G.* consists mainly of hexane, with variable quantities of pentane and *heptane*, C_7H_{16} , the latter boiling at 98° C. (208.4° F.); this also agrees with the density, which is for pentane .60, for hexane .63, and for heptane .71.

Tests.—Benzin when evaporated upon the hand should leave no odor, and when evaporated in a warm dish should leave no residue (absence of heavy hydrocarbons). When boiled a few minutes with one-fourth its volume of spirit of ammonia and a few drops of test solution of nitrate of silver, the ammoniacal liquid should not turn brown (absence of pyrogenous products and sulphur compounds), and it should require 6 parts of official alcohol to dissolve it (difference from benzol). If 5 drops are added to a mixture of 40 drops of sulphuric acid with 10 drops of nitric acid in a test-tube, the liquid warmed and set aside for half an hour, and then diluted in a shallow dish with twice its volume of water, it should not have the bitter-almond-like odor of nitro-benzol (absence of benzol).—*U. S.* On agitating 2 parts of benzin with a cold mixture of 1 part of sulphuric acid and 4 parts of fuming nitric acid, the liquid should not become colored, and should not acquire a bitter-almond-like odor.—*P. G.* Benzol being much higher in price than benzin, an adulteration of the latter with the former is not likely to occur; but these tests are useful for distinguishing the two liquids. (See also BENZOLUM.)

Pharmaceutical Uses.—Benzin is directed in the preparation of *Charta sinapis*, *U. S.*, for depriving powdered mustard-seed of fat. It may be used for the extraction of fixed oils, and has been recommended by Dr. Wolff for the preparation of volatile oils. It is employed in the arts as a solvent for fats, for caoutchouc, and for certain resins.

Physiological Action and Medical Uses.—According to Husemann, the vapors of benzol are destructive to insects, but pigs tolerate very large doses of it; *e. g.* 3 or 4 drachms. According to Gabalda, the poisonous action of benzin differs from that of nitrobenzin only in degree. It produces confusion of the senses, vertigo, unconsciousness, convulsions, coma, or sometimes only a sort of intoxication, like that of alcohol. As much as 50 drops have been given to *trichina* patients without injury, but the continued use of the oil produces some of the effects just mentioned, and without mitigating the disease. It has been employed locally in the treatment of *scabies*, but, although it destroys the itch-insects, it does not affect their eggs. It has also been used in *herpes tonsurans*, *furus*, *syccosis*, etc. Like creasote and carbolic acid, it restrains fermentation in certain forms of *dyspepsia*. As a substitute for the emanations from gas-works it has been used by inhalation in *whooping cough*. The ordinary dose is from 10 to 15 drops (*Gm.* 0.60–1.00). It may be prescribed in emulsion or, preferably, in capsules.

BENZOLIN.—SPICE-BUSH.

Wild allspice, *Fever-bush*, *E.*; *Laurier benzoïn*, *Fr.*; *Benzoeloorbeer*, *G.*

The bark and fruit of Benzoin odoriferum, *Nees*, s. *Lindera* (*Laurus*, *Linneé*) Benzoin, *Meissner*.

Nat. Ord.—*Lauraceæ*.

Origin.—The spice-bush is a shrub about 10 to 15 feet (3 to 4.5 M.) high, common in damp woods of Canada and the United States. It has deciduous oblong-obovate, entire, and smooth leaves, and produces in March and April lateral clusters of four or five yellow inconspicuous flowers.

Description.—1. THE BARK is in thin quills or curved pieces, yellowish or pale-brown and smooth upon the inner surface, and blackish-brown, minutely dotted with corky warts, somewhat glossy and nearly smooth, upon the outer surface. It breaks with a short granular fracture, has an agreeable though not very strong odor, and an aromatic somewhat pungent and astringent taste. Older bark has a brown-gray or dark-ash color and more prominent corky warts.

2. THE FRUIT is an obovate or oblong drupe, with a circular depressed scar of the pedicel, almost $\frac{3}{8}$ inch (9 Mm.) long, red, after drying blackish and granular upon the surface, and contains a single large white seed, with plano-convex cotyledons and having an oily taste. The fragile integuments of the fruit have a spicy taste, and when bruised an agreeable odor.

Constituents.—The bark was analyzed by J. Morris Jones (1873); it contains

some tannin, fat, starch, sugar, tasteless resin, and volatile oil, which, on being treated with oxidizing agents, develops the odor of bitter almonds, and belongs to the cinnamyl series. The air-dried bark yields 3 per cent. of ash. P. M. Gleim (1875) obtained from the berries, by treatment with petroleum benzin, 44 per cent. of a deep-red very aromatic oily liquid which is soluble in ether and chloroform and partly soluble in alcohol, glycerin, and oil of turpentine. The fresh berries yielded by distillation 5 per cent. of a colorless volatile oil having the specific gravity .87, and a fragrance somewhat like that of jessamine. A. W. Miller (1878) obtained 50 per cent. of greenish-brown oily and resinous constituents, and 1 per cent. of a thin light-green volatile oil having the specific gravity .850 and a warm aromatic taste, resembling that of allspice and prickly ash.

Medical Action and Uses.—The virtues of this plant, which depend upon its volatile oil, are those of a vascular stimulant and diaphoretic. As such it has been used in the forming stage of acute *pulmonary inflammations* and *rheumatism*, and in chronic forms of the latter affection. It has also been employed as a *vermifuge*. The bark has been used in *intermittent fever*. During the Revolutionary War the berries are said to have been employed as a substitute for allspice, and in the late Civil War a similar use was made of them in the Southern States. The oil has served as an ingredient of embrocations for rheumatism, *contusions*, and other local painful affections, and internally to relieve *flatulent colic*. It has also been applied in *scabies*. The bark and the berries are usually administered in decoction; the oil may be prescribed in alcoholic solution or suspended in water by magnesia.

BENZOINUM, U. S., Br.—BENZOIN.

Benzoe, P. G.; *Resina benzoe*, *Asa dulcis*.—*Gum benjamin*, E.; *Benjoin*, Fr.; *Benzoe*, G.

A balsamic resin obtained from *Styrax Benzoïn*, *Dryander*. *Philos. Trans.*, vol. lxxvii. plate 12; Bentley and Trimen, *Med. Plants*, 169.

Nat. Ord.—*Styracææ*.

Origin.—The tree yielding benzoïn is of medium height, has a hard dense wood, large branches forming a beautiful crown, a handsome dark-green underneath white hairy foliage, and reddish or white flowers in axillary racemes. It is indigenous to Borneo, Java, and Sumatra, and probably also to Cochin China and Siam, though it is not unlikely that the benzoïn coming from the latter country may be produced by a different species.

Collection.—The tree is cultivated in Sumatra to a considerable extent, but benzoïn is also obtained from wild trees. When about six or seven years old the trunks are about as many inches in diameter, and incisions are then made through the bark, when a white liquid resin commences to exude slowly; when sufficiently hard this is scraped from the bark. During the first three years the resin contains a large number of white tears, and is then called by the Malays *head benzoïn*. During the next seven or eight years the white tears decrease in number, and the product is termed *belly benzoïn*. At the expiration of this time the exudation is considerably diminished, the tree cut down, and an inferior quality, called *foot benzoïn*, scraped from the wood.

Siam benzoïn is likewise collected from incisions, but the tree yielding it is not known.

Commerce.—At the ports of Sumatra benzoïn is received in the form of cakes wrapped in matting, and after having been softened by heat is packed in chests and sent to Penang and Singapore, whence it finds its way into general commerce. In Siam benzoïn is carried on bullocks' backs to the Menam River, and then shipped to Bangkok, whence it is exported to other countries. In the year 1866-67, 5827 pounds of benzoïn were imported into the United States. In the recent statistical reports benzoïn is enumerated with other resins and gum-resins.

Description.—Sumatra benzoïn is met with in commerce usually in the form of large rectangular blocks, which consist of milk-white opaque tears, varying in size and frequently quite small, always agglutinated by a brown-gray resin. In the interior it is often porous, presents a mere mottled or variegated but no distinct, amygdaloid appearance. It has an agreeable odor, distinct from and weaker than that of Siam benzoïn. The tears melt at 85° C. (185° F.), the grayish-brown portion at 95° C. (203° F.) (*Pharmacographia*). It is always mixed with fragments of bark, of which the inferior kinds almost exclusively consist.

Penang benzoin is usually identical with Sumatra benzoin, but occasionally it differs from it in color, and more so in odor, which then suggests that of storax.

Siam benzoin has mostly a similar appearance, the inferior varieties consisting mainly of a grayish-red resin, which upon a fresh fracture is brown-red, glossy, translucent, and mottled with lighter spots, but containing few or no tears. The better quality is distinctly amygdaloid in appearance, on account of the milk-white tears, which are up to $\frac{1}{2}$ inch (12 Mm.) and more in diameter. The resin is often porous, and crystals of benzoic acid are observed in the cavities. In the finest amygdaloid variety the tears largely preponderate over the red-brown translucent resin, which is nearly entirely absent in the *benzoin in tears*. This variety is met with in separate or loosely-agglutinated, roundish, or flattened pieces, 1 or sometimes 2 inches (25 to 50 Mm.) in diameter, which are of a reddish-yellow color externally, internally white or striped, and melt at 75° C. (167° F.). The odor of Siam benzoin is pleasantly balsamic, somewhat like that of vanilla.

Impurities, consisting of fragments of wood, bark, etc., are present to a larger or smaller extent in all varieties of cake benzoin, and remain behind on treatment with alcohol. With the exception of these impurities, benzoin should dissolve in five times its weight of alcohol; this solution gives with water a milky liquid having an acid reaction.—*P. G.* The tincture of Siam benzoin has a distinct red color; that of the other varieties is more of a brown or yellowish-brown color; rendered milky by the addition of water, the peculiar fragrance of the different varieties is best perceived.

Constituents.—Benzoin contains several resins, a trace of volatile oil, and from 12 to 20 per cent. of benzoic acid. In addition to these, Siam benzoin contains vanillin, which was obtained by Rump (1878) from the mother-liquor of benzoic acid prepared by Scheele's process (see page 35) by agitating it with ether and evaporating. Kolbe and Lautemann (1860) found in Siam and Penang benzoin also cinnamic acid, and the same acid was observed in Sumatra benzoin by Aschoff (1861). The quantity of cinnamic acid varies considerably, and it is often altogether absent. The cause of its presence has not been ascertained. The white tears often contain less benzoic acid than the resin. This portion consists of about four resins, which dissolve partly in ether, but are alike, or nearly so, in their composition and behavior to alcohol, in which they are soluble, and to caustic potassa; by treating them with fused potassa, paraoxybenzoic acid, $C_7H_6O_3$, and protocatechuic acid are obtained, besides products of secondary decomposition.

Tests.—When benzoin is boiled with milk of lime the hot filtrate should not give off the odor of oil of bitter almond on the addition of test solution of permanganate of potassium (absence of cinnamic acid).—*U. S.* For determining the presence of cinnamic acid the tincture of benzoin may be precipitated by hot water, filtered from the resin, and the filtrate treated with a solution of potassium permanganate or chlorinated lime; or the benzoin may be triturated with peroxide of lead and the mixture boiled with water.

Off. Prep.—Acidum benzoicum, *Br.*; Adeps benzoïnatus, *U. S.*; *Br.*; Tinct. benzoini, *U. S.*; Tinct. benzoini comp., *U. S.*, *Br.*

Physiological Action and Medical Uses.—The internal action of benzoin has been considered in connection with benzoic acid, upon whose presence the virtues of the balsam chiefly depend; but the resin and volatile oil which it also contains communicate to it other qualities which assimilate it with the resins in general. Like these, it is a general and local stimulant, tending to elimination by the mucous membranes. This fact accounts for its established reputation in the treatment of chronic *bronchitis*, chronic *diarrhœa*, and *dysentery*. In the first of these affections the compound tincture of benzoin, or Turlington's balsam, has long been famous, and no medicine of its class excels it. Locally, the tincture is a most excellent stimulant and protective for wounds. The dose is stated to be from 10 to 40 grains (Gm. 0.60–2.60), but benzoin is never administered in substance.

BENZOLUM.—BENZOL.

Benzene, E.; *Benzole*, *Benzène*, Fr.; *Benzol*, *Benzen*, G.

Formula C_6H_6 . Molecular weight 78.

Preparation.—Benzol is obtained by the dry distillation of benzoic acid mixed with excess of lime, and by agitating the oily distillate with potassa solution and rectifying. It is largely obtained from *coal-tar*, one of the secondary products of the coal-gas manufacture; on subjecting it to distillation, water and ammonia pass over, accompanied by a brown oily liquid (8 or 10 per cent. of the tar), known as *light oil*, because it floats

on water. Subsequently *dead oil* is obtained as an oily liquid heavier than water, and containing aniline, quinoline, naphthalin, carbolic acid, etc.; the residue in the retort constitutes pitch, and is used in place of asphaltum. The light oil contains mainly *benzol*, *toluol* (C_7H_8), *xytol* (C_8H_{10}), and *isocumol* (C_9H_{12}), and after rectification to free it from some dead oil is known in commerce as *coal-naphtha*, which owes most of its disagreeable odor to volatile bases removable by agitation with dilute sulphuric acid. The hydrocarbons are separated from one another by repeated fractional distillation until liquids of a nearly constant boiling-point are obtained. The fraction boiling near $80^\circ C.$ ($176^\circ F.$) consists chiefly of benzol, that with the boiling-point $110^\circ C.$ ($230^\circ F.$) of toluol, that distilling near $140^\circ C.$ ($284^\circ F.$) of xytol, and the portion coming over near $170^\circ C.$ ($338^\circ F.$) of isocumol. The benzol may be further purified by exposing it to a low temperature and expressing the portion remaining liquid.

Properties.—At the ordinary temperature benzol is a thin, colorless, very inflammable liquid, of considerable refractive power and a strong odor of coal-gas; but when obtained from benzoic acid it has a peculiar aromatic odor and a sweetish aromatic taste. It has the density .899 at $0^\circ C.$ ($32^\circ F.$) and .878 at $15^\circ C.$ ($59^\circ F.$), congeals at the freezing-point of water, melts again at $5.5^\circ C.$ ($42^\circ F.$), and boils at $80.5^\circ C.$ ($177^\circ F.$). It is nearly insoluble in water, but readily soluble in 4 parts of alcohol, in methylic alcohol, ether, and acetone; it dissolves some phosphorus, sulphur, and iodine, and considerable quantities of fats, volatile oils, caoutchouc, gutta-percha, and some resins. W. Smith and G. W. Davis (1882) obtained a colorless crystalline compound with antimony trichloride, having the composition $3SbCl_3 \cdot 2C_6H_6$, and on exposure becoming opaque and liquefying. The name *benzin* was formerly given and is still used to some extent for benzol, but is best discarded as a synonym for the latter.

Composition.—Benzol is the hydride of phenyl, HC_6H_5 ; the hydrate of the same radical, C_6H_5HO , is carbolic acid.

Tests.—To distinguish it readily from *petroleum benzin*, Pusch (1875) recommends iodine, which dissolves in the latter with a raspberry-red and in benzol with a violet-red color; the former color is so intense that a small admixture of benzin can be recognized by neutralizing the violet tint. Commercial benzol obtained from coal-tar always contains variable quantities of the hydrocarbons mentioned above; it should boil and evaporate completely between 80° and $85^\circ C.$ (176° and $185^\circ F.$). Agitated with sulphuric acid, it should not acquire a dark color.

Pharmaceutical Uses.—Benzol is useful as a solvent for some alkaloids and the substances mentioned above, but is chiefly employed in the manufacture of NITROBENZOL and ANILINE (which see).

BERBERIS.—BARBERRY-BARK.

Cortex radicis berberidis.—Écorce de racine de berbérède (épine-vinette, vinettier). Fr.: Berberitzen- (Saurach-, Sauerdorn-) Wurzelrinde, G.

The bark of the root of *Berberis vulgaris*, *Linné*. Bentley and Trimen, *Med. Plants*, 16. *Nat. Ord.*—Berberidaceæ.

Origin.—The barberry is a shrub 6 to 8 feet (1.8 to 2.4 M.) high, with three-parted spines, fascicles of obovate-spatulate and bristly serrulate leaves, yellow flowers in pendulous racemes, and oblong one-celled scarlet berries of an acidulous taste. It is indigenous to Western Asia and the greater part of Europe, and has been naturalized in thickets and waste grounds in New England and other parts of North America. The bark of the root is the part mostly used in North America, while in Europe the entire root is usually employed.

Description.—The thick and branching root has a tough wood of a pale lemon-yellow color, distinctly porous from the rather large vessels, which are arranged in concentric circles and with plainly-visible medullary rays. The rather thin bark is found in small irregular pieces, is externally of a yellowish-gray, and upon the nearly smooth inner surface of an orange-yellow color; the corky layer is soft, and the deep-yellow bast-fibres are in tangential rows imbedded in a yellow parenchyma which is striate by medullary rays. The nearly inodorous bark has a strongly bitter taste, and imparts to the saliva a yellow color; its infusion does not yield a black precipitate with ferric salts.

Constituents.—According to the analysis of Pollex (1836), barberry-bark contains berberine, oxyacanthine, some starch, and tannin producing dark-green precipitates with iron salts, besides the usual constituents of vegetables.

Berberine, or *berberia*, was first discovered by Chevallier and Pelletan (1826) in the

bark of *Xanthoxylum clavæ Herculis*, *Linne*, and named *xanthopierit*; its identity with berberine was proved by Perrins (1862). A. Buchner obtained it (1835) crystallized from barberry-root, believed it to possess acid properties, and named it berberin. It had been previously separated in an impure condition by Brandes (1825) and by Buchner (1830). G. Kemp (1841) noticed that it forms crystallizable compounds with various mineral and organic acids, but its alkaloidal nature was first proven by Fleitmann (1846). Since then it has been discovered in numerous plants of the orders Berberidaceæ, Ranunculaceæ, Menispermaceæ, etc. (See papers in *Am. Jour. of Pharm.*, 1863, pp. 97, 301, and 456.)

For the preparation of berberine Procter (1864) gives a process which is based upon those of Buchner and Fleitmann: The root of hydrastis is exhausted with boiling water, the decoction evaporated, the soft extract exhausted by strong alcohol, some water is added, most of the alcohol distilled off, and then an excess of sulphuric acid added, when, on cooling, sulphate of berberine crystallizes, requiring recrystallization from hot water for purification. Its solution in hot water is then decomposed by freshly-precipitated oxide of lead (caustic baryta, Fleitmann) and the filtrate allowed to crystallize. It forms fine yellow needles, which lose at 100° C. (212° F.) nearly 19.5 per cent. of water, fuse at 120° C. (248° F.), are insoluble in ether, petroleum benzin, and carbon disulphide, and dissolve slightly in cold water and benzol and more freely in alcohol and alkalies. Its composition is $C_{20}H_{17}NO_4$ (Perrins). By adding to its hot solution an excess of acid crystals of neutral or acid salts are obtained, which are usually of a bright or golden-yellow color, have a bitter taste, and are very slightly soluble in acidulated water. Berberine dissolves in strong sulphuric acid with a dingy olive-green, and in nitric acid with a dark brown-red, color. Solutions of its salts are precipitated greenish-brown by potassium ferrocyanide, and yellow by picric acid, phosphomolybdic acid, or chloride of gold, platinum, or mercury; the precipitates are mostly crystalline or crystallize readily; the phosphomolybdate dissolves in ammonia with a blue color. Dissolved in hot alcohol, the salts of berberine yield, with solution of iodine in potassium iodide, dark-green scales of a metallic lustre and appearing reddish-brown in transmitted light; if an excess of iodine be employed, the crystals are of a red-brown color in reflected light. This behavior is recommended by Perrins as a convenient test for this alkaloid. Hydrochlorate of berberine assumes with chlorine a blood-red color (Buchner). This behavior furnishes a delicate test, by means of which, according to Klunge (1875), berberine may be detected in over 200,000 parts of solution; brucine, which gives a similar color with chlorine, yields with acids colorless solutions. L. Henry ascertained (1859) that berberine and its salts are colored blood-red by bromine, and that after the deposition of hydrobromate the solution gives a black precipitate with ammonia. Fused with potassium hydrate, berberine is decomposed, yielding two acids, one of which is sublimable, and vapors having the odor of chinolin (Hlasiwetz and Gilm).

Oxyacanthine, $C_{32}H_{46}N_2O_{11}$, remains in the mother-liquor from which the berberine salt has been precipitated by an acid. To avoid confusion with principles in *Crategus Oxyacantha*, Berzelius proposed to call it *berbine*, and Wacker suggested the name of *vinetine*. It is a white alkaloid, turning yellow in sunlight, nearly insoluble in water, and has a bitter taste and an alkaline reaction; it dissolves in 30 parts of cold and in 1 part of boiling alcohol, in 125 parts of cold and 4 parts of boiling ether, and is easily soluble in chloroform, benzol, fats, and volatile oils. It reduces iodic acid. Sulphuric acid colors it brown-red, the color changing on heating to bright-red and brown. Nitric acid imparts a yellow and, when heated, a purple color. Its salts give white precipitates with alkalies, soluble in excess, with alkali carbonates, potassium iodide, potassium ferrocyanide, potassium sulphocyanide, or mercuric chloride, and yellow precipitates with picric acid or potassium ferriocyanide.

These alkaloids are also contained in the wood and, according to Lenssen (1870), in the flowers; the latter contain, in addition, volatile oil, and 3.57 per cent. of sugar and 6.62 per cent. of malic acid were found in the berries.

Allied Species.—In India the root-bark of *BERBERIS ARISTATA*, *De Candolle*, *B. ASIATICA*, *Roosburgh*, and *B. LYCIUM*, *Royle*, is employed as a tonic; it contains berberine in abundance.

Several species of *Berberis*, belonging to the section *Mahonia*, are indigenous to the Pacific coast of North America, growing as far north as Vancouver Island, and are known as *Oregon grape*. *BERBERIS REPENS*, *Lindley*, is about 8 or 10 inches (20 to 25 Cm.) high; *B. AQUIFOLIUM*, *Pursh*, attains a height of 4 to 6 feet (1.2 to 1.8 M.), and *B. NERVOSA*, *Pursh*, of about 4 inches (10 Cm.). The rhizomes and roots of these low shrubs resemble each other closely, those of the first species being thinnest. Oregon grape-root varies in size from that of a quill to an inch

or two (3 to 25 or 50 Mm.) in diameter, is more or less knotty and crooked, has externally a yellowish-brown color, and is internally of a brighter yellow; the bark is thin, the wood tough, yellow, striate with fine medullary rays, and encloses a distinct pith. The bark has a bitter taste, and as obtained from *B. nervosa* was found by P. Neppach (1870) to contain berberine.

Physiological Action.—This bark, or that of an allied species, has long been employed in India as a tonic and febrifuge. Its virtues appear to depend upon berberine, which has also been found in several other medicines used as bitter tonics, and which was administered hypodermically to rabbits by Falck and Guenste. But the effects produced were not uniform. In one experiment they observed depression, paralysis, convulsions, and resolution, followed by death; in a second, in addition to such symptoms, profuse salivation, hurried and shallow breathing, anesthesia, etc., but the animal recovered; in a third case no sensible results were produced. Nearly 50 grains given to a dog in divided doses caused no definite effects, but a strong solution of muriate of berberine injected into the veins occasioned salivation, diarrhoea, convulsions, paralysis, and tremulousness, which last symptom continued for some time after the other phenomena had disappeared. The elaborate inferences drawn by Curci from his experiments have no apparent relation to those just stated (*Bull. de therap.*, c. 329). According to him, berberine, when locally applied, causes obstruction of the superficial vessels, and when injected subcutaneously it produces hyperemia and oedema of the surrounding tissues, followed by their induration. Internally, it coagulates the mucus and tonifies the coats of the alimentary canal. Thrown into the blood-vessels, it occasions debility, languor, somnolence, coldness, and finally death in collapse. At first it quickens the pulse-rate and the arterial pressure, while it lowers the bodily temperature. It renders the alkaline urine of herbivorous animals acid, and is eliminated mainly by the kidneys. Under its prolonged action animals lose weight, and their mode of death is by gradual extinction, and neither its phenomena nor the appearances after death are characteristic. It seems to retard the decomposition of the blood, and especially the separation of its hæmoglobin, and causes an enlargement rather than a contraction of the spleen. It is evident that these qualities, unless perhaps its alleged action on the capillary circulation, in no degree explain the virtues which have been attributed to berberine. In man, doses of 15 or 20 grains have occasioned some diarrhoea with or without colic. Small doses, on the other hand, appeared to increase the appetite and confine the bowels.

Medical Uses.—Berberine is supposed to act as a stomachic tonic and to increase the secretion of bile. It has been given in atonic *dyspepsia*, and especially in that condition following cholera, in *diarrhoea* from the same cause, in infantile and tuberculous diarrhoea, etc. In a word, it seems to be adapted to such cases as are usually treated with calumba. It has also been used with alleged success in reducing the *spleen* enlarged by malarial poisoning. It may be given in doses of from 2 to 5 grains (Grm. 0.10–0.30), in pill or powder or in alcoholic solution. *Berberis aquifolium* is said to be used in the Western States as a tonic and febrifuge.

BETULA.—BIRCH.

Bouleau, Fr.; *Birke*, Gr.

The bark, leaves, and saccharine juice of different species of *Betula*.

Nat. Ord.—Betulaceæ.

Origin.—This genus comprises shrubs and trees which are indigenous to the northern hemisphere, have alternate simple and straight-veined leaves, drooping staminate catkins, and shorter cylindrical fertile catkins, producing broadly-winged nutlets. The young twigs and leaves of most species are pungently aromatic; the bark is more or less completely separable into thin concentric layers, and when wounded in the spring exudes a juice having a sweet and somewhat acidulous taste.

Description and Constituents.—*BETULA ALBA*, *Linne*, is a slender and graceful tree indigenous to Northern Asia, Europe, and America, in the latter continent as far south as Pennsylvania. There are several varieties, varying in height from 15 to 75 feet (4.5 to 22.5 M.). The bark of the branches is brownish and verrucose, of the trunk white, smooth, separating in thin sheets, and of an astringent somewhat bitterish taste. The leaves are triangular-deltoid, acuminate, doubly serrate, light-green, shining, and of an astringent taste; when young, glandular and pungent. The buds and young twigs yield by distillation $\frac{1}{2}$ per cent. of a colorless *volatile oil* having a balsamic and pungent odor, and by the dry distillation of the wood and bark dark red-brown *birch-tar* or *daggett* is obtained, which

has a strong and persistent odor of Russia leather, and yields on distillation brown-red *empyreumatic oil of birch*, known as *oleum rusci*. The bark contains also a camphoraceous body, *betulin*, $C_{36}H_{60}O_3$, which forms light, flocculent, crystalline, tasteless masses fusible at about 258°C . (496°F .), subliming when heated with care, and soluble in ether, volatile oils, hot alcohol, and alkalis. On oxidation one or more acids are obtained, and on dry distillation an oily body, which, according to Hausmann (1878), has the characteristic odor of Russia leather. The whitish powder covering the young shoots and leaves is *betulo-resinic acid*, $C_{36}H_{26}O_5$, which, according to Kosmann (1854), has a bitter taste in alcoholic solution and dissolves in sulphuric acid with a red color.

BETULA PAPIRACEA. *Aiton*, the *canoe birch*, grows in Canada and the northern part of the United States, has ovate, heart-shaped, taper-pointed leaves, and a tough white bark splitting into thin papery layers, which are used by the Indians in making canoes.

BETULA LENTA. *Linne*, Sweet, black or cherry-birch. It is indigenous to Canada and the northern part of the United States, but grows in the mountains as far south as Georgia; has oblong heart-shaped and acuminate leaves, which are pubescent on the veins beneath, and a glossy brown bark, the outer layers of which are slightly laminate and the inner layers close and reddish-brown. The bark and leaves yield a volatile oil, which Procter (1843) found to be identical with oil of *gaultheria*, and which Kennedy showed (1882) is largely sold in place of the latter. Pettigrew (1883) found it to be pure methyl salicylate, and to have the spec. grav. 1.180 at 15°C ., and the boiling-point to be constant at 218°C . (424.4°F .). It does not pre-exist in the plant, but is formed by the action of water and an unknown compound of the bark upon *gaultherin*. This principle is syrupy, colorless, soluble in alcohol and water, insoluble in ether, and when distilled with sulphuric or hydrochloric acid yields the volatile oil. The bark contains 3.3 per cent. of tannin (Bowman, 1869).

Medical Action and Uses.—White birch is a popular remedy in the north of Europe. The sap is held to be a purifier of the blood, and is in general use for the cure of scaly diseases of the *skin*, *rheumatic* and *gouty* disorders, chronic affections of the *bladder*, *scurvy*, and *intermittent fever*. The fresh leaves are used to form a bed in which rheumatic patients lie, and which excites profuse sweating. Reduced to a pulp and mixed with gunpowder and cream, the bark is thought to be a sovereign remedy for the *itch*. A similar pulp mixed with oil is reputed to be efficient in discussing *scrofulous* enlargements of the glands. The oil of birch is likewise employed to cure chronic *cutaneous eruptions*, and is taken internally for the relief of *gonorrhoea*. It is said to have a more unpleasant odor than kindred oils, and when used should be scented with oil of rosemary or lavender. The American species (sweet birch) also appears to possess stimulant qualities; the bark and leaves are sometimes used to prepare diaphoretic infusions.

BIDENS.—SPANISH NEEDLES.

The herb of *Bidens bipinnata*, *Linne*.

Nat. Ord.—Compositæ, Senecionideæ.

Description.—This annual smooth weed is indigenous to the United States, and attains a height of about 3 feet (90 Cm.). The stem is quadrangular; the leaves are opposite, broadly ovate in outline, bipinnately dissected, the divisions lanceolate, mostly wedge-shaped at the base; the flower-heads are small, on long peduncles, have a double involucre, three or four short, yellow, and dark-veined ray-florets, and slender quadrangular three- or four-awned akenes. The plant has a disagreeable odor when rubbed, and a herbaceous afterward acrid taste. Its constituents have not been investigated.

Allied Species.—*BIDENS TRIPARTITA*, *Linne*—Chanvre aquatique, *F.*: Wasserhanf, *G.*—indigenous to Europe, has three-lobed serrate leaves, yellow tubular florets, and two-awned akenes. It was employed like the preceding. The same common names are applied in Europe to *BIDENS CERNUA*, *Linne*, Burmarigold, *E.*, which is also indigenous to Canada and the United States south to Virginia; it is known by its lanceolate, serrate, somewhat connate leaves, its nodding flower-heads with or without pale-yellow rays, and its flat, retrorsely-barbed, two-awned akenes.

Medical Uses.—There appears to be nothing to be added to the statement long ago made respecting this plant, that its roots and seeds have a popular reputation as *emmenagogues* and as remedies for acute *laryngeal* and *bronchial* affections; whence it may be inferred to be a stimulant and, when suitably administered with hot water, a diaphoretic.

BISMUTHI CITRAS.—CITRATE OF BISMUTH.

Bismuthum citricum, Citras bismuthicus.—*Citrate de bismuth, Fr.*; *Wismutheitrat, Citronsaures Wismuthoxyd, G.*

Formula $\text{BiC}_6\text{H}_5\text{O}_7$. Molecular weight 399.

Preparation.—Subnitrate of Bismuth 10 parts; Citric Acid 7 parts; Distilled Water a sufficient quantity. Boil the subnitrate of bismuth and the citric acid with 40 parts of distilled water, until a drop of the mixture yields a clear solution with water of ammonia. Then add 500 parts of distilled water, allow the suspended matter to deposit, wash the precipitate (first by decantation, and afterward on a strainer) with distilled water until the washings are tasteless, and dry the residue at a gentle heat.—*U. S.*

This is the process of R. Rother, first proposed in 1876, and consists simply in the decomposition at the boiling temperature of the bismuth subnitrate by the citric acid, anhydrous bismuthous citrate being formed, which is nearly insoluble in water and in the diluted nitric acid produced at the same time. The decomposition is ascertained to be complete by means of ammonia, which will then yield a clear solution with a drop of the turbid mixture. The yield is about $13\frac{1}{2}$ parts.

Properties and Tests.—Bismuth citrate is “a white, amorphous powder, permanent in the air, odorless and tasteless, insoluble in water or alcohol, but soluble in water of ammonia. When strongly heated the salt chars, and on ignition leaves a more or less blackened residue with a yellow surface, which is dissolved by warm nitric acid. This solution on being dropped into water occasions a white turbidity. The ammoniacal solution when treated with hydrosulphuric acid in excess yields a black precipitate. The filtrate, deprived by heat of the excess of hydrosulphuric acid and cooled, when boiled with lime-water produces a white precipitate; and when a portion of it is mixed with an equal volume of concentrated sulphuric acid and cooled, a brown or brownish-black zone should not appear around a crystal of ferrous sulphate dropped into the liquid (absence of nitrate).”—*U. S.*

Off. Prep.—Bismuthi et ammonii citras, *U. S.*

BISMUTHI ET AMMONII CITRAS, *U. S.*—CITRATE OF BISMUTH AND AMMONIUM.

Bismuthi ammonio-citras, Bismuthum citricum ammoniatum.—*Citrate de bismuth ammoniacal, Fr.*; *Wismuthammoncitrat, Citronsaures Wismuthammonium, G.*

Formula $(\text{NH}_4)_3\text{BiC}_6\text{H}_5\text{O}_7$. Molecular weight 504.

Preparation.—Citrate of Bismuth 10 parts; Water of Ammonia, Distilled Water, each a sufficient quantity. Mix the citrate of bismuth with 20 parts of distilled water to a smooth paste, and gradually add water of ammonia until the salt is dissolved and the liquid has a neutral or only faintly alkaline reaction. Then filter the solution, evaporate it to a syrupy consistence, and spread it on plates of glass, so that on drying the salt may be obtained in scales. Keep the product in small, well-stoppered vials, protected from light.—*U. S.*

Rother (1876) states that dry citrate of bismuth yields with ammonia-water a syrupy liquid and a hard white mass, the latter being unaffected by excess of ammonia, but dissolving on the application of a gentle heat; this solution crystallizes on cooling, and the crystals, after being dried on a water-bath, are again soluble in water, and may be regarded as a compound of triammonium citrate with bismuthous hydrate, having the formula given above. Since the Pharmacopœia makes no provision for supplying the ammonia lost during the concentration of the liquid, the salt will have a more or less variable composition, probably approaching that determined by N. Gray Bartlett (1865) for a salt prepared by a similar process—namely, $\text{BiC}_6\text{H}_5\text{O}_7 \cdot \text{NH}_4\text{HO} \cdot 2\text{H}_2\text{O}$ (molecular weight 470). The yield by Rother's process is nearly $12\frac{1}{2}$ parts, and by the official process $11\frac{1}{2}$ to 12 parts.

Properties.—Citrate of bismuth and ammonium is in “small, shining, pearly, or translucent scales, becoming opaque on exposure to air, odorless, having a slightly acidulous and metallic taste and a neutral or faintly alkaline reaction; very soluble in water and but sparingly soluble in alcohol. When strongly heated the salt melts, then chars, and finally leaves a more or less blackened residue with a yellow surface, which is dissolved by warm nitric acid. This solution, on being dropped into water, occasions a white turbidity. The aqueous solution of the salt, when boiled with solution of potassa, evolves vapor of ammonia, and when treated with hydrosulphuric acid yields a black precipitate. If the filtrate be deprived by heat of the excess of hydrosulphuric acid, and cooled, a por-

tion of it, boiled with lime-water, produces a white precipitate. Another portion, after being mixed with an equal volume of concentrated sulphuric acid and cooled, should not produce a brown or brownish-black zone around a crystal of ferrous sulphate dropped into the liquid (absence of nitrate).—*U. S.* The dry salt slowly loses ammonia on keeping, thereby becoming partly insoluble in water; the cautious addition of a few drops of ammonia-water to such a turbid mixture will then usually make a perfect solution.

Action and Uses.—If the virtues of subcarbonate and subnitrate of bismuth depend upon the insolubility of these salts, as appears to be the case, then their soluble salts must act in quite a different manner; but of their special action we possess no evidence. The *dose* of the nitrate of bismuth and ammonia is said to be 2 or 3 grains (Gm. 0.10–0.20).

BISMUTHI OXIDUM, *Br.* *Add.*—OXIDE OF BISMUTH.

Bismuthum oxydatum, Oxidum bismuthicum.—*Oxyde de bismuth, Fr.*; *Wismuthoxyd, G.*
Formula Bi_2O_3 . Molecular weight 468.

Preparation.—Take of Subnitrate of Bismuth 1 pound; solution of Soda 4 pints. Mix and boil for 5 minutes; then, having allowed the mixture to cool and the oxide to subside, decant the supernatant liquid, wash the precipitate thoroughly with distilled water, and finally dry the oxide by the heat of a water-bath.—*Br.*

In this process the subnitrate of bismuth is decomposed by the soda, nitrate of sodium and white bismuth hydroxide being formed, the former of which remains dissolved in the water; $2(\text{BiNO}_3 \cdot \text{H}_2\text{O}) + 2\text{NaHO}$ yields $2\text{Bi}(\text{HO})_3$ (or $\text{Bi}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$) + 2NaNO_3 . On drying the precipitate without heat it loses water and leaves *bismuthyl-hydroxide*, BiHO_2 ; but at the temperature of boiling water the anhydrous oxide is left.

Properties.—Oxide of bismuth forms a dull-yellow more or less crystalline powder, which dissolves in mineral acids without effervescence, and these solutions are colorless and yield black precipitates with hydrosulphuric acid, and white ones by alkalis, alkaline carbonates, and much water, the precipitates being insoluble in an excess of the precipitants. When heated to incipient redness the oxide is not diminished in weight. At a higher temperature it fuses to a brown mass, which becomes yellow again on cooling. The oxides of lead and silver are likely to be present as impurities, and are detected by dissolving in nitric acid and testing as described under BISMUTHI SUBNITRAS.

Action and Uses.—Oxide of bismuth would appear to be nearly insoluble in the stomach; for in a woman with gastric cancer, to whom it was given, a mass of it weighing a pound was found in the stomach after her death, which must have remained there for at least 2 months (*Practitioner*, xxviii, 293). It has been used for the same purposes as the subcarbonate and the subnitrate, and has been particularly recommended, when mixed with powdered acacia and muriate of morphia, as a snuff in *post-nasal catarrh* and *ozæna*. It may be prescribed in doses of 3 grains (Gm. 0.20) and upwards.

BISMUTHI SUBCARBONAS, *U. S.*—SUBCARBONATE OF BISMUTH.

Bismuthi carbonas, Br.; *Bismuthum subcarbonicum, Subcarbonas bismuthicus.*—*Carbonate of bismuth, E.*; *Sous-carbonate de bismuth, Fr.*; *Wismuthsubcarbonat, Basisches kohlen-saures Wismuthoxyd, G.*

Formula $(\text{BiO})_2\text{CO}_3 \cdot \text{H}_2\text{O}$. Molecular weight 530.

Preparation.—Take of Purified Bismuth in small pieces 2 ounces; Nitric Acid 4 fluidounces; Carbonate of Ammonia 6 ounces; Distilled Water a sufficiency. Mix the nitric acid with 3 ounces of distilled water, and add the bismuth in successive portions. When the effervescence has ceased, apply for 10 minutes a heat approaching that of ebullition, and afterward decant the solution from any insoluble matter that may be present. Evaporate the solution until it is reduced to 2 fluidounces, and add this in small quantities at a time to a cold filtered solution of the carbonate of ammonia in 2 pints of distilled water, constantly stirring the mixture as it is formed. Collect the precipitate on a calico filter, and wash it with distilled water until the washings pass tasteless. Remove now as much of the adhering water as can be separated from the precipitate by slight pressure with the hands, and finally dry the product at a temperature not exceeding 150° F. —*Br.*

In this process a solution of bismuthous nitrate is first formed and concentrated by evaporation, when it is added to a cold solution of an alkaline carbonate. Most metallic bismuth contains some arsenic, which is also oxidized by the nitric acid, so that arsenic of bismuth is found in the solution. In order to remove nearly the whole of the arsenic,

the nitric acid solution may be diluted with sufficient distilled water until it remains faintly milky after stirring; on being set aside for a day most of the arsenate will be found deposited as a white crystalline precipitate. The clear solution, still retaining a small proportion of arsenic, may be almost completely deprived of it by pouring it into an excess of ammonia-water, whereby soluble nitrate and arsenate of ammonium are formed, while bismuthous hydrate is precipitated; this may then be converted into subcarbonate by dissolving in sufficient nitric acid, pouring the liquid slowly and with constant stirring into a solution of sodium carbonate, draining the precipitate upon a strainer, and washing it with distilled water. This process was originally proposed by Dr. Squibb, and adopted in the U. S. P. 1870 with the following working quantities: Bismuth 2 troy-ounces is dissolved in a mixture of nitric acid $4\frac{1}{2}$ troyounces and water 4 fluidounces; the solution is diluted with water 10 fluidounces; on the next day decanted and filtered, diluted with water 4 pints, and mixed with ammonia-water 5 fluidounces; the precipitate is drained, washed, and dissolved in nitric acid 4 troyounces; the solution is mixed with water 4 fluidounces, next day filtered and slowly poured into a cold solution of sodium carbonate 10 troyounces in water 12 fluidounces; the precipitate is collected on a strainer, drained, and washed until the washings pass tasteless. In following this process it is important that the dilution with water should be carried far enough until a turbidity is observed which does not disappear completely on stirring; this solution should be set aside for a sufficient length of time, as indicated; the acid solutions should be added slowly and with continual stirring to the alkaline solutions, in order to ensure the complete decomposition of the acid salt; and the washing should not be continued for too long a time, in order to avoid gradual decomposition of the subcarbonate into hydrate. If the final precipitation be effected at a boiling temperature, an anhydrous subcarbonate would be precipitated.

The final reaction is explained by the equation $2(\text{BiONO}_3) + 3\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O} = (\text{BiO})_2\text{CO}_3 \cdot \text{H}_2\text{O} + 6\text{NaNO}_3 + 2\text{CO}_2$, showing that carbonic acid gas is given off.

Properties.—Bismuthous subcarbonate is a white or pale yellowish-white powder, permanent in the air, inodorous and tasteless, insoluble in water, alcohol, alkalies, and alkaline carbonates, but soluble with effervescence in nitric acid; at a red heat it is converted into yellow bismuthous oxide which is soluble in hydrochloric or nitric acid; and these solutions have the behavior described on page 326.

Tests.—On dissolving 1 part of the salt in 6 parts of warm nitric acid (sp. gr. 1.200) a copious effervescence takes place, and no residue should be left (absence of insoluble foreign salts). On pouring this solution into 50 parts of water a white precipitate is produced, and on filtering and concentrating the filtrate to 6 parts a portion of this, mixed with five times its volume of diluted sulphuric acid, should not become cloudy (absence of lead). If another portion be precipitated with an excess of water of ammonia, the supernatant liquid should not exhibit a blue tint (copper). On diluting a third portion with 5 volumes of distilled water the filtrate should remain unaffected by test solution of nitrate of silver (chloride) or of nitrate of barium (sulphate); also by hydrochloric acid (silver). If the salt be boiled with acetic acid diluted with an equal volume of water, and the cold filtrate freed from bismuth by hydrosulphuric acid, the new filtrate should leave no fixed residue on evaporation (alkalies and alkaline earths). On boiling 1 Gm. of the salt with 10 Ccm. of solution of soda (sp. gr. 1.260), and holding a glass rod dipped in acetic acid over the test-tube, not more than a faint white cloud, but no heavy white fumes, should appear (only traces of ammonia). If the preceding mixture, after thorough boiling, be diluted with water to 50 Ccm. and filtered, the filtrate, when supersaturated with hydrochloric acid and treated with hydrosulphuric acid, should not deposit more than a trace of a precipitate, which should not have a yellow or orange color (only traces of antimony, arsenic, tin). On boiling 1 Gm. of the salt with 10 Ccm. of strong solution of soda, decanting the liquid from the precipitated oxide of bismuth into a long test-tube, and adding about 0.5 Gm. of aluminium wire cut into small pieces (a loose plug of cotton being pushed a short distance down the tube), the generated gas should not impart any color or tint to paper wet with test solution of nitrate of silver and kept over the mouth of the test-tube for half an hour (absence of more than traces of arsenic).—*U. S.* On adding the powder to sulphuric acid, tinged blue with solution of indigo, the color of the latter is not discharged (absence of nitrate). Arsenic may be conveniently detected by the modifications of Fleitmann's test, described on page 28. When bismuth subcarbonate is heated to redness it gives off water and carbonic acid, and loses 9½ per cent. of its weight (*U. S.* 1870); anhydrous carbonate would lose 8.6 and the monohydrated 11.7 per cent. of weight.

Medical Action and Uses.—Introduced as a substitute for subnitrate of bismuth, this preparation was claimed to possess the advantages of greater solubility in the gastric juices, and therefore to be less likely than the subnitrate to confine the bowels and color the stools. But these effects should not be considered advantages, for they would unfit the salt more or less for being used in the class of cases in which the subnitrate has been found advantageous only because it is nearly insoluble. *Dose*, from 10 to 60 grains (Gm. 0.60–4.00), suspended in water.

BISMUTHI SUBNITRAS, U. S., Br.—SUBNITRATE OF BISMUTH.

Bismutum subnitricum, P. G.; *Bismuthum hydroico-nitricum*, *Magisterium bismuthi, Subazotas* (s. *Subnitras*) *bismuthicus*.—*Sous-azotate* (*Sous-nitrate*) *de bismuth*, Fr.; *Basisches Wismuthnitrat* (*salpetersaures Wismuthoxyd*), *Wismuthsubnitrat*, G.

Formula $\text{BiONO}_3 \cdot \text{H}_2\text{O}$. Molecular weight 306.

Preparation.—Take of Purified Bismuth in small pieces 2 ounces; Nitric Acid 4 fluidounces; Distilled Water a sufficiency. Mix the nitric acid with 3 ounces of distilled water, and add the bismuth in successive portions. When effervescence has ceased, apply for 10 minutes a heat approaching that of ebullition, and decant the solution from any insoluble matter that may be present. Evaporate the solution until it is reduced to 2 fluidounces, and pour it into half a gallon of distilled water. When the precipitate which forms has subsided, decant the supernatant liquid, add half a gallon of distilled water to the precipitate, stir them well together, and after 2 hours decant off the liquid, collect and drain the precipitate in a calico filter, press it with the hands, and dry it at a temperature not exceeding 150°F .—*Br*.

By dissolving the metal in nitric acid the latter is partly decomposed, nitrous acid vapors being evolved and water generated, while the bismuth dissolves, forming normal bismuthous nitrate; thus: $\text{Bi}_2 + 8\text{HNO}_3 = 2(\text{Bi}_3\text{NO}_3) + 2\text{NO} + 4\text{H}_2\text{O}$. Other metals likely to be present are dissolved with the formation of nitrates, except arsenic, which is oxidized to arsenic acid. The bismuth having been previously purified, the solution practically should contain only bismuthous nitrate. The latter requires now to be converted into the subnitrate, which is accomplished by water. The most uniform results are obtained by adding the acid solution to a definite quantity of cold water; the decomposition taking place may be explained by the following equation: $6(\text{Bi}_3\text{NO}_3) + 10\text{H}_2\text{O} = 5(\text{BiONO}_3 \cdot \text{H}_2\text{O}) + \text{Bi}_3\text{NO}_3 + 10\text{HNO}_3$. The nitric acid which is liberated will retain a portion of normal bismuthous nitrate in solution. Ditte ascertained that water containing in each liter 83 Gm. of $\text{N}_2\text{O}_5 = 96.83$ Gm. of HNO_3 will dissolve both normal and basic nitrate, forming with the latter the normal salt, so that no decomposition will take place on the further addition of the acid liquid. But if the precipitate is left for too long a time in contact with the acid mother-liquor, an oxynitrate of the formula $4\text{BiONO}_3 \cdot \text{BiH}_3\text{O}_3 \cdot 3\text{H}_2\text{O}$ is gradually formed; by precipitating the solution with water of about 50°C . (122°F .) an oxynitrate is obtained having the composition $5\text{BiONO}_3 \cdot \text{BiH}_3\text{O}_3 \cdot 3\text{H}_2\text{O}$; and by washing the official or the above compounds for some time with water they are decomposed into still more basic salts of the formulas $3\text{BiONO}_3 \cdot \text{BiH}_3\text{O}_3 \cdot 3\text{H}_2\text{O}$ and $3\text{BiONO}_3 \cdot 2\text{BiH}_3\text{O}_3 \cdot \text{H}_2\text{O}$. It is obvious from the foregoing that even with the most careful manipulation the product obtained is not likely to be of a definite composition, but to consist of a mixture of the above two salts or of intermediate basic salts.

The U. S. P. 1870 used commercial bismuth, which was freed from the contaminating metals by a process analogous to that described for the subcarbonate; the diluted and filtered solution in nitric acid was first precipitated by pouring it into an excess of solution of sodium carbonate; the bismuthous carbonate was redissolved in sufficient nitric acid, diluted with water, filtered, and poured into a definite quantity of water, to which subsequently ammonia was added to *partly* neutralize the nitric acid, so as to precipitate also the greater part of the bismuth still held in solution.

The following is an outline of the process of the German Pharmacopœia: Heat bismuth 2 parts and sodium nitrate 1 part to dull redness in an iron dish, stirring constantly until the metal has been finely divided; when partly cooled add water 5 parts and soda solution 3 parts, boil, filter, and wash the finely-divided metal and oxides; after drying dissolve in hot nitric acid 8 parts, heat to near 90°C . (194°F .), filter through asbestos from the precipitated bismuth arsenate, evaporate to 6 parts, and crystallize; wash the crystals 1 part with a little dilute nitric acid, triturate with water 4 parts; pour this mixture into 21 parts of boiling water, decant the liquid, drain the precipitate, and wash it with an equal bulk of water. The object of this process is to obtain the salt absolutely free from arsenic, nearly

the whole of which is removed as sodium arsenate in the first portion of the process, and the last traces by heating the acid liquid and crystallizing the normal nitrate, the crystals obtained under these conditions being free from this and other impurities.

The acid mother-liquor obtained in the above processes may be treated with an alkaline carbonate to recover the bismuth remaining in solution, and the deposits of bismuthous arsenate may be freed from the latter metal by boiling with excess of alkali, after which the undissolved portion may again be worked up for subnitrate.

With the view of obtaining the salt of definite composition, Lallieu (1878) proposed its preparation from the well-washed and still moist oxide obtained from 200 Gm. of the metal, by treating it with nitric acid equal to 48.5 Gm. of nitric anhydride, adding it in small quantities, and then heating until the mixture becomes limpid and white; after the addition of a little water the subnitrate is thrown upon a filter, washed with twice its bulk of water, expressed, and dried; the yield is 265 Gm.

Properties.—Subnitrate of bismuth is a heavy white powder in minute crystalline scales and of a somewhat satiny appearance. It is not altered on exposure to air or light, is inodorous, has a faintly acid taste, and when moistened on litmus-paper has a slight but decided acid reaction. It is insoluble in water and alcohol, but dissolves completely and without effervescence in mineral acids. "When heated to 120° C. (248° F.) it loses between 3 and 5 per cent. of moisture, and at a red heat it gives off yellowish-red vapors and leaves between 79 and 82 per cent. of yellow bismuthous oxide."—*P. G.* The formula given above requires 76.5 per cent. of Bi_2O_3 . This difference may be due to loss of water by drying at too high a temperature, but is usually owing to changes in its composition occurring during its preparation under the circumstances described above. The loss by ignition of these non-official oxynitrates ranges between 16 and 20 per cent.

Tests.—Bismuth subnitrate should dissolve in nitric acid without effervescence (absence of carbonate), and without leaving any residue (absence of insoluble matters), and this solution should yield no precipitate with dilute sulphuric acid, with solution of silver nitrate, or with barium nitrate (absence of lead, chlorides, and sulphates). When mixed with sulphuric acid diluted with an equal bulk of water it dissolves, and the solution acquires a black color on the addition of a crystal of ferrous sulphate (presence of nitrate). On treating this solution with an excess of ammonia and filtering from the white precipitate, the filtrate should not have a blue color (absence of copper), and should not give a precipitate with hydrosulphuric acid (absence of zinc). The sulphuric acid solution on being diluted with water and completely precipitated by hydrosulphuric acid should yield a filtrate which on being evaporated to dryness should not leave any residue (absence of alkaline, earthy, and certain metallic salts). Bismuth subnitrate on being heated with an excess of soda solution should not evolve any ammonia, and it should be entirely free from arsenic, so that a small portion of it when treated by Fleitmann's test (see page 28) produces no stain upon filtering-paper moistened with solution of silver nitrate.

Off. Prep.—Bismuthi oxidum, Trochisci bismuthi, *Br.*

Other Bismuth Salts.—1. BISMUTHI NITRAS S. TERNITRATE. BISMUTHUM TRIS-NITRICUM.—Bismuth nitrate, Normal bismuth nitrate, *E.*; Azotate (nitrate) de bismuth neutre, *F.*; Wismuthnitrat, *G.* $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$. Mol. weight 586.—The manner in which this salt may be obtained free from arsenic has been described above. Normal bismuth nitrate crystallizes in large colorless prisms having a strongly acid taste, melting at about 80° C. (176° F.) in its water of crystallization, parting with a portion of its acid near 120° C. (248° F.), and with the whole of it at 260° C. (500° F.), leaving Bi_2O_3 behind. Water decomposes the salt, forming a basic nitrate. Mr. Balmanno Squire (1876) found the normal bismuth nitrate to be soluble in glycerin, and this solution, when recently made, is miscible with water without being precipitated. Mr. J. Williams observed that heat must be avoided in preparing the solution and after diluting it with water, and that potassa and soda cause in it a white precipitate, which is dissolved by an excess of the alkali, the alkaline solution being miscible with water, but not with alcohol. Mr. W. W. Moorhead (1877) proposed a *glycerite of nitrate of bismuth*, using 2 troyounces of the crystals to sufficient glycerin to make 8 fluidounces. The salt may thus be prescribed in a perfect solution, which may be diluted by the patient when using it.

2. BISMUTHI OXYCHLORIDUM.—Bismuth oxychloride, Bismuthyl chloride, *E.*; Oxychlorure de bismuth, *Fr.*; Wismuthoxychlorid, *G.* BiOCl . Mol. weight 261.4.—It is prepared by slowly pouring a solution of bismuth in nitric acid into a solution of sodium chloride. It is a white powder known as *pearl white*, and in France, like bismuth subni-

trate, as *blanc de fard*. When heated in closed vessels it turns yellow and melts without decomposition, but on being heated in the air chlorine is given off and bismuthous oxide left. The salt is insoluble in water, but readily soluble in acid. It has occasionally been sold as oxide of bismuth.

3. BISMUTHI PHOSPHAS. Phosphate of bismuth is prepared by dissolving 5 parts of the subnitrate in sufficient nitric acid, and pouring this solution slowly into a solution of 6 parts of sodium phosphate. It is a white powder, resembling the preceding salt.

4. BISMUTHI LACTAS. Lactate of bismuth is prepared by boiling 10 parts of the subnitrate with an excess of caustic soda, washing the oxide well with water, and while still moist mixing it with 9 parts of lactic acid; the mixture is digested, and dried in the water-bath.

5. BISMUTHI SALICYLAS. Salicylate of bismuth is best prepared, according to Dr. L. Wolff (1883), by dissolving bismuth nitrate in glycerin and precipitating with a concentrated solution of sodium salicylate. It forms a granular powder having a pinkish tint, and is without action on test-paper; when heated it is decomposed, giving off a phenic odor, free from nitrous acid vapors.

6. BISMUTHI TANNAS, Bismuthum tannicum, Tannas bismuthicus.—Tannate of bismuth, *E.*; Tannate de bismuth, *Fr.*; Wismuthtannat, *G.*—44 parts of crystallized bismuthous nitrate are dissolved in the least possible quantity of nitric acid, previously diluted with half its weight of water; the solution is poured into an excess of solution of soda, the precipitate well washed with water, until the washings cease to have an alkaline reaction, and the moist precipitate triturated with 20 parts of tannin diluted with water, strained through muslin, and dried with the aid of a moderate heat. This is Cap's process, proposed in 1860; in the first part of it bismuthous hydrate is formed from the nitrate by decomposing it with sodium hydrate; the precipitate is then directly combined with tannic acid, with which it should be left in contact for an hour or two before being washed and dried. It forms a light-yellow powder which is insoluble in water and alcohol, and is entirely tasteless. When thoroughly dried its composition represents 53 per cent. of bismuthous oxide and 47 of tannin.

7. BISMUTHI VALERIANAS, Bismuthum valerianicum, Valerianas bismuthicus.—Valerianate of bismuth, *E.*; Valérianate de bismuth, *Fr.*; Wismuthvalerianat, *G.*—A solution of bismuthous nitrate in the smallest quantity of nitric acid, previously diluted with half its weight of water, is precipitated by a rather concentrated solution of sodium valerianate; the precipitate is washed with water, to which some valerianic acid has been added, until the washings, on evaporation, leave no residue, and afterward dried. Or 50 parts of subnitrate of bismuth are digested for 4 hours with 150 parts of ammonia diluted with the same weight of water; the sediment, consisting of bismuth hydrate, is well washed with water, drained, transferred to a mortar, and well triturated with 15 parts of concentrated valerianic acid, 30 parts of alcohol being gradually added during the trituration. It is afterward collected upon a filter and dried at the ordinary temperature. Prepared by either process, it is a white amorphous powder having a decided odor of valerianic acid, insoluble in water and alcohol, soluble in nitric and in sulphuric acid; the latter solution does not acquire a black color on the addition of ferrous sulphate (absence of nitrate). Other impurities may be detected by the same tests as in the bismuth subnitrate.

Physiological Action.—There is no doubt that, practically, subnitrate of bismuth is insoluble in the gastro-intestinal juices. Long ago, it is true, Orfila detected its presence in the liver, the spleen, and the urine, and his statements have been confirmed and extended by recent observations. Nevertheless, the quantity absorbed is quite inconsiderable, and there is nothing to show what the action is, if any, of that portion. Pure subnitrate of bismuth appears to act upon the stomach and bowels simply by coating their mucous membrane with a virtually insoluble and at the same time perfectly unirritating substance, which protects it against the action of the contents of these viscera, and at the same time probably restrains their secretions and absorbs the excess of free acids present. It may also decompose the sulphuretted hydrogen in these cavities. There is no doubt that it may be taken in unlimited doses without occasioning any signs of irritation whatever. When, as sometimes has happened in experiments on animals and in clinical experience, the medicine has produced all the effects of a corrosive poison, an examination of the specimen used has shown it to be adulterated with arsenic, or rather that the arsenic which is naturally associated with the bismuth has not been completely separated from it in the manufacture, or else that the preparation used was the nitrate, and not the subnitrate, of bismuth. In the case of a child ten months old and suffering from diarrhoea

about 400 grains of subnitrate of bismuth were administered in the course of 3 days. After the first week the child began to grow œdematous, the conjunctiva was injected, the tongue dry, and the pulse rapid. On chemical examination of the bismuth it was found to contain $\frac{2.0}{100}$ of 1 per cent. of arsenic acid, and the child had taken in all about $\frac{3}{5}$ gr. of this substance. On suspending the medicine the symptoms subsided (Underhill). It has also been shown that a minute proportion of oxide of lead may be found in subnitrate of bismuth. If so, its presence has never been betrayed by any special symptoms, notwithstanding the large doses habitually given of the salt. Patients using bismuth sometimes notice a peculiar alliaceous taste in the mouth, while a corresponding smell is exhaled by the breath. It has been attributed to the presence of tellurium, but there is no evidence to show that this metal would produce such an effect if it were present in bismuth preparations, which it is not. It has also been ascribed to the arsenic which they often do contain in a minute proportion. But not only does arsenic produce no such symptom in those who use it, but bismuth preparations arsenic free occasion this peculiar odor (Squibb). Pure subnitrate of bismuth occasions no morbid symptoms, but confines the bowels and blackens and deodorizes the feces. After death in persons who have been using it freely the gastric mucous membrane presents no peculiarities, but that of the small intestine is in parts bluish, and the colon and rectum are stained black by a reaction of the bismuth with the sulphurous compounds present.

Medical Uses.—Subnitrate of bismuth was originally employed to relieve certain chronic and painful affections of the stomach, which appear to have been *gastralgia* and *simple ulcer* of that organ. It is probable that the latter was the disease most commonly treated successfully, and that it was sometimes associated with neuralgia of the stomach. It is certain that pure *gastralgia* is not peculiarly benefited by bismuth, and that simple ulcer is signally improved by it. If the pain is greatest upon taking food, there is probably ulcer; if the paroxysms occur when the stomach is empty, they are probably neuralgic. Ulcerated *cancer* of the stomach is favorably influenced by subnitrate of bismuth, which, as in simple ulcer, forms a covering to the raw and irritable surface, and thereby lessens pain and vomiting. It is beneficial in cases of chronic *gastric catarrh* due to coarse food or excessive eating, and which are attended by a feverish condition, a coated tongue, and an enlargement of the papillæ. In almost every form of *diarrhœa* caused by irritation or ulceration of the intestinal coats this medicine is of the utmost service—in all cases, indeed, for which chalk has for a long time been employed. The premonitory *diarrhœa* of *cholera* is generally under its control when it is given in doses of not less than 30 or 40 grains, and the same is true of smaller doses in *cholera infantum*. There is no better agent for controlling the *diarrhœa* of *typhoid fever* when it becomes excessive at any period of the disease, but especially during its decline; and it is useful in *tuberculous diarrhœa*—provided that the doses of the medicine are large—and in all forms indeed of chronic *diarrhœa* and *chronic dysentery*. In *acute* as well as in chronic dysentery enemas composed of mucilage in which bismuth is suspended are very soothing to the inflamed and ulcerated bowel.

As a topical application subnitrate of bismuth is useful whenever a neutral protective and absorbent powder is required. Nothing is superior to it as an application to superficial abrasions and ulcerations, as in *intertrigo*, slight *burns*, confluent *variola*, *eczema*, *zoma*, *fissures of the anus*, *chapped nipples*, *lips*, and *hands*, and *leucorrhœa*. In the last-named disease powdered bismuth on a roll of charpie should be introduced into the vagina through a speculum, and withdrawn after 6 or 8 hours. *Cancerum oris* following an epidemic of measles was found to improve under the use of subnitrate of bismuth better than after any other topical measures (Macguire, *Med. Record*, xxiii. 113), showing the advantage of a protective treatment. A similar result is stated to have attended this method in the management of recent wounds (Riedel, *Am. Jour. Med. Sci.*, July, 1883, p. 250). It is an efficient remedy for acute *coryza* when repeatedly and thoroughly snuffed into the nostrils. Its efficacy may be increased by associating with it morphia and powdered gum-arabic; *e. g.* muriate of morphia gr. j., powdered gum-arabic 5j., subnitrate of bismuth 5iij. In chronic *coryza* the following powder has been strongly recommended as a snuff: subnitrate of bismuth 4 parts, liquorice-powder 8 parts, iodide of sulphur 30 parts. In most of these affections the cure will be hastened by associating with the bismuth oxide of zinc in the proportion of about one-fourth. In some cases of *scrofulous ozœna* cures have been effected by forcibly snuffing the finely-powdered subnitrate into the nostrils and daily cleansing the passages by means of the *douche*. Sometimes it is topically applied suspended in water, which appears to be irrational; and sometimes in glycerin, which is less so, since the glycerin, if pure, tends to deprive the tissues of their

moisture. The powdered salt is an efficient palliative of *fetid sweats* of the feet and other parts.

A modification of Böttger's test for *diabetic sugar* has been proposed by W. L. Dudley, as follows: "Dissolve subnitrate of bismuth in the least possible quantity of chemically pure nitric acid, and add to it an equal amount of acetic acid of ordinary strength; dilute to eight or ten times its volume, and filter if necessary. To the solution to be tested add sufficient sodium hydrate to render it strongly alkaline, then add a drop or two of the bismuth solution; heat to boiling, and continue the boiling for 20 or 30 seconds. If sugar is present, the white flocculent precipitate which is formed on the addition of the bismuth solution to the alkaline liquid will become gray or black" (*Amer. Chem. Jour.*, 1830). Loewe employs the following formula for the test solution: "Subnitrate of bismuth 15 Gm.; dissolve in pure glycerin 30 Gm.; solution of sodium hydrate (sp. gr. 1.34) 60 to 70 Cem., dilute with water 150 to 160 Cem.; heat to 212° F." (*Practitioner*, xxvi. 291).

The *dose* of subnitrate of bismuth varies from 3 to 4 grains (Gm. 0.20–0.25) in infantile cases to a teaspoonful for adults, but the average dose for adults may be stated at 10 grains (Gm. 0.60). It is best given with water alone and when the stomach is empty. Milk, soup, and similar liquids as vehicles tend to envelop the medicine, and to that extent neutralize its action.

PHOSPHATE OF BISMUTH has been proposed (by Tédénat) as superior to all the other bismuth compounds, because it is more insoluble than they are. It may be given in somewhat smaller doses than the subnitrate (*Bull. de thérap.*, xviii. 427).

SALICYLATE OF BISMUTH has been credited not only with moderating and curing, but even with aborting, *typhoid fever* (Huchard), but upon insufficient grounds. No doubt it moderates the diarrhoea and corrects the fetor of the stools in this disease, and if largely given may reduce the temperature and pulse-rate; but that it shortens the disease or lessens its mortality no proof exists.

TANNATE OF BISMUTH is astringent, and was at one time used internally in *diarrhoea* and topically in *gonorrhoea*, *leucorrhoea*, *ophthalmia*, etc. It is now very seldom employed.

There is no sufficient reason for believing that VALERIANATE OF BISMUTH is of the least therapeutical value.

BISMUTHUM, *Br.*—BISMUTH.

Bismuth, Fr.; *Wismuth*, G.

Symbol Bi. Atomicity trivalent and quivalent. Atomic weight 210.

Origin.—The supply of bismuth is chiefly derived from the mines in Saxony, where it exists in the metallic state associated with cobalt, nickel, and silver ores. It is likewise found oxidized as *bismuth ochre*, in combination with sulphur and with tellurium, and in gold ores. Deposits of bismuth ore have been discovered in Hungary, France, Cornwall, and other parts of Europe, in Texas, California, Mexico, Bolivia, and other parts of America, and in Australia. Bismuth appears to have been first recognized as a distinct metal by Basilius Valentinus in the fifteenth century, but was afterward frequently confounded with antimony, tin, and zinc until Pott (1739), and afterward Bergmann, Davy, and others, proved its distinct properties.

Preparation.—The metal is extracted by a simple process of smelting, advantage being taken of its low melting-point, and run into hot iron receiving-pots, where it congeals. The sulphide of bismuth requires to be roasted; it is thus converted into oxide, which is reduced to the metallic state by being heated with charcoal. The crude metal thus obtained contains variable quantities of arsenic, copper, iron, and other metals.

Purification.—BISMUTHUM PURIFICATUM. *Br.*—Purified bismuth. Take of Bismuth 10 ounces; Nitrate of Potash in powder 2 ounces. Put the bismuth and 1 ounce of the nitrate of potash into a crucible, and heat them to a temperature at which both the metal and the salt are fused. Continue the heat, constantly stirring the contents of the crucible for 15 minutes, or until the salt has solidified into a slag over the metal. Then remove the salt, add the remainder of the nitrate of potash to the bismuth in the crucible, and repeat the process as before. Finally, pour the bismuth, while fused, into a suitable mould, and allow it to cool.—*Br.* (For a similar process, in which sodium nitrate is used, see BISMUTHI SUBNITRAS.)

A method proposed by Mr. Méhu (1873) aims at the formation of an alloy with potassium by heating to redness a mixture of powdered crude bismuth, potassium carbonate, charcoal, and soap under a layer of well-washed charcoal; the metallic button obtained

at the end of an hour is then fused in a capsule, for the purpose of oxidizing the potassium to potassa, which is accomplished when a yellow-brown layer of bismuthous oxide begins to form. It is claimed that arsenic and sulphur are completely removed by this process.

Properties.—Bismuth is a brilliant grayish-white metal with a distinct roseate tinge and a crystalline lamellate texture. When fused bismuth is cooled until a crust has formed, and the liquid portion is then poured out, the crucible will be found lined with rhombohedral crystals resembling cubes. Its specific gravity is 9.83, which is diminished by high pressure. It fuses at 268.3° C. (515° F.), and when congealing expands considerably, like water under similar circumstances, the density of the liquid metal being more than 3 per cent. greater than that of solid bismuth. It boils above 1100° C. (2012° F.), and may be distilled in a current of hydrogen. It is superficially tarnished at the ordinary temperature by exposure to the air, but at a red heat decomposes the vapor of water and burns in the air with a bluish flame to brown oxide, becoming yellow on cooling. It has the peculiar property of lowering the fusing-point of metals; an alloy of 2 parts of bismuth and 1 part each of lead and tin fuses at 93.75° C. (200.75° F.) It is but slightly attacked by boiling hydrochloric or dilute sulphuric acid; but nitric acid dissolves it readily, the solution on concentrating yielding crystals of bismuthous nitrate (see BISMUTHI SUBNITRAS); the mother-liquor or the original solution in nitric acid, suitably diluted with water and separated from the white precipitate of subnitrate, should not yield a white precipitate with sulphuric acid (lead), or a blue one with potassium ferrocyanide (iron), or with the same reagent a reddish-brown one (copper). The presence of arsenic is ascertained by adding sulphuric acid to the solution, evaporating it to complete dryness, and applying Marsh's or Fleitmann's test (see pages 27 and 28). Silver, which is occasionally present, will be indicated by the white precipitate which takes place in the nitric acid solution, previously diluted with water as much as possible, on the addition of hydrochloric acid. The fetid breath following the administration of bismuth preparations has been attributed by C. Ekin (1876) to the presence of some tellurium; but from observations made by Dr. Squibb (1882) this appears to be doubtful, or at least not the sole cause.

The salts of bismuth are colorless, except those formed with a colored acid or acidulous radical. The nitrate, sulphate, and chloride dissolve in a small quantity of acidulated water, but are decomposed by a large quantity of water, with the formation of insoluble basic salts. The solutions of bismuth salts yield with hydrosulphuric acid a black precipitate insoluble in sulphhydrate of ammonium, with alkalies white precipitates insoluble in an excess, and with zinc, cadmium, or copper a dark-gray spongy mass consisting of metallic bismuth. The solutions give with potassium iodide a yellowish-brown precipitate, becoming red on the addition of water; this coloring being so intense that a minute quantity of bismuth may be detected in lead if the acetate is precipitated by an excess of potassium iodide and the mixture heated to boiling; on cooling, the golden-yellow color of the lead iodide will be tinged crimson, orange, or brown, according to the proportion of bismuth present (Field and Abel, 1877).

Off. Prep.—Bismuthi subcarbonas Bismuthi subnitrates, Br.

BISTORTA.—BISTORT.

Snakeweed, El.; *Bistorte*, *Couleuvrine*, Fr.; *Wiessenknöterich*, *Natterwurz*, G.

The rhizome of *Polygonum bistorta*, Linné. Woodville, t. 232; Bentley and Trimen, *Med. Plants*, 212.

Nat. Ord.—Polygonaceæ.

Origin.—Snakeweed is an herbaceous perennial which grows in swampy meadows throughout Asia north from the Himalayas, in the greater portion of Europe, in Canada, and in the mountainous regions of the Western United States from Colorado northward. Its simple stems bear alternate ovate leaves with long and striate sheaths, and a terminal cylindrical dense racemose spike of rose-colored flowers. The young shoots and leaves are used for greens in the north of England and in subarctic countries, and the roasted rhizome is eaten in Siberia and Iceland.

Description.—The rhizome, which is collected in spring or autumn, is bent twice upon itself, is flattish on one side, rounded upon the other, transversely furrowed or annulated from the leaf-sears, and marked with the sears of the rootlets. As found in commerce, its total length is about 2 inches (5 Cm.); it is about $\frac{1}{2}$ inch (12 Mm.) broad, about $\frac{1}{4}$ inch (6 Mm.) thick, and of a firm texture, though fleshy and somewhat spongy

when fresh. Externally it is blackish-brown, internally reddish or brownish-red, and shows upon the transverse section a moderately thick bark, a large central pith, and a circle of very small whitish wood-bundles. It is inodorous and has a strongly astringent taste.

Constituents.—Bistort contains much starch and tannin. Bowman (1869) found the latter to amount to 21 per cent. The rhizome is also said to contain gallic acid. *Extract of bistort*, prepared with diluted alcohol, is occasionally employed; the yield is about 12 per cent.

Allied Plants.—The herbs of most species of this genus have a slight astringent and more or less saline or acidulous taste, and have been occasionally employed as mild astringents. *Pol. Persicaria*, *Linné*, the *spotted knotweed* or *lady's thumb*, has the lanceolate leaves usually marked near the middle with a brown semilunar or triangular spot. *Pol. amphibium*, *Linné*, or *water-knotweed*, grows in ponds, swamps, and in damp sandy soil, is variable in appearance, and has the rose-red flowers in dense spikes. *Pol. hydropiperoides*, *Michaux*, or *mild water-pepper*, has narrow lanceolate leaves and slender spikes of whitish flowers. *Pol. aviculare*, *Linné*, known as *knot-grass*, *birdweed*, or *goose-grass*, is occasionally erect, but usually has the slender branches prostrate or ascending, and bears two to four inconspicuous greenish and reddish flowers in the axils of the small leaves.

The following, which are decidedly acrid, have elliptic or lanceolate pellucid-punctate leaves and more or less interrupted linear spikes of greenish and reddish flowers: *Pol. Hydropiper*, *Linné*, known as *water-pepper* or *smartweed*, has the leaves often dark-spotted and the akenes of a dull brown, flatish or obtusely triangular; *Pol. acre*, *Kunth*, has larger green leaves and acutely triangular glossy akenes. Dr. C. J. Rademaker (1871) isolated from water-pepper *polygonic acid*, upon which the medicinal properties mainly depend; it is green, crystallizable, soluble in alcohol, ether, and chloroform, almost insoluble in water, soluble in alkalis with a yellow color, and is precipitated by basic lead acetate, mercurous nitrate, and mercuric chloride.

Pol. acre and *Pol. hydropiperoides* are American plants; the remaining species are common in both hemispheres.

Medical Action and Uses.—In Europe this medicine is used for all the purposes of a simple and mild astringent, both internally and externally; *i. e.* in *diarrhœa*, passive *hæmorrhages*, *leucorrhœa*, relaxation of the *throat*, *anus*, *vagina*, etc. It may be prescribed in powder, decoction, or extract. The decoction is prepared with an ounce (Gm. 32) of bruised bistort to a pint of water. *Dose*, a tablespoonful every 2 hours.

BOLDUS.—BOLDO.

Boldo, Fr., G.

The leaves of *Peumus Boldus*, *Molina*, s. *Ruizia* (*Peumus*, *Persoon*, *Boldoa*, *C. Gay*) fragrans, *Ruiz and Pavon*. Bentley and Trimen, *Med. Plants*, 217.

Nat. Ord.—Monimiaceæ.

Origin.—Boldo- or boldu-leaves are derived from a tall evergreen dioecious shrub which is a native of Chili, and is there frequently cultivated in gardens. It has lax cymes of sweet-scented, apetalous, greenish-yellow flowers, the pistillate ones producing about three yellowish drupes of the size of a pea and containing a single albuminous seed. The bark is used in tanning and the wood is esteemed for charcoal-making.

Description.—The leaves are opposite, on short petioles, coriaceous, about 2 inches (5 Cm.) long, broadly oval or oval-oblong, very obtuse at the apex, entire or somewhat undulate on the margin, rough on both sides, glossy above and pale and hairy beneath. The dried leaves are often reddish-brown, and have a fragrant odor and a refreshing aromatic pungent taste.

Constituents.—Claude Verne (1875) obtained from the leaves 2 per cent. of volatile oil, which after rectification is yellow, colored hyacinth-red by sulphuric acid, violet by nitric acid, red by potassa, and is decolorized by hydrochloric acid; it is freely soluble in alcohol, commences to boil at 185° C. (365° F.), and contains no aldehyd. Boldo-leaves also contain about $\frac{1}{10}$ per cent. of the alkaloid *boldine*, discovered by Bourgoin and Verne (1873); it is best extracted with acetic acid, imparts to water a bitter taste, is soluble in

FIG. 40.

Bistorta: natural size.

alcohol, ether, chloroform, benzol, and caustic alkalis, and is colored red by nitric and sulphuric acids. Besides some tannin and aromatic resinous compounds the other constituents do not possess any medicinal importance.

FIG. 41.

Boldo-leaf, natural size.

Pharmaceutical Uses.—Verne has proposed a *tincture of boldo*, made with 20 parts of the leaves and 100 parts of 60 per cent. alcohol; *wine of boldo*, made with 3 parts of the leaves and 100 of Madeira wine; an *aqueous* and an *alcoholic extract of boldo*, the latter prepared by evaporating the tincture.

Allied Plants.—*Atherosperma moschata*, *Labillardière*, an Australian tree, known there as *sassafras tree*, has in all parts an odor resembling somewhat that of nutmeg; the bark, which is used as an antiscorbutic and tonic, contains tannin and the bitter alkaloid *atherospermine*, which is a white amorphous powder readily soluble in alcohol and chloroform, but dissolving sparingly in ether; its colorless solution in sulphuric acid becomes green with potassium chromate (Zeyer, 1861). The allied South American genera, *Citrosma* and *Laurellia*, are highly aromatic. The bark of these trees is used for tanning.

Physiological Action.—Like all plants which contain an essential oil, boldo in moderate doses is an active stimulant of the nervous and circulatory systems. In the experiments which have been made with it some of the effects produced are referable to the alcoholic vehicle. Thus, when it is said that 15 grains of the extract, dissolved in 14 Cem. of alcohol, were injected into a dog and the dose renewed at the end of an hour, when the animal could not stand on his legs and was sleepy, and his temperature had fallen a degree or two, it is evident that of these effects the greater part were due to the alcohol. The judgment is not essentially different when 30 grains of alcoholic extract of boldo were injected dissolved in 8 Cem. of alcohol. It is confirmed when we find that among the symptoms following the administration of the volatile oil to a large dog not one refers to the nervous system, but chiefly to the urine, which acquired a strong smell; to the stomach, which was disturbed by vomiting; and to the bowels, which were affected with diarrhœa. In man even the tincture is represented not to have produced cerebral or spinal phenomena, but only a glow in the mouth, fauces, and stomach, and some quickening of the pulse; and the oil, in the dose of 30 or 40 Cg., in capsules, caused some burning at the epigastrium, nausea, and eructation, which, as well as the smell of the urine, lasted for not less than 12 hours. In still larger doses only a higher degree occurred of the same phenomena, with the addition of diarrhœa. It is therefore an error to say, as has been done, that oil of boldo is a diffusible stimulant, resembling oil of turpentine in its action. Experiments upon himself by Verne (1882) showed that boldo affects neither the circulation, the temperature, nor the secretion of urine, but that it augments the discharge of urea (*Bull. de théér.*, cii. 286).

Medical Uses.—Boldo has been recommended, in alcoholic or vinous solution, for *anæmia*, *dyspepsia*, and *general debility*, and the oil has been proposed for the relief of *catarrh*, especially of the urino-genital organs. The tincture has been prescribed in doses of 5 to 15 drops (Gm. 0.30–1.00). It does not appear to have commended itself to general use.

ATHEROSPERMIA MOSCHATA. According to Graves (*Lancet*, Feb. 1, 1862, p. 134), under the name of “native sassafras” it has long been used by the early settlers and Bushmen of Australia for making a sort of diet-drink in *rheumatic* and secondary *syphilitic* affections. He used it in his own person in *chronic bronchitis*, and in less than 24 hours his pulse fell from 120 to 80, and the expectoration from being excessive and difficult became moderate and easy. Other physicians employed it with equal advantage, and subsequently administered the oil in drop-doses as a sedative of excessive and irregular action of the heart. A decoction made with an ounce of the bark to a pint of water and boiled for 10 or 15 minutes was administered every 3 or 4 hours in doses of an ounce or two.

BOLUS.—BOLE.

Bol, Fr.; *Bohus*, G.

Description.—This term is applied to certain native silicates of aluminium, which are soft and unctuous to the touch, readily adhere to the moist tongue, and are easily scraped with the knife; they break with a conchoidal fracture, are insoluble in water, with which they gradually form a pasty mass, do not effervesce with acids, and for

medicinal use are powdered and elutriated with water. They contain alumina and silica in the approximate proportion of 3 to 5. According to color they have been distinguished as—

BOLUS ALBA, P. G. known also as *Argilla* and *terra alba*; it is of a white color, and contains small quantities of magnesia and traces of iron.

BOLUS ARMENA, S. RUBRA, ARGILLA FERRUGINEA, or *Armenian bole*, was formerly brought from Armenia, but is at present obtained in different parts of Europe. Its brown-red color is due to the presence of a considerable proportion of ferric oxide. *Terra lemnia*, formerly employed, differed from it merely in being of a yellowish color and containing less iron. After having been formed into flattish circular pieces and impressed with a seal these boles constituted the *terræ sigillatæ* which were formerly in high repute.

CRETA RUBRA, RUBRICA FABRILIS, *red chalk* or *reddle*, is firmer than the preceding, contains more iron, and is used for marking on wood and stone.

Medical Action and Uses.—Bole was very generally used in Greek and Roman medicine, and in Europe until a quite recent date, in numberless cases requiring astringent and absorbent medicines. Of internal affections for which it was employed may be mentioned *menorrhagia*, *hæmoptysis*, *chronic bronchitis*, *diarrhœa*, and *dysentery*. Topically, it was applied in *leucorrhœa*, *prolapsus ani*, *sore nipples*, *aphthæ*, *intertrigo*, *burns*, *ulcers*, *erysipelas*, etc. The small proportion of iron contained in it may have increased its efficacy. *Dose*, 5 to 10 grains (Gm. 0.30–0.60).

BORAGO.—BORAGE.

Bourrache, Fr.; *Borasch*, *Boretsch*, G.

Borago officinalis, Linné.

Nat. Ord.—Boraginaceæ.

Description.—Borage is an erect hispid annual indigenous to the Levant, but naturalized in Southern and Middle Europe and frequently cultivated in gardens. It has a white fleshy root and an erect branching stem 1 or 2 feet (.3–.6 M.) high. The leaves are oval or obovate, alternate—the lower ones petiolate, entire, or wavy on the margin, the upper side and the veins beneath with stiff hairs. The flowers are in terminal racemes with ovate bracts, have a five-parted calyx, and a sky-blue or reddish corolla, which is rotate, closed in the throat by five emarginate appendages, and has five stamens. The fruit consists of four brownish-black ovate roughish nutlets, which are excavated at the base. The fresh plant has a slight cucumber-like odor and a saline taste. The herb is used as a salad and occasionally employed in medicine; the root and flowers have likewise been used.

Constituents.—Borage has been analyzed by Lampadius and Braconnot, who found considerable mucilage, a little resin, and potassium and calcium combined with organic and mineral acids. Braconnot obtained from the inspissated juice 30 per cent. of salts; Wailt (1829) from the dry herb 2 to 3 per cent. of potassium nitrate.

Allied Plants.—*CYNOGLOSSUM OFFICINALE*, Linné.—Hound's tongue, *E.*; *Langue de chien*, *Fr.*; *Hundszunge*, *G.*—A biennial European plant naturalized in North America. The stem is 2 feet (.6 M.) high; the leaves are hairy, elliptic, and petiolate, the upper ones lanceolate, sessile, and somewhat clasping; the flowers are brownish-red and have a short, white tube; the ovate nutlets are covered with short, hooked prickles. The fresh plant has a disagreeable odor; the taste is mucilaginous and slightly bitter.

PULMONARIA OFFICINALIS, Linné.—Lungwort, *E.*; *Pulmonaire*, *Fr.*; *Lungenkraut*, *G.*—A perennial European plant with a simple hairy stem and rough hairy entire leaves, often marked with white spots, and with reddish or purple nodding flowers. The radical leaves are ovate-cordate, pointed, and petiolate; the stem-leaves are spatulate or ovate, the upper ones sessile. The herb is inodorous, and has a mucilaginous somewhat astringent taste.

MERTENSIA (PULMONARIA, Linné) VIRGINICA, De Candolle.—Virginia lungwort, Cowslip, *E.*—It grows from New York westward, and southward to Texas, is a smooth herb 1 or 2 feet (.3 or .6 M.) high, and has obovate-oblong or elliptical sessile leaves, the lower ones narrowed into a petiole, and corymbose racemes of flowers, with a purple-blue or white corolla about an inch (25 Mm.) in length and four times as long as the calyx.

ECHINUM VULGARE, Linné.—Viper's bugloss, Blueweed, *E.*; *Vipérine*, *Fr.*; *Natterkopf*, *G.*—It is a common European perennial, and is naturalized in North America. It is rough-hairy, about 2 feet (.6 M.) high, and has linear-lanceolate leaves and showy blue flowers in axillary clusters, forming an elongated terminal raceme. It has very little odor and a mucilaginous taste. Both the herb and the long, nearly simple, brown, and internally white fleshy root have been employed.

Medical Action and Uses.—The virtues of borage, which are chiefly those of an emollient and protective, it owes to the mucilage it contains, while its saline elements render it somewhat diuretic when its infusion is freely used. In France especially it is much employed in acute *febrile* affections and in *pulmonary catarrhs*. The infusion is made with from 1 to 3 drachms (Gm. 4–12) in a pint of water. A decoction made from the whole plant and a fomentation prepared with the flowers are used in local inflammations.

Cynoglossum in a fresh state gives off an exhalation which has produced aero-narcotic effects, and the leaves are a popular remedy for superficial *burns, bruises, abrasions*, etc., and for glandular and other local swellings. *Pulmonaria* is a lenitive and expectorant, and its dried leaves are somewhat astringent. It is extensively used in France as an ingredient of tisanes for coughs in various pulmonary affections. Its name is, indeed, derived from such uses of the plant. *Mertensia* has similar properties, and *Echium vulgare* is, at the same time, diuretic by means of its potassium and other salts.

BRAYERA, U. S.—BRAYERA.

Kooso, Cusso, Br.; *Flores koso, P. G.*—*Kouso, Kusso, E.*; *Couso, Kouso, Fr.*; *Koso, Kusso, Cusso, G.*

The female inflorescence (flowers and tops, *Br.*) of *Brayera anthelmintica, Kunth, s. Banksia abyssinica, Bruce, s. Hagenia abyssinica, Willdenow.* Bentley and Trimen, *Med. Plants*, 102.

Nat. Ord.—Rosaceæ, Rosææ.

Origin.—This is a handsome tree, attaining a height of 40 to 60 feet (12 to 18 M.); it produces an abundance of large oddly pinnate leaves, at the base with a sheath formed

by the large adnate stipules; the inflorescence is abundant, axillary, unisexual, and paniculate. The tree, which flowers in October and November, is indigenous to the table-land and mountainous districts of Abyssinia, and is generally planted near towns and villages.

Description.—The panicles are about 12 inches (30 Cm.) long, much branched; axis and branches zigzag, hairy, and glandular, each branch supported by a ciliate sheathing bract; flowers very numerous, $\frac{1}{4}$ to $\frac{1}{2}$ inch (6 to 8 Mm.) broad, each with two large roundish membranous-veined bracts at the base, which are green in the staminate flowers, but become purplish-red in the pistillate flowers; calyx shortly stalked, top-shaped, hairy, and with ten membranous and veined segments arranged in two alternating whorls. The sepals of the outer whorl of the male flowers are greenish-yellow, small, and nearly linear; but in the female flowers they are finally about $\frac{2}{3}$ inch (10 Mm.) long, and much larger than the inner row of sepals, and when fully developed are obovate and of a red color. The five linear petals are inconspicuous and much shorter than the inner sepals, with which they alternate. Stamens between fifteen and thirty, very small and shrivelled in the female flowers, equalling the petals in the male flowers, inserted in the contracted throat of the calyx. Carpels two, or occasionally three, distinct, enclosed in the calyx-tube; styles projecting from the tube; fruit

FIG. 42.

Brayera anthelmintica, Kunth: A, lowest branch of panicle, $\frac{1}{2}$ size; B, staminate flower; C, section of pistillate flower; magn. 4 diameters.

a small membranous akene, pointed by the persistent short base of the style, and containing a straight fleshy embryo with two plano-convex cotyledons.

The female inflorescence being most frequently collected, the commercial article should have a pale brownish-red hue, and is often distinguished as *red kouso*. It is collected

before the fruit has ripened, and either the entire inflorescence is dried loosely, or before quite dry a number of panicles are formed into cylindrical rolls, measuring about 10 to 20 inches (25 to 50 Cm.) in length, weighing about 4 to 8 ounces (120 to 240 Gm.), and tied by split culms of *Cyperus articulatus*; the loose panicles are usually much broken. The male inflorescence has in the dry state a light greenish-brown color, and is sometimes known as *koussou-esels*. The odor of both varieties is not strong, but pleasant and tea-like; the taste is gradually developed, mucilaginous, bitterish, acrid, and disagreeable.

The drug reaches commerce mostly by way of Aden and Bombay, or partly through Egypt to Southern Europe. It should be kept in a dark and dry place. "For medicinal use the drug should be freed from the stalks."—*P. G.*

Constituents.—According to Wittstein (1840), koussou contains as principal constituents 6.25 per cent. of a bitter acrid resin and 24.4 per cent. of tannin, consisting of two kinds; he also obtained 15.71 per cent. of ashes and some tasteless resin, besides the common constituents, chlorophyll, wax, sugar, and gum. The acrid resin appears to be the medicinally active principle, and has been variously called *brayerin*, *kwosein*, *koussin*, and *kosin*. As prepared by Dr. C. Bedall (1872) by Pavesi's process, it was found to be an efficient tæniifuge. Koussou is repeatedly treated with alcohol to which slaked lime has been added; the residue is boiled with water, the different liquids mixed, filtered, and distilled, and the remaining liquid treated with acetic acid, which separates about 3 per cent. of koussin as a white flocculent precipitate, becoming denser and resin-like, and on drying yellowish or at a higher temperature brown; in larger quantities it has a peculiar odor of Russian leather, a persistent bitter and acrid taste, and is of a distinct crystalline appearance when viewed under the microscope. Dr. E. Merck has subsequently further purified it, probably by crystallizing it from boiling alcohol. Flückiger and E. Bury (1874) describe it as forming yellow rhombic crystals, which are readily soluble in benzol, bisulphide of carbon, chloroform, and ether, less freely in glacial acetic acid, sparingly in cold alcohol, and are insoluble in water; alkalies dissolve it readily, and acids precipitate it again; it fuses at 142° C. (287.6° F.), and congeals to a transparent yellow mass, which when touched with a trace of alcohol is converted into stellate tufts of crystals: its composition is $C_{31}H_{38}O_{10}$, and it is probably an ether of isobutyric acid. Prof. Buchheim found this *pure kosin* to be very inferior in its anthelmintic action.

By distillation with water, koussou yields traces of valerianic and acetic acids and a little solid volatile oil having the odor of the drug.

Off. Prep.—Extract. brayeræ fluid., Infus. brayeræ (cusso, *Br.*), *U. S.*

Medical Action and Uses.—Koussou has been employed from time immemorial in Abyssinia for the expulsion of tape-worms, which there prevail extensively. But it is stated by Johnson that the operation of it is so severe that it often produces miscarriages, and even death, in pregnant women. In Europe it is said sometimes to have occasioned severe colic, but generally its operation is not distressing, and consists only of slight nausea, followed by feculent and then by liquid stools. According to Arena, these differences depend upon an alteration which the resin undergoes by time. Of all the remedies for tape-worm (*Tænia solium*, *T. bothriocephalus*) none is more efficient or certain, provided that the flowers are fresh, but they deteriorate rapidly. The parasite is generally discharged dead.

The Abyssinian mode of using it is thus described: An infusion is made with water or beer, or the flowers are mixed with honey to the amount of from 4 to 6 drachms (Gm. 16–24), and the whole is taken in the morning, fasting, and no food is eaten during the day. Generally, the worm is discharged in the course of 24 hours without purging, pain, or colic. This description by Aubert and by Engleman contradicts the one given above. In Europe and in this country an infusion is prepared with 2 drachms (Gm. 8) of the powdered drug in 4 fluidounces (Gm. 128) of boiling water, which, when cold, is drunk without having been strained. Kraus recommends 25 Gm. (5vi) in lemonade on an empty stomach, and followed an hour later by castor oil. As its taste and smell are disagreeable, resembling somewhat those of senna tea, it has been proposed to administer the powder in granules made with sugar and swallowed with some aromatic infusion. The following mode of preparing the dose has been recommended: Treat by displacement $\frac{1}{2}$ ounce of koussou in powder with 6 drachms of boiling castor oil and 1½ ounces of boiling water. Express the liquid, and make an emulsion with it and the yolk of egg; add 40 drops of sulphuric ether, sweeten, and flavor with oil of anise. This emulsion should be taken, fasting, at one dose. In all cases the patient should fast the day before using the medicine.

BROMAL.—BROMAL HYDRATE.

Hydrate de bromal, F.; *Bromalhydrat*, G.

Formula $C_2HBr_3O.H_2O$. Molecular weight 298.4.

Preparation.—Bromal was discovered by Löwig (1832), and is obtained by leaving 1 part of ether or absolute alcohol and 3 parts of bromine in contact for several days, and distilling off about three-fourths, the distillate consisting of hydrobromic acid and various brominated compounds; the residue, dissolved in water, yields crystals of bromal hydrate, which require purification with sulphuric acid, rectification over lime, and recombination with water. Schäffer (1871) obtained better results, and with less bromine, by passing the latter in the gaseous state into alcohol, distilling, and collecting the portion coming over between 165° and 180° C. (329° and 356° F.), consisting chiefly of bromal and *bromoform*, which are separated by fractional distillation, the latter boiling at 152° C. (305.6° F.).

Properties.—Bromal is a colorless oily liquid boiling at about 172° C. (342° F.) and remaining liquid at -20° C. (-4° F.); it has a peculiar penetrating odor and a pungent burning taste; its vapors are irritating to the eyes. On exposure to a moist atmosphere it is converted into a white crystalline mass of *bromal hydrate*, which is obtained in larger transparent crystals from its solution in water; the hydrate has the odor and taste of bromal, fuses at 53.5° C. (128.3° F.), and when distilled is decomposed into water and bromal. The *alcoholate* fuses at 44° C. (111.2° F.), is slightly soluble in water, and decomposes by heat. Solution of potassa or soda decomposes bromal and its hydrate, forming formiate and bromoform, the latter having a sweet taste and an agreeable aromatic odor.

Tests for Purity.—A mixture of bromal hydrate and strong sulphuric acid separates oily bromal, but is not colored brown. The solution of bromal hydrate in distilled water is clear, and yields no precipitate with nitrate of silver.

Physiological Action and Medical Uses.—Bromal hydrate is a powerful and almost caustic irritant; applied to the skin in an ointment, it occasions redness and swelling, with subcutaneous infiltration, and therefore should not be used hypodermically. Unless greatly diluted it cannot be taken internally, and even then it soon gives rise to burning in the throat, vomiting, and diarrhœa. It has been tried in *epilepsy* ineffectually, and there is no reason why it should be used at all as a medicine.

BROMINI CHLORIDUM.—CHLORIDE OF BROMINE.

Chlorure de brôme, Fr.; *Chlorbrom*, G.

Preparation.—According to Balard, chlorine gas is conducted into bromine, and the vapors given off are condensed by the aid of a refrigerating mixture.

Properties.—It is a reddish-yellow, thin, and very volatile liquid, which is soluble in water and yields a hydrate fusible at 7° C. (44.6° F.). On treating the solution with potassa, chloride and bromate of potassium are formed; its composition is probably $BrCl_5$.

Physiological Action and Surgical Uses.—This powerful caustic has been chiefly known as the principal ingredient of Landolfi's paste, which about 1854 attracted considerable attention, in Germany especially, for the treatment of *cancer* and other recurrent growths. The man and his method were subjected to a critical examination, with the result of condemning the former as a charlatan and the latter as more mischievous than useful.

BROMUM, U. S., Br., P. G.—BROMINE.

Brominium, U. S. 1870.—*Brôme*, Fr.; *Brom*, G.

Symbol Br. Atomicity univalent. Atomic weight 79.8.

A liquid non-metallic element obtained from sea-water and from some saline springs.

Origin and Preparation.—Bromine was discovered by Balard (1826) in the mother-liquor obtained in the preparation of common salt from the water of the Mediterranean; he also investigated its chemical properties, and proved its close analogy to chlorine and iodine. Bromine does not exist in the free state, but is found widely distributed in nature, the bromides usually accompanying chlorides. It is more particularly found in sea-water, in the waters of Kreuznach, Kissingen, and other mineral springs, but is now obtained in considerable quantities from the mother-liquors of many salt-works in

the United States and at Stassfurth, Germany. These mother-liquors, which have been freed by crystallization as much as possible from other salts, chlorides and sulphates, contain the bromine, usually in combination with magnesium or calcium. These compounds are decomposed either by heating their solution with black oxide of manganese and hydrochloric acid, or by warming it to between 45° and 50° C. (113° and 122° F.) while chlorine gas is being passed into it; the bromides are at once decomposed; $\text{MgBr}_2 + \text{Cl}_2$ forms $\text{MgCl}_2 + \text{Br}_2$. The bromine volatilizes, and is condensed under a small quantity of water, which is contained in a deep Woulf's bottle kept cool by water, while that portion of bromine which escapes condensation is conducted into a solution of caustic potassa contained in an open bottle; this solution, when it has nearly lost its alkaline reaction, is subsequently utilized for the preparation of potassium bromide. The mother-liquors, as obtained in Western Pennsylvania and West Virginia, yield about $\frac{1}{2}$ per cent. of bromine, or the brine about 1 pound of bromine to 13 bushels of salt. The production of the Ohio and Kanawha valleys amounts to about 130,000 pounds of bromine annually, in addition to which from 800 to 1000 pounds are manufactured in Pennsylvania (S. S. Garrigues, 1873). According to Wellcome (1877), about 1000 pounds are daily manufactured in the United States.; W. J. M. Gordon (1883) gives the annual production in this country at between 450,000 and 500,000 pounds.

Properties.—It is a brownish-red mobile and very volatile liquid, exhaling at the ordinary temperature deep orange-red vapors, which are highly irritating to the eyes and lungs, and on being conducted into a flame impart to it a green color. Its odor, which is suggestive of chlorine and iodine, is suffocating and disagreeable, hence its name (from *βρωμος*, a stench). It boils at 63° C. (145.4° F.) (Pierre); Balard and others gave the boiling-point as low as 47° C. (117° F.). At 15° C. (59° F.) its specific gravity is 2.99, and at the freezing-point of water 3.187. It congeals at about -25° C. (-12° F.), at the same time increasing its volume about 6 per cent. It destroys cork, wood, etc., bleaches litmus and other coloring principles, and alters or destroys most odorous organic compounds. It dissolves in 33 parts of water at 15° C. (59° F.), and in less of alcohol and ether; the brown-red, or if diluted brown-yellow, solutions are bleached rapidly in the sunlight, hydrobromic acid being formed. Bromide of potassium increases the solubility of bromine in water. Carbon disulphide, benzol, and chloroform dissolve bromine freely with an orange-red color, and, like ether, take it up from the aqueous solution on being agitated with the latter. When in contact with water at a low temperature, bromine forms a deep-red hydrate, $\text{Br}_2 \cdot 10\text{H}_2\text{O}$, crystallizing in octahedrons or in scales, which at 15° C. (59° F.) are decomposed into bromine and water. Bromine and its solutions color starch-paste brown-yellow.

Impurities.—Iodine does not now often form an impurity of bromine, but chlorine is frequently present, and causes a lowering of the boiling-point. Bromide of carbon is occasionally present in crude bromine, and may be removed by careful rectification, its boiling-point being considerably higher than that of bromine.

Tests.—Bromine should completely volatilize by exposure to air or to heat (absence of salts, etc.). "If 3 Gm. of bromine be mixed with 30 Ccm. of water, and enough water of ammonia to render the solution colorless, the liquid then digested with carbonate of barium, filtered, evaporated to dryness, and the residue gently ignited, the latter should be soluble in absolute alcohol without leaving more than 0.26 Gm. of residue (absence of more than 3 per cent. of chlorine). If an aqueous solution of bromine be poured upon reduced iron and shaken with the latter until it has become nearly colorless, then filtered, mixed with gelatinized starch, and a few drops of bromine solution be now carefully poured on top, not more than a very faint blue zone should appear at the line of contact of the two liquids (limit of iodine)."—*U. S.* If an aqueous solution of bromine be agitated with an excess of powdered iron, the greenish liquid on the addition of a little ferric chloride and chloroform should not impart a violet color to the latter (absence of iodine).—*P. G.*

Pharmaceutical Uses.—In the manufacture of most of the medicinal bromine compounds free bromine is or may be employed; it is directed for *Ammonii bromidum* and *Potassii bromidum*, *Br*.

Bromine blocks for disinfecting purposes have been recommended by Frank (1882), and consist of a porous mass formed by incinerating a mixture of diatomaceous earth with crude tartar or with calcium saccharate; cut into cubes of 45 Ccm., these weigh about 30 Gm. and absorb 100 Gm. of bromine, which is very gradually given off on exposure.

Physiological Action.—When dogs are confined in an atmosphere of bromine vapor they suffer a profuse secretion from the eyes, nostrils, and fauces, with cough,

hoarseness, and dyspnoea. It is a corrosive irritant of the stomach, producing vomiting, pain, diarrhoea, and death by exhaustion. On dissection the mucous membrane of the stomach and bowels is found softened. Applied to the shaven hide, bromine acts as a caustic and produces gangrenous sores. As it is extremely volatile, care must be taken not to allow its vapors to reach the eyes, nostrils, or mouth.

Medical Uses.—Formerly, bromine was employed in the class of cases in which the use of iodine has become general—viz. glandular and other forms of *scrofula*, chronic diseases of the *skin*, constitutional *syphilis*, chronic enlargement of the internal *lymphatic* and *mesenteric glands*, the *liver*, *spleen*, *ovaries*, *uterus*, etc.—but in all of these uses it has been superseded by iodine. During the Civil War of the United States it was extensively used in the treatment of *hospital gangrene*, according to the method of Dr. Goldsmith, which consisted essentially of cleansing the wound as far as possible of gangrenous tissue, and then applying pure bromine by means of a cotton or lint swab attached to a long wooden handle. Lint moistened with a weak solution of bromine in water was then laid on, covered with oiled silk or other impermeable tissue, and secured with a bandage. After a few hours a poultice was substituted, under which the eschar separated, leaving a healthy wound. The operation was severe, and the patient while undergoing it was etherized. *Cancer* of different forms and of various external organs has been treated by tissue injections of a strong solution of bromine in alcohol, 1 part to 3; but owing either to its inefficiency or its painfulness the method does not appear to have been generally adopted. A weaker solution (1 part in 8) has been used with some advantage as a local application to the skin for the purpose of allaying *pain*.

Recently the topical use of bromine has been revived in the treatment of *diphtheria*. Miller claims almost uniform success from pencilling the affected parts of the fauces with a solution of equal parts of bromine and bromide of potassium (Gm. 0.5–0.10 = gr. 8–12) in Gm. 200 = f ʒvi of water. He also employs inhalations of bromine from a solution of 10 grains each of the two agents in from 10 to 15 ounces of water (*Centralblatt f. d. ges. Therap.*, i. 341).

BRYONIA, U. S.—BRYONIA.

Bryony, E.; *Couleuvrée*, F.; *Zaunrübe*, *Gichtrübe*, G.

The root of *Bryonia alba*, Linné, and *Br. dioica*, Linné.

Nat. Ord.—Cucurbitaceae.

Origin.—Both plants are climbing monœcious and diœcious perennials and indigenous to Europe, *Br. alba* being more frequent in the northern, and *Br. dioica* in the southern section of that continent. They have rough, cordate, five-lobed, and toothed alternate leaves, and cymes of four to six small greenish-yellow flowers. *Br. alba* has black. *Br. dioica* red, globular berries, which are $\frac{1}{4}$ inch (6 Mm.) in diameter; hence the names *black* and *red bryony*. The root is collected in spring, and on drying loses from 85 to 88 per cent. in weight.

Description.—The roots are 18 inches to 2 feet (45 to 60 Cm.) long and 2 to 4 inches (5 to 10 Cm.) thick, nearly simple, in the fresh state fleshy and somewhat lactescent. Both are externally pale grayish-brown, transversely wrinkled, the root of *Br. alba* with numerous transversely elongated suberous warts or ridges. Internally they are white, have a thin bark, a brown cambium line, broad medullary rays, and numerous small narrow wood-bundles arranged between the medullary rays in radiating lines, and concentrically in circles separated by rather broad circles of parenchyma. This latter tissue shrinks considerably in drying, and, the root being usually dried in transverse slices, these show an irregular radiating and concentric arrangement from the projecting wood-rays. Dried bryony-root is inodorous and has a disagreeable bitter taste.

Constituents.—The bitter principle *bryonin* appears to have been first obtained pure by Walz (1859), though Schwerdtfeger had previously separated pearly crystals of a bitter and acrid taste, which, however, contained nitrogen. The aqueous solution of the alcoholic extract is precipitated by subacetate of lead, the filtrate treated with sulphuretted hydrogen, neutralized with soda, and precipitated by tannin; this precipitate is dissolved in alcohol, the solution treated with lime, the filtrate decolorized with animal charcoal, evaporated, and washed with ether. Bryonin forms a white powder having the composition $C_{48}H_{80}O_{19}$, of an intensely bitter taste, insoluble in ether and soluble in water and alcohol. When boiled with dilute sulphuric acid, bryonin is split into glucose and amorphous *bryoretin* and *hydrobryoretin*, the former of which is soluble, and the latter insoluble.

ble in ether. Bryony-root contains also starch, gum, sugar, albumen, waxy and fatty matter, malates and other salts.

Off. Prep.—Tincture bryoniæ, *U. S.*

Allied Plants.—*BRYONIA AMERICANA*, *Lamarck*, and *BR. AFRICANA*, *Thunberg*, are employed in their native countries like European bryony. The former species is indigenous to the West Indies, the latter to Southern Africa.

BR. EPIGÆA, *Rottl.*, of India has a mucilaginous and slightly bitter root, which is used by the natives as an alterative in syphilis and as a remedy in snake-bites.

Tapuya-root of Brazil, which has been recently recommended as a remedy for syphilis and scrofula, is said to come from a species of *Bryonia*.

Physiological Action.—The powder, introduced into a wound in a dog's leg, caused the animal's death in 24 hours, with symptoms of great depression, the wound suppurating. Conveyed into the stomach of a similar animal and the œsophagus being tied, death occurred after about the same interval, and the mucous membrane of the stomach and rectum was found inflamed. The fresh plant applied to the skin produces vesication. Taken accidentally by man, it has occasioned profuse watery stools, violent colic and vomiting, collapse, and death.

Medical Uses.—In the Hippocratic writings bryonia-root prepared with wine was recommended for tetanus, prolapsus of the rectum, and uterine ulcers. Dioscorides in addition speaks of the young sprouts as purgative and diuretic, and of the root applied in poultices, etc. for the cure of various cutaneous eruptions, abscesses, etc. One species, the black, was especially recommended in affections of the spleen and kidneys and as a remedy for epilepsy. Later ancient writers speak of it as an emmenagogue and abortifacient and as a remedy for the bites of venomous animals and insects. In modern medicine it has been principally employed as a hydragogue cathartic in *dropsy* in the same manner as jalap. In certain cases of *epilepsy* depending upon intestinal worms it has effected a cure. It has been used in chronic intermittent fever with enlargement of the spleen, and in chronic *bronchitis* with serous effusion in the air-tubes. It has also been recommended in the catarrhal stage of *whooping cough*. Externally, it has been employed as a rubefacient or vesicant in cases of *hydrarthrosis*, chronic articular and muscular *rheumatism*, and *glandular* engorgements. Slices of the fresh root have been applied behind the ears of children as a substitute for suppressed eruptions during dentition, and the juice has been used topically in *scabies*.

The *dose* of the powder is from 10 to 60 grains (Gm. 0.60–4.00). An infusion made with 2 drachms of the root in 8 fluidounces of water may be prescribed in doses of 2 fluidounces.

Tapuya-root has been sufficiently tested in Europe to prove that it is a very feeble remedy for *syphilis* and *scrofula*. In a few cases only did it seem to be useful in superficial and glandular forms of either disease, and then only when reinforced by other medicines or a severe regimen.

BUCHU, *U. S.*—BUCHU-LEAVES.

Buchu folia, Br.; *Folia bucco*, *Folia diosmæ*, s. *barosmæ*.—*Feuilles de bucco* (*booko*, *buchu*), Fr.; *Buckublätter*, *Buccoblätter*, G.

The leaves of—1. *Barosma betulina*, *Bartling*; 2. *Barosma crenulata*, *Hooker*; 3. *Barosma serratifolia*, *Willdenow*, s. *Diosma serratifolia*, *Curtis*. Bentley and Trimen, *Med. Plants*, plates 45, 46, 48.

Nat. Ord.—Rutacæ.

Origin.—The three plants are shrubs attaining a height of several feet; the short-stalked or nearly sessile leaves are opposite or subalternate; the flowers, which are handsome, have the calyx deeply five-lobed; the five petals white or pinkish, longer than the calyx, and glandular punctate on the back, and the five hypogynous stamens alternating with the petals. The fruit consists of five carpels, which are united by the inner margin, are dehiscent above by their ventral suture, and contain each one smooth, glossy, and black seed. The shrubs are indigenous to the southern portion of Africa, more particularly to various parts of Cape Colony.

Much uncertainty has prevailed in relation to the diagnosis of the two first-named species, due to the great variation of the leaves. At the present time the following synonyms appear to be generally admitted:

1. *Barosma betulina*, *Bartl.*; *Diosma betulina*, *Thunb.*; *D. crenata*, *D. C.*, *Lindl.*, and

others; 2. *B. crenulata*, *Hook.*; *B. crenata*, *Kunze*; *D. crenata*, *Lin.*; *D. crenulata*, *Lin.*; *D. odorata*, *D. C.*; *D. latifolia*, *Lodd.*

Description.—The leaves of the first species constitute most of the so-called *short buchu* of the market; they are $\frac{1}{2}$ to $\frac{3}{4}$ of an inch (12 to 19 Mm.) long, obovate or

FIG. 43.

Buchu-leaves: *a, b*, *Barosma crenata*, *Kze.*; *c, d*, *Bar. betulina*, *Bartl.*; *g, h*, *Bar. serratifolia*, *Willd.*; *e, f*, *Empleurum serrulatum*, *Ait.*—*b, c, f, g*, natural size.

rhomboid-obovate, cuneate below, usually obtuse, and with the apex recurved; margin sharply serrate, each serrature containing a gland; base almost entire; texture cartilaginous.

The second species likewise contributes to the short buchu, the larger leaves being occasionally held as an *intermediate* variety between the short and the long. The leaves vary between $\frac{3}{4}$ and $1\frac{1}{4}$ inches (19 and 31 Mm.) in length, and between oval and ovate or obovate in shape, obtuse above, margin serrulate or crenate, each crenature with a gland.

The leaves of the third species differ materially in shape from the preceding; they constitute the *long buchu* of our commerce, are rather thinner than the two preceding kinds, 1 to $1\frac{1}{2}$ inches (25 to 38 Mm.) long, linear-lanceolate in outline, tapering toward both ends, obtuse, margin serrulate, with a gland in each serrature, midrib prominent, with four lateral veins running nearly parallel to the margin.

Buchu-leaves are smooth, have a dull-green color, are paler on the lower surface, and have numerous large oil-cells, which render the leaves pellucid-punctate when held up to the light; they have a strong peculiar odor and a bitterish and aromatic taste. Prof. Flückiger (1873) has observed a layer of colorless cells between the epidermis of the upper side and the green tissue, which cells yield a large quantity of mucilage to water.

The leaves of *Barosma Eckloniana*, *Berg.* seem to be occasionally imported; they are nearly an inch long, oval, rounded at the base, strongly crenate, and grow from pubescent shoots (*Pharmacographia*).

Constituents.—The leaves of the first species yield from $\frac{1}{2}$ per cent. (Flückiger, 1880) to 1.21 (Bedford, 1863) or 1.63 (Flückiger and Hanbury, 1874) per cent., those of the third species 0.66 per cent., of volatile oil (Bedford). The two oils agree with each other in sensible properties, and probably also in composition. In odor they resemble peppermint; exposed to a low temperature, they separate *barosma camphor* or *diosphenol*, a stearopten which, after recrystallization from alcohol, is in colorless needles which fuse at 83° C. (181.4° F.), sublime at the heat of a steam-bath, and boil at 233° C. (451.4° F.), but cannot be distilled without partial decomposition. Pure diosphenol has a slightly aromatic odor and a peculiar taste; its composition is $C_{14}H_{22}O_3$. Its alcoholic solution is colored dingy black-green by ferric chloride; its solution in alkalis is precipitated by carbonic acid. It is probably this camphor which was described by Landerer (1844) as *diosmin*, and observed in a tincture of buchu three years old. The diosmin of Brandes was an extract-like body of a bitterish taste. Prof. Wayne (1876) obtained salicylic acid from the distillate of a lot of buchu-leaves; recent investigations having failed to detect this acid, its presence may probably be accounted for by an accidental admixture of the leaves. Buchu-leaves possibly contain a body similar to rutin (Flückiger). Besides the constituents mentioned, resinous, gummy, albuminous, and coloring matters and saline

compounds have been observed. *B. crenulata* yields 4 to 5.4 per cent. of ash; *B. betulina*, 4.4 to 4.7 per cent.; and *B. serratifolia*, 5 to 5.5 per cent. (H. W. Jones, 1879).

Impurities and Substitutions.—The short buchu is sometimes mixed with the flowers and the non-aromatic capsules, which must be separated. The long buchu is usually cleaner, but is occasionally mixed with or replaced by the leaves of *Empleurum serrulatum*, *Aiton*, nat. ord. Rutaceæ, indigenous to Southern Africa; they are 1 to 3 inches (25 to 75 Mm.) long, have a narrow linear shape, a serrulate margin, and an acute glandless apex; their odor is different from buchu. From other leaves buchu is readily distinguished by the characters given above.

Off. Prep.—Extr. buchu fluid., *U. S.*; Infusum buchu, Tinet. buchu, *Br.*

Physiological Action and Medical Uses.—Buchu excites a sense of warmth in the stomach, which diffuses itself over the whole body. It quickens the appetite and digestion, and favors the secretion of urine, giving it a peculiar aromatic smell. Large doses excite vomiting and purging. The Hottentots, from whom a knowledge of this medicine was derived, employed an ointment made from it as a vulnerary, and a vinous tincture as a remedy for various disorders of the stomach and the urinary organs. It is chiefly in the last-named affections that it used—viz. *chronic pyelitis, cystitis, and urethritis*. It is most commonly, perhaps, resorted to as a remedy for *catarrh of the bladder* caused by an extension of urethral irritation, but catarrh of the whole urinary passage is favorably influenced by it, as well as vesical tenesmus and atony of the bladder when they are attendant symptoms. Like other bitter plants containing a volatile oil, it may sometimes be useful in *feeble digestion* with flatulence. It may be administered in substance (gr. xx—gr. xxx, *Gm.* 1.30–2.00), or in the infusion or fluid extract. The former is prepared with an ounce of buchu to a pint of boiling water. *Dose*, 1 or 2 fluidounces (*Gm.* 32–64). An infusion made with buchu and the analogous plant, *uva ursi*, is generally preferable to one containing either alone: $\mathcal{R}$. Buchu, *uvæ ursi*, āā 5j–5iv (*Gm.* 4–16); hot water *Qj*. Digest for half an hour in a covered vessel and strain. *Dose*, from $\frac{1}{2}$ fluidounce to 2 fluidounces three times a day.

CACTUS.—CACTUS.

Cactier, *Fr.*; *Kaktus*, *Fackeldistel*, *G.*

Nat. Ord.—Cactaceæ.

Description.—Of the numerous species of these American plants which are more or less medicinally employed in their native country the following has recently attracted attention:

CACTUS (CEREUS, *Miller*) GRANDIFLORUS, *Linné*.—Night-blooming cereus, *E.*; Cierge à grandes fleurs, *Fr.*; Königin der Nacht, *G.*—It is indigenous to tropical America, and frequently cultivated for ornament. The stem is weak, branching, fleshy, green, and five- or six-angled, the angles being beset with clusters of five or six short radiating spines. The numerous imbricate calyx-lobes are linear, acute, brownish, the inner ones yellow. The lanceolate petals are of a white color. The flowers, which open in the evening and wither by the following morning, are very fragrant and produce an orange-colored, internally white, berry of the size of an egg. The fleshy branches, with the flowers, are imported preserved by alcohol. The juice has an acid taste. The plant has not been analyzed.

Allied Plants.—CACTUS (CEREUS, *De Candolle*) FIMBRIATUS, *Lamarek*.—The stem is erect, eight- to ten-angled, with clustered spines, and bears rose-colored flowers and red fruits. The juice is acid; the berries are acidulous.

CACTUS (CEREUS, *De Candolle*) PANICULATUS, *Lamarek*.—It is tall, tree-like, with a quadrangular stem and numerous crenate and spiny branches. The large yellowish berries have a sweet and acidulous taste.

CACTUS (CEREUS, *Miller*) FLAGELLIFORMIS, *Linné*.—Stem and branches are weak, thin, several feet long, ten-angled, warty, spiny, and bear red flowers and small woolly berries. The acidulous juice is reputed to be anthelmintic. It contains, according to L. A. Buchner (1836), acid calcium malate, potassium acetate, albumen, mucilage, etc.

OPUNTIA VULGARIS, *Miller*, s. CACTUS OPUNTIA, *Linné*.—Prickly pear, *E.*; Figue de Barbarie, *Fr.*; Judische Feige, *G.*—It is indigenous to the West Indies and near the coast of North America northward to Massachusetts. The branches are broadly obovate, green, fleshy, bristly, and have small appressed subulate leaves, yellow flowers, and red bristly berries with an acidulous sweet pulp.

MAMMILLARIA SIMPLEX, *Harroth*, s. CACTUS MAMMILLARIS, *Linné*.—The stem is simple, obovate-oblong, about 8 inches (20 *Cm.*) high, mammilar-tuberculate, spiny, and produces small white flowers and bright-red berries.

MELOCACTUS COMMUNIS, *Link et Otto*, s. *CACTUS MELOCACTUS*, *Linne*.—The stem is subglobose, about sixteen-furrowed, the ridges beset with clustered brown spines, flowers and berries red.

The succulent stems of the last-named three species and of many others are bruised and employed as discutient applications. The red-juiced berries when eaten are stated to color the urine red.

Medical Action and Uses.—Long ago the cactus- (*grandiflorus*) juice was known to be extremely acrid, producing vesicles and pustules on the skin, and internally vomiting, colic, and bloody stools. In substance and in tincture it was employed as a vermifuge (*Richter, Arzneimittellehre*, ii. 290). In 1868 it was stated that the tincture of this plant had been used advantageously by Rubini in functional *palpitation of the heart* (*Med. Record*, iii. 299); in 1879, Dr. N. S. Davis confirmed the earlier statement (*Phil. Med. Times*, x. 26); and in 1883, Dr. Byrd reported that it palliated the abnormal action and the pain in rheumatic disorders of the heart, and was even beneficial to the rheumatism itself (*ibid.*, xii. 811). It was used as a fluid extract and in doses of 10 or 12 drops. Dr. Cullen claims for the medicine even more remarkable powers in "functional heart disease" with "lips and fingers almost stagnant with blood," and in which he had tried without success "the usual remedies, digitalis and bromide of potassium" (*Therapeutic Gaz.*, Dec. 1882). On the other hand, Dr. O'Hara finds the medicine peculiarly efficacious in removing the effects of degenerative lesions of the heart, including dropsy, angina, etc. (*Med. News*, xliii. 526). It is evident that more precise information is needed to determine the virtues of *Cactus grandiflorus*.

CADMII IODIDUM, *Br.*—IODIDE OF CADMIUM.

Cadmium iodatum, Iodidum cadmicum.—*Iodure de cadmium*, Fr.; *Jodcadmium, Kadmiumjodür*, G.

Formula CdI_2 . Molecular weight 365.

Preparation.—This salt is generally prepared by digesting an excess of metallic cadmium with iodine and water until a colorless solution is obtained, which is filtered and evaporated. It may also be obtained by dissolving 20 parts of potassium iodide and 15 parts of cadmium sulphate in water, evaporating the solution to dryness, exhausting the residue with warm absolute alcohol, and filtering and crystallizing (*A. Vogel*, 1863).

By the first process a direct combination of the metal and iodine is effected, while in the second process a mutual decomposition of the two salts takes place, with the formation of cadmium iodide and potassium sulphate. The latter, being insoluble in alcohol, remains upon the filter: $\text{CdSO}_4 + 2\text{KI}$ yields $\text{CdI}_2 + \text{K}_2\text{SO}_4$.

Properties and Tests.—Iodide of cadmium exists in white, flat, micaceous crystals of a pearly lustre, inodorous, of a nauseous metallic taste, permanent in the air, soluble in alcohol, and at the ordinary temperature in a little more than its own weight of water. Heated at about 310°C . (600°F .), it forms an amber-colored liquid, and at a dull red heat is decomposed, vapors of iodine being given off. The aqueous solution, which reddens litmus, yields with sulphuretted hydrogen a yellow precipitate of CdS , which is insoluble in sulphhydrate of ammonium (difference from arsenic), and the filtrate from this precipitate is not affected by ammonia, sulphhydrate or carbonate of ammonium (absence of the metals of the zinc group and of the earths and alkaline earths), and after applying these tests leaves no residue when evaporated to dryness and ignited (absence of alkalies). The presence of heavy metals would be indicated by the brown or blackish discoloration in the yellow color of the precipitated sulphide. Ammonia would be detected by the odor given off on the addition of an excess of potassa solution. Most other cadmium salts differ considerably from the iodide in appearance. Their possible presence, however, may be inferred by applying the following test of the British Pharmacopœia: "10 grains dissolved in water, and nitrate of silver added in excess, give a precipitate which, when washed with water and afterward with half an ounce of solution of ammonia, and dried, weighs 12.5 grains." Any deviation from this weight indicates the presence of foreign salts.

Off. Prep.—*Unguentum cadmii iodidi, Br.*

Medical Action and Uses.—According to Garrod, it has the same action and may be employed in the same cases as yellow iodide of lead, particularly in *scrophulous* enlargement of the *glands* and chronic skin diseases. It does not stain the skin. An ointment may be used containing 60 grains of the salt to 1 ounce of lard (*Gm.* 4 to *Gm.* 32).

CADMIUM SULPHAS, U. S. 1870.—SULPHATE OF CADMIUM.

Cadmium sulphuricum, Sulfas cadmicus.—*Sulfate de cadmium*, Fr.; *Schwefelsaures Cadmiumoxyd, Kadmiumsulfat*, G.

Formula $3\text{CdSO}_4 \cdot 8\text{H}_2\text{O}$. Molecular weight 767.4.

Preparation.—This salt is readily prepared by dissolving 2 parts of metallic cadmium in 2 parts of sulphuric acid which has been diluted with 10 or 12 parts of water and mixed with 1 or $1\frac{1}{4}$ parts of nitric acid. Cadmium dissolves slowly in diluted sulphuric acid, with the liberation of hydrogen, but in the presence of nitric acid it is readily dissolved, with the evolution of nitric oxide, according to the equation $3\text{Cd} + 6\text{H}_2\text{SO}_4 + 4\text{HNO}_3 = 3\text{CdSO}_4 + 8\text{H}_2\text{O} + 4\text{NO}$. Sufficient heat will be generated to cause the reaction to proceed briskly. When it slackens heat is applied, and the whole evaporated to dryness to expel excess of acid; the residue is dissolved in three times its weight of water, the solution filtered, evaporated to one-half, and set aside to crystallize. The crystals are collected upon a filter and dried at a moderate heat. The mother-liquor may be made to yield more crystals by further evaporation. From the last portions the cadmium may be obtained by precipitation with zinc.

Properties and Tests.—Sulphate of cadmium crystallizes in colorless rhombic prisms, which effloresce somewhat in the air, have an astringent and strongly metallic taste, and change the color of blue litmus-paper to red. It dissolves at 23°C . (73.4°F .) in 1.6 parts of water, is somewhat more soluble in hot water, and is insoluble in alcohol; at 100°C . (212°F .) it loses 11.8 per cent. (5 molecules) of water, and the remainder when heated to redness; at a full red heat one half of the acid is also expelled. Its purity may be ascertained by precipitating the solution of 10 grains of the salt with dilute potassa solution, and after washing the precipitate igniting it; it should weigh 5 grains; or, 10 grains of cadmium sulphate dissolved in water, and barium nitrate added in excess, yield a precipitate which after washing and heating should weigh 9.1 grains.

Medical Action and Uses.—Sulphate of cadmium is astringent and irritant, like sulphate of zinc, but is much more powerful. A grain taken internally has occasioned profuse salivation, vomiting, colic, diarrhoea, and tenesmus. Injected subcutaneously, it has caused giddiness, retarded pulse and respiration, fainting, and sometimes spasms. In doses of from $\frac{1}{4}$ grain to 1 grain hypodermically, or of from 6 to 10 grains internally, it is fatal to rabbits. In continued small doses it occasions in these animals indigestion, emaciation, subcutaneous hæmorrhages, and fatty degeneration of the heart and liver, with inflammation of the kidneys. It has been chiefly used in *conjunctivitis*, ulcers and opacities of the *cornea*, *otorrhœa*, and *gleet*, in solutions containing from 1 to 8 grains (Gm. 0.06–0.50) of the salt in 2 ounces of water. *Bromide of cadmium*, although not used in medicine, is employed by photographers, and is sometimes found in commerce labelled bromide of ammonium. In a published case two ladies, misled by this error, took a small but uncertain dose of the former salt. It occasioned violent vomiting and a severe burning pain in the throat, œsophagus, and stomach, followed by purging and collapse. No cerebral symptoms were present. For several days both patients were confined to bed and their stomachs continued irritable (*Wheeler, Boston Med. and Surg. Jour.*, Oct. 1876, p. 434).

CADMIUM.—CADMIUM.

Cadmium, Fr., G.; *Kadmium*, G.

Symbol Cd. Atomicity bivalent. Atomic weight 111.8.

Origin and Preparation.—This metal is found near Bishopstoun, Scotland, in the form of sulphide as the mineral Greenockite, but it is more frequently present in small quantities in some kinds of calamine, blende, and other zinc ores. It was discovered by Stromeyer and Hermann in 1817. Cadmium being more volatile than zinc, it is contained in the first portions obtained on the distillation of the latter metal, and its presence is indicated by the appearance of a brown flame (the so-called “brown blaze”) before the greenish-white flame of burning zinc is noticed. To obtain cadmium, the zinc, or the zinc oxide containing it, is dissolved in dilute sulphuric or muriatic acid, and the cadmium precipitated by metallic zinc; or, the acid solution is treated with sulphuretted hydrogen to precipitate the cadmium as yellow sulphide, which is used as a pigment under the name of *cadmia*; the sulphide is dissolved in strong hydrochloric acid, the solution precipitated by an excess of ammonium carbonate to remove copper and traces of zinc, and the washed and dried precipitate mixed with lampblack and distilled.

Properties.—Cadmium is a malleable and ductile metal having the color of tin, and like the latter it emits a crackling sound when bent. It crystallizes readily in octahedrons, is superficially tarnished on exposure to the atmosphere, becomes brittle at 82° C. (180° F.), fuses near 315° C. (592° F.) (B. Wood, 1862), and volatilizes, according to Becquerel (1863), at 720° C. (1319° F.), and according to Deville and Troost at 860° C. (1580° F.) Its density varies between 8.60 and 8.69; its vapor is dark-yellow, has a nauseous taste and burns with a dark-red flame to brown oxide. In the presence of acids cadmium slowly decomposes water, hydrogen being given off; but nitric acid dissolves the metal readily. The salts of cadmium are mostly white; those soluble in water have an acid reaction and a disagreeable metallic taste. Their solutions, treated with sulphuretted hydrogen or ammonium sulphhydrate, afford orange-yellow precipitates of CdS , which is insoluble in an excess of the precipitate and in dilute acids and alkalis. Caustic alkalis produce white precipitates of CdH_2O_2 , which is soluble in ammonia, but not in potassa or soda. The soluble carbonates, phosphates, and oxalates, and ferrocyanide of potassium, produce white precipitates.

Tests.—The impurities likely to be present in metallic cadmium are mainly zinc and copper, the former of which is recognized by precipitating the solution in nitric acid with sulphuretted hydrogen, when the filtrate from the bright orange-yellow precipitate will yield a white precipitate on the addition of ammonia and ammonium sulphhydrate. When the solution in nitric acid is precipitated by slight excess of ammonium carbonate the filtrate will have a blue color if copper be present.

Off. Prep.—Cadmii iodidum, *Br.*; Cadmii sulphas.

CAFFEA.—COFFEE.

Semen Coffeæ.—Café, *Fr.*; Kaffee, *G.*

The fruit of *Coffea arabica*, *Linneé*. Bentley and Trimen, *Med. Plants*, 144.

Nat. Ord.—Rubiaceæ, Coffeineæ.

Origin.—Coffee is indigenous to tropical Africa, more particularly to Abyssinia; possibly also to Southern Arabia, but this is denied by some authors. It grows wild in Central Africa and on the coast of Mozambique, and was introduced into Java near the close of the seventeenth century, and into the West Indies and South America during the eighteenth century. At present it is very extensively cultivated in most tropical and subtropical countries. The Liberian coffee-plant is a distinct species, *C. liberica*, *Hiern* (1877), which seems to be less subject to disease, and has been successfully introduced in the East Indies. The seeds of several other species of *Coffea* are used in their native countries, but do not appear to be of commercial importance.

In its wild state the coffee tree attains a height of from 20 to 30 feet (6 to 9 M.), and has somewhat the aspect of a cherry tree, but its bark is whitish and furrowed and its numerous branches are opposite. In cultivation it is trimmed down to the height of about 6 feet (1.8 M.). The smooth evergreen leaves are ovate-oblong, rather acuminate, 4 to 6 inches (10 to 15 Cm.) long, $1\frac{1}{2}$ to 2 inches (37 to 50 Mm.) wide, dark-green and glossy above, paler beneath, and somewhat glandular near the midrib. Flowers in clusters of three to five or seven, with a small five-lobed calyx, a white tubular five-lobed corolla, five stamens, and one pistil with a bifid style. The fruit is an oval, deep-purple, two-seeded drupe, the parchment-like endocarp enclosing two plano-convex seeds, which are placed together by their flat sides and constitute the raw coffee of commerce. The Liberian coffee-plant has the corolla six- to nine-lobed and the fruit globular.

When the berries are ripe they are gathered and freed from the pericarp and scanty pulp by suitable apparatus and washing; the seeds are then dried, and subsequently freed from the parchment-like testa by passing them between wooden rollers and by winnowing. The seeds constitute one-third the weight of the ripe berries.

The use of coffee as a beverage appears to have spread from Abyssinia first to Arabia early in the fifteenth century, to Constantinople in 1554, and to France and England after 1640. Until the beginning of the eighteenth century the supply was exclusively obtained from Arabia, where, in the district of Yemen, the plant is cultivated and yields the small seeds so highly valued as Mocha coffee. The East Indian coffees consist usually of the largest seeds; West Indian and South American coffees are generally intermediate between the two varieties previously named.

Description.—The seeds are oval, longitudinally grooved upon the flat side, usually almost completely deprived of the parchment-like, finely-wrinkled testa, fragments of which remain in the groove and sometimes upon the back. The horny albumen is of the

shape of the seed, according to the variety of a yellowish, brownish, bluish, or greenish tint, and is folded, or rather rolled up, whereby the groove is produced. The embryo is situated under the convex side near one end, is slightly curved, and occupies about one-fourth the length of the seed. Raw coffee has a very faint odor and a sweetish, slightly astringent, and bitterish taste. The commercial varieties vary considerably in flavor, in size, and in the shade of color. On keeping, coffee loses during the first year about 8 per cent. in weight, principally moisture; during the second, 5 per cent., and during the third year 2 per cent., the flavor being at the same time greatly improved.

Constituents.—The sweetish pulp of the pericarp contains several sugars, of which Boussingault (1881) found 2.37 per cent. cane-sugar, 8.73 per cent. invert-sugar, and 2.21 per cent. mannit. According to Payen's analysis (1849), coffee contains 13 per cent. of fat, 15.5 of glucose, dextrin, and an undetermined vegetable acid, 10 of vegetable casein, 5 of chlorogenate of caffeine and potassium, 3 of nitrogenized principle, 0.8 of caffeine, 0.001 of solid volatile oil, 0.002 of liquid aromatic principle soluble in water, 6.7 of ash, and 12 of moisture, the remainder being cellulose. The fat consists of palmitin and olein. The acids contained in coffee have been the subject of repeated investigations. These render it probable that, besides a little citric acid, the principal one is *caffeo-tannic acid*, which, according to Rochleder, is Payen's *chlorogenic acid*; its precipitate with gelatin is soluble in the tannin solution; tartar emetic does not precipitate it, but it yields with lead salts and baryta solution yellow precipitates. Vlaanderen and Mulder (1858) separated this principle under the name of *caffic acid*, and regard the other acids of coffee (*caffranic*, *carulic*, and *caffelic*) as products of oxidation; and they believe the various colors of raw coffee to be due to mixtures of these derivatives. They consider chlorogenic as a mixture of their caffeic and cerulic acids; Rochleder's *viridinic acid* (1848) may be a similar mixture. The *caffic acid* of Hlasiwetz (1867) is obtained by continued boiling of caffeo-tannin with excess of potassa solution and separation by sulphuric acid. When pure it has the composition $C_9H_8O_4$, is in straw-yellow crystals, forms mostly yellow-colored salts, and, like the amorphous gum-like caffeo-tannin, yields with fusing potassa protocatechuic acid, $C_9H_6O_4$. By dry distillation pyrocatechin is obtained. Zwenger and Siebert (1861) obtained from Java coffee 0.3 per cent. of kinic acid, which is most likely the coffic acid of Stenhouse, obtained (1854) from coffee-leaves, and which readily yielded kinone when treated with manganic deutoxide and sulphuric acid. (For a description of *Caffeine* see below.)

The roasting of coffee, which is best accomplished at a temperature of about 250° C. (482° F.), renders the seeds pulverizable, and at the same time gives them a more agreeable taste and enables them to yield more of their constituents to water. The coffee thus acquires a chestnut-brown color and loses about 18 per cent. of its weight. The generation of gaseous compounds ruptures the cells, and a peculiar and agreeable aroma is produced, probably through the decomposition of the fat and tannin. But Payen's (as well as Rochleder's) investigations failed to point out the principle to which the changes are due. Very probably they depend upon the decomposition of several of the organic compounds, and unquestionably upon the production of a pyrogenated volatile oil, to which the grateful aroma is due. Caffeine does not partake of these changes, except that it is slowly volatilized at the temperature stated; hence the roasting of coffee ought to be effected in closed vessels. Bernheimer (1880) found nearly one-half of the products of roasting to consist of palmitic acid, the remainder being acetic acid, carbonic acid, probably acetone, hydroquinone, pyrrol, methylamine, .18 to .28 per cent. caffeine, and .04 or .05 *coffeol*, $C_8H_{10}O_2$, to which the aroma of coffee is due; it is an oil boiling at 195° C. (383° F.), and is probably a methylether of saligenin.

Coffee yields 4 to 5 per cent. of ash—Mocha coffee as much as 7.84 per cent.—consisting chiefly of carbonates and phosphates of potassium, sodium, magnesium, and calcium, the earth salts amounting to one-seventh or one-sixth of the weight.

ADULTERATIONS.—Coffee-seeds are not subject to adulteration, except that inferior qualities are mixed with or sold for the better varieties, and that the brown, yellow, or discolored seeds are occasionally artificially colored with indigo, Prussian blue, and other substances. These pigments usually adhere merely superficially, and may be removed by washing with water. Ground coffee is frequently adulterated with roasted amylaceous seeds and bitter roots, chiefly chicory, and occasionally dandelion. Roasted coffee yields with cold water a brownish-yellow infusion, while that of the adulterants is dark-brown or red-brown. F. M. Rimmington (1880) suggested the following process for the detection of adulterations: the coffee is boiled with water and a little sodium carbonate, then washed with water and macerated in a weak solution of chlorinated lime for 2 or 3 hours, when

the ground coffee will form a dark stratum and the ground chicory a nearly white layer; the microscope will reveal other admixtures.

The husks of coffee have been to some extent used under the name of *sultan coffee* and *sacca coffee*; they are said to improve the flavor of coffee, but, according to Peckolt, contain only .082 per cent. of caffeine. The roasted flattish ovate seeds of *Cassia occidentalis*, *Linne*, are used in the tropics as a substitute for coffee under the name of *negro coffee* or *Mogdad coffee*, and have been met with as an adulteration in Europe; they do not contain caffeine, and are best detected by the microscope. Mogdad coffee yields 4 to 5 per cent. of ash; roasted chicory, 10 to 11 per cent.; roasted rye and wheat, 2 to 3 per cent.

CAFFEINA, *U. S.*; COFFEINUM, THEINUM, *P. G.*—Caffeine, caffeia, theine, guaranine, *E.*; caféine, théine, *Fr.*; Koffein, Kaffein, Thein, *G.* Formula ($C_8H_{10}N_4O_2.H_2O$). Mol. weight 212.—This, the most important constituent of coffee, is obtained by precipitating the decoction of coffee with acetate of lead, removing the excess of lead from the filtrate by sulphuretted hydrogen, neutralizing by ammonia, evaporating, and recrystallizing (Garot). Prof. E. S. Wayne (1875) recommended the following process, which has been found very serviceable: 2 parts of powdered coffee or tea are boiled with 3 parts of levigated litharge and sufficient water; the acids combine with the lead; the nearly colorless filtrate is freed from lead by sulphydric acid, and on concentration will yield most of the alkaloid in colorless crystals; the yellowish mother-liquor requires to be treated with animal charcoal, when the remainder of the alkaloid is likewise obtained colorless. Good coffee yields between 0.8 and 1.0 per cent., coffee-leaves 3 per cent., maté or Paraguay tea and Chinese tea between 1.1 and 1.25, cocoanuts 2.13, and guarana about 5 per cent. of caffeine. Caffeine crystallizes in colorless or white, flexible, silky needles or thin long prisms, which are inodorous, of a faintly-bitter taste, fusible, and sublimable without decomposition. It is soluble in 75 parts (*U. S.*), 80 parts (*P. G.*), of water, and in 35 parts (*U. S.*), about 50 parts (*P. G.*), of alcohol at 15° C. (59° F.); in 160 parts of absolute alcohol; in about 6 parts (*U. S.*), 9 parts (*P. G.*), of chloroform; in 9.5 parts (*U. S.*), 2 parts (*P. G.*), of boiling water. It is soluble in about 500 parts of ether, slightly soluble in carbon disulphide, and dissolves freely in boiling alcohol. These solutions have a neutral reaction to test-paper. Benzol, chloroform, or amyl alcohol, when repeatedly agitated with its solution in acidulated water, dissolves the whole of the caffeine (Dragendorff). Crystallized from alcohol or ether, it is anhydrous; crystallized from water, it contains 8.5 per cent. (1 molecule) of water, with which it parts at above 100° C. (212° F.); when heated to above 180° C. (356° F.) it sublimes without leaving any residue. The anhydrous crystals have the composition $C_8H_{10}N_4O_2$, and contain 28.8 per cent of nitrogen. Caffeine, moistened with strong nitric acid or dissolved in chlorine-water and evaporated at the heat of a water-bath, leaves a reddish-yellow residue, which becomes purple by ammonia from the formation of *mucochin* (Schwarzenbach). Concentrated aqueous solutions of caffeine give with silver nitrate a white granular, crystalline precipitate; with mercuric chloride, long needles soluble in hydrochloric acid; with palladium chloride, yellow scales; with picric acid, no precipitate; the alkaloid dissolves in sulphuric and in nitric acid, and the solution remains colorless for several hours (Dragendorff).

Caffeine is *methyl-theobromine*, and may be formed by heating theobromine-silver with methyl iodide in sealed tubes. According to Mulder and Günther, it dissolves more or less readily in solutions of citric, tartaric, oxalic, and acetic acids, and on cooling caffeine crystallizes. Hager, and afterward Haaxman (1877), ascertained that commercial *citrate* and *valerianate* of caffeine consist merely of the alkaloid with some acid adhering. Lloyd (1881) and Biedermann (1882) showed that caffeine salts with organic acids may be obtained from chloroform, and that they are easily decomposed by water. Tanret (1882) regards the solutions of caffeine in sodium benzoate, cinnamate, and salicylate as definite compounds suitable for hypodermic use; these solutions may be made so as to contain in each Ccm. (15 minims) 0.20 Gm. (3 grains) of caffeine, and with sodium salicylate 0.30 Gm. (4½ grains). The salts with mineral acids have an acid reaction to test-paper, and are decomposed by water or alcohol. Their concentrated solutions yield with hydrargyro-potassium iodide a precipitate which soon crystallizes in needles. Similar precipitates obtained with other alkaloids remain amorphous (Delffs, 1854). Diluted acidulated solutions of caffeine are not precipitated by Mayer's reagent (Dragendorff).

When caffeine is heated with alcoholic potassa or with solution of barium hydrate, water is assimilated, carbonate of barium is precipitated, methylamine and a little ammonia are given off; and from the residue Strecker obtained (1861) a strong and

uncrystallizable base, *caffeidine*, $C_8H_{12}N_4O$, which is easily soluble in water and alcohol, but to a slight degree in ether. The decomposition takes place mainly according to the equation $C_8H_{10}N_4O_2 + H_2O = C_7H_{12}N_4O + CO_2$. O. Schultzen (1867) and F. Rosengarten (1871) proved that by prolonged boiling a further decomposition takes place, affecting chiefly the *caffeidine*, and resulting in the production of sarkosine, formic acid, methylamine, and ammonia; thus: $C_8H_{10}N_4O_2 + 6H_2O = C_3H_7NO_2 + CH_3O_2 + 2CH_3H_2N + NH_3 + 2CO_2$.

Allied Drugs.—SEMEN (NUCES) COLLE.—Cola-nut, Guru-nut, *E.*: Noix de cola, Noix de gourou, Café du Soudan, *Fr.*: Kolanuss, *G.*—The tree, Cola (*Sterculia*, *Beauvois*) *acuminata*, *R. Brown*, (nat. ord. *Sterculiaceae*), is indigenous to tropical Africa, and is also found in tropical America; the yellow flowers produce five foliicles, each containing one seed. The latter in the fresh state are brown externally and purplish- or violet-colored internally; after drying, reddish or brown, somewhat mottled on the surface. They are about an inch (25 Mm.) long, oblong-ovate, flattish on one side, and have a slight nutmeg-like odor and a mild somewhat aromatic taste; in the fresh state they are bitter. Daniell showed the presence of caffeine, and Attfield (1865) obtained 2.13 per cent. of this alkaloid, besides 1.5 fat and volatile oil, 42.5 starch, 10.7 sugar and gum, 6.3 protein compounds, and 3.2 ash. Heckel and Schlagdenhauffen (1882) obtained similar results, and found also .023 theobromine and 1.62 tannin. The seeds are said to be used for clearing muddy water.

Physiological Action.—*On Animals*: In the last century coffee and tea used in experiments upon frogs were known to produce in these animals paralysis of the hind legs. More recently similar experiments with caffeine upon a great variety of animals—including dogs, rabbits, cats, birds, and fish—showed that this substance is fatal to them by producing, first of all, spasm, and then paralysis. 1 grain of it thrown into the veins of a small dog was sufficient to destroy its life, but in a large animal of the same species even 30 grains produced only salivation, muscular rigidity, exhaustion, hurried breathing, and defecation. In all the experiments with full doses hyperæsthesia was apparently manifested, with exaggerated reflex irritability at first, and afterward still more decidedly, the heart and pulse at first beating more frequently, but gradually settling down to their normal rate or even lower. In most cases, and however the caffeine was introduced, increased defecation or diarrhœa occurred. The muscular rigidity it causes is followed by complete resolution, which, however, is not paralysis, since direct irritation of the limbs revives the rigid contraction. Indeed, it is eminently the property of caffeine to increase reflex excitability until it is extinguished by the approach of death. As an examination of the spinal cord does not exhibit any uniform condition after death from this substance, and especially no marked degree of hyperæmia, it has been doubted whether the muscular spasms are of spinal origin alone, or are partly due to the state of the blood-vessels in the muscles themselves. It seems probable that both actions concur.

On Man: Since coffee was introduced into Arabia from Africa in the fifteenth century, numerous opinions have been expressed of its salutary and of its mischievous effects. The consequences of an abuse of tea were declared to be similar to that of coffee long before chemistry had demonstrated the identity of theine with caffeine. Among their evil effects were enumerated the following: indigestion, acidity, heart-burn, watchfulness, tremors, debility, irritability of disposition, and defection of spirits. By some persons both tea and coffee were accused of producing paralysis. Most of these effects are more likely to follow the habitual use of tea than of coffee, perhaps because, as a general rule, more of the former than of the latter is consumed; and the spinal symptoms, such as painful muscular tension and cramp and persistent wakefulness, are more apt to be produced by tea. In experiments undertaken with a number of selected healthy persons the operation of caffeine has been found to vary exceedingly; by the same dose some were scarcely at all affected, while others suffered from palpitation of the heart, a full, frequent, or irregular pulse, irritable bladder and difficulty of urination, trembling limbs, headache, roaring in the ears, flashes before the eyes, sleeplessness, phantasms, a sort of intoxication, and even delirium when a very large dose was taken, and a subsequent unfitness for bodily or mental labor. To illustrate the toxic effects of coffee the following examples may suffice: 50 minutes after taking a drachm of citrate of caffeine a burning sensation of the throat was complained of, and giddiness, with vomiting, purging, and abdominal pain. General paresis with tremor ensued, followed by collapse, but the mind remained clear (Routh, *Practitioner*, xxxi. 48). Fort took an infusion of 8 ounces of coffee in a quart of water in the course of a day. The pulse rose to 114, sleep was impossible, muscular spasms occurred all over the body, and were very painful in the extremities, chest, and throat. The tongue was dry, there was nausea with frequent liquid stools, and the pulse

ranged from 110 to 114, and was intermittent. The next day there were headache and anorexia (*Bull. de thérap.*, civ. 350). These effects, which may be called poisonous, illustrate the danger of exceeding due moderation in the use of coffee, for they show that it may, if immoderately consumed, tend to develop a morbid condition of the nervous system which must render it peculiarly liable to disease, although in a much less degree than opium or alcohol. Indeed, the excessive use of coffee is much more injurious to the spinal than to the cerebral functions. In its primary operation it agrees with those stimulants in exciting muscular and mental activity as well as cheerfulness, and in its after effects it does not tend to produce narcotism or stupor, but only that unsteadiness of the mind, and still more of the spinal functions, which denotes exhaustion. The experiments of Dr. Mary P. Jacobi in a case of exposed brain led her to a corresponding conclusion—viz. that under the influence of coffee “the amount of blood circulating in the brain is smaller, but it is brought to the nerve-tissues under increased pressure; hence assimilation of nutritive material should be increased in rapidity if lessened in quantity.” It agrees with tobacco, with Chinese and Paraguay teas, and with various other dietetic stimulants used by different nations, in the main features of its action. It results from some carefully conducted experiments that caffeine is diuretic in the sense of increasing the secretion of water by the kidneys, but that it diminishes all the solid constituents of the urine except the fixed salts; that the proportion of carbonic acid in the expired air declines under its use, and that its ultimate tendency is to diminish rather than increase the frequency, volume, and force of the pulse after its primary and transient stimulant impression has subsided. Its diuretic action is more prompt and less complete and durable than that of digitalis. Its final effect, in other words, is to lessen the amount of blood that is supplied to all the organs, and thereby their functional activity. This effect appears to be due to a contraction of the whole capillary system, in consequence of which the venous side of the circulation becomes distended with blood. To this mode of action may be referred the engorgement of the portal circulation which the immoderate use of coffee tends to produce, and which is shown by the formation of hemorrhoids and chronic enlargement of the liver. Possibly to this cause also may be attributed the dyspnoea and hurried breathing which some persons experience after an excessive use of coffee, and the coolness of the hands and feet which is more usual.

The moderation of tissue-waste which, it has been said, is an effect of coffee, as of other articles having the same general action and used by different nations, is illustrated by various well-established facts. The inhabitants of Central Africa, the native country of coffee, in their predatory excursions are said to subsist entirely upon a mixture of coffee and butter, which is prepared in masses of the size of a billiard-ball, one of which will keep a man in strength and spirits during a day's fatigue. Jomand says: “120 Gm. (4 oz.) of powdered coffee and 3 liters (8 pints) of an infusion made with 200 Gm. (6½ oz.) of different kinds of coffee enabled me to live for 5 consecutive days without lessening my ordinary occupations, and to use more, and more prolonged, muscular exercise than I was accustomed to, without any other physical injury than a slight degree of fatigue and a little loss of flesh.” The Belgian coal-miners live and work efficiently upon a ration of solid food much less than that of the French miners, and yet perform more labor than the latter. The only difference in the quality of their food consists in the Belgians receiving a ration of coffee, and to this is attributed their superior endurance. Such facts show that Böcker was in error when he alleged that coffee assists digestion only by hurrying forward the alimentary mass and preventing assimilation, and also when he concluded that they only who live to eat, and not those who eat to live, should use coffee with their meals. This is a notable instance of scientific error.

It may seem, at first sight, irrational that a substance which restricts tissue-waste should be used for the very purpose of quickening certain functions, and especially those of the brain. The mental exhilaration, physical activity, and wakefulness it causes explain the fondness for it which has been shown by so many men of science, poets, scholars, and others devoted to thinking. It has indeed been called “the intellectual beverage.” But all these occupations involve increased functional activity, and therefore increased waste of tissue, in the brain and spinal marrow—the very action which coffee is said to restrain. To reconcile these apparent incongruities it has been maintained that coffee does not act primarily as a cerebral stimulant, but only secondarily by removing the vascular plenitude occasioned by prolonged study, by a full meal, and especially by alcohol, opium, or other agents which directly tend to load the brain with blood—that if taken on an empty stomach it does not quicken the functions of the brain.

but, on the contrary, renders it dull and inapt for steady thought, creates general debility and nervousness, and frequently causes hæmorrhagia. During digestion, however, the case is different, particularly if a full and stimulating meal has been taken: the mind grows dull and sluggish, a tendency to sleep arises, and everything indicates an increased amount of blood in the brain. In like manner, prolonged mental labor produces cerebral plenitude and drowsiness. It is this condition, apparently, which coffee corrects by contracting the blood-vessels and relieving the brain of its oppressive load of blood. The habit of taking coffee at breakfast and after dinner is explained by the stimulant action (whether direct or indirect) which it exerts not only upon the nervous system generally, but especially upon the stomach and bowels: there can be no doubt that it quickens gastric digestion and relieves the sense of plenitude in the stomach, stimulates the secretion of bile, and by augmenting the peristaltic action of the intestine promotes defecation. It is quite as certain that, used to excess, it paralyzes the digestive function in all its steps, and leads to further disorders, of which the chief are congestion of the liver, constipation, and hæmorrhoids. Whether these effects are to be ascribed to a power in coffee to produce contraction of the capillary blood-vessels may be uncertain, but their reality is beyond doubt. To such an operation has also been ascribed an anaphrodisiac action of coffee which is alleged by Willis, Linnæus, and by numerous French writers, one of whom cites a Persian tale to the same effect. It would be singular if such were the case, when, as is well known, the consumption of coffee is greatest by the very nations most notorious for sexual excesses. It is not, however, without interest to remember that the use of coffee is universal and excessive in France, and that the smallness of the families of that country is quite exceptional.

Uses.—The mode in which coffee assists digestion has been described, and the popular use made of it to prevent or to relieve *indigestion*; but it is useful not only in those forms of the affection which are associated with exhaustion or debility, and which result from previous excesses in eating and drinking or depend upon weakness due to sedentary habits, acute disease, old age, etc. Other forms of gastro-intestinal atony may be associated on the one hand with *constipation*, or on the other with *diarrhœa*, and in either case pure strong coffee in small quantities will often afford relief. In constipation the coffee should be taken early in the morning before the first meal. Partly with a view to promote digestion coffee has been much used during *convalescence* from acute diseases; but in this condition, and also in acute febrile diseases of a *typhoid type*, it had long been employed with advantage before the present rationale of its operation was understood, according to which it restrains tissue-change, and thus becomes a conservator of force. It, indeed, may take the place of alcohol in the adynamic conditions for which that stimulant is prescribed, or may be associated or exhibited alternately with it. It has been found that in *typhus* fever coffee increases the elimination of urea, and in so far purifies the blood without increasing the destructive metamorphosis of tissue, and that it lessens coma and low delirium, which it probably does by contracting the capillaries of the brain. In this and all other typhoidal conditions it appears to act immediately as a stimulant of the heart as well as a conservator of force. It has an advantage over alcohol in that it stimulates and sustains, as well as cheers, without inebriating. Coffee, and also caffeine, have been used in the treatment of *intermittent fever*, and have cured it, as almost everything else has done, occasionally. The power of coffee to prevent and to moderate *alcoholic intoxication* is well known; one may drink more wine while taking coffee than without this association, and actual intoxication is often arrested by a cup of strong coffee. These effects tend to confirm what has been said above of the action of coffee on the brain. *Delirium tremens* is an indirect effect of alcohol, and comes on, it may be, days after intoxication has ceased, and involves an opposite state of the brain—one of anæmia, not of congestion. In this affection coffee is only an adjuvant; what good it does is through its primary stimulant impression upon the nervous system and the stomach, and by its limiting the waste which the exorbitant excitement and muscular effort attendant upon the disease entail. For these purposes it should be given in small and repeated doses. In *opium-narcotism* the condition is much the same as in acute alcoholic intoxication, and in it coffee is equally efficient in preventing coma and its consequences. Experiments upon animals have also shown that coffee and tea are direct physiological antidotes to morphia. Coffee should be given in the manner just recommended, and by the rectum as well as by the mouth, but not to the neglect of other stimulants of the nervous system, such as flagellation and electricity. “Fluid extract of coffee,” and also “strong coffee,” have been used hypodermically in cases of opium-poisoning. According to Litti, coffee is an antidote to *strychnia* in rabbits (*Med. Record*, xxviii. 264). The stimulant action of

strong coffee sometimes prevails against obstinate *hiccup*. The utility of coffee in *spasmodic asthma* has long been established. A competent authority in regard to this disease (Salter) says: "I should think, from my own experience, that coffee relieves asthma in two-thirds of the cases in which it is tried. The relief is very unequal, often merely temporary, and sometimes very slight; sometimes it is complete and permanent." It should be given in a very strong and hot infusion, either an hour in advance of the paroxysm if it occurs periodically, or as soon as the first symptoms are felt. Its mode of action is not accurately known. It must be borne in mind, however, that the attack usually comes on at night, and especially during sleep—that is to say, at a time when all convulsive diseases except hysteria are most apt to break out—and that the action of coffee is directly opposed to sleep; that the paroxysm may be relieved either by stimulants or by sedatives (belladonna, lobelia); and therefore it seems probable that the cure of the attack depends upon the removal of the congestion of the nervous centre which was its immediate cause. A similar mode of action probably explains certain cases in which *chordee* and also *dysury* were terminated by the same means. Some forms of *nervous headache* are apt to be relieved by coffee, by tea, and, as recent observations have shown, by Paraguay tea. It would seem that the most appropriate cases are those in which the face is flushed and other signs exist of cerebral congestion; those, on the other hand, in which the face is pale and the pain appears to be simply neuralgic, and not congestive, are thought to be aggravated by the medicine. Caffeine in two-grain doses is sometimes used, but a well-prepared infusion of coffee is preferable. It has long been known that certain strangulated *hernias* have been reduced under the influence of coffee after the failure of the taxis. In many the reduction was spontaneous, in others easy. They were cases in which the protrusion was recent, and when there was no sign of gangrene or of inflammation in the hernial tumor. The mode of action may be inferred, from what was said above, to be, that coffee excites contraction of the intestinal muscles, by which the gas contained in the loop is expelled, and contraction of the blood-vessels, by which the serous transudation is diminished. In favorable cases these two agencies suffice to lessen the bulk of the tumor and permit its reduction. Desprès has used strong coffee with decided benefit in uterine *hæmorrhage* occurring after delivery and also in the form of *metrorrhagia* (*Bull. de thérap.*, xevi. 201).

In 1725, Zwenger recommended coffee as a remedy for dropsy (*Bull. de thérap.*, ciii. 146). It has been stated above that caffeine is a diuretic. Clinically, it has been proved by Gubler and others to act very promptly in this manner, and to reduce the pulse-rate simultaneously. These effects are ascribed to a direct action upon the nerves of the kidney. In several cases of cardiac *dropsy* "citrate of caffeine" in the dose of 3 grains three times a day promptly produced copious diuresis, even when digitalis had failed or ceased to have any effect (Shapter). The cases most benefited are those in which cardiac irregularity exists as an effect of muscular debility rather than of valvular obstruction. Leech, who found it useful as a diuretic in *cardiac dropsy*, judged that it exerted a direct action upon the kidneys, causing the elimination of water (*Practitioner*, vols. xxiv., xxv.); and Brakenridge, localizing its action still further, pronounced it to be "a stimulant of the renal glandular epithelium, and very slightly, if at all, a vascular diuretic" (*Edinburgh Med. Jour.*, xxvii. 4, 100). That coffee and caffeine are primary and direct stimulants of the whole nervous system seems proved by daily experience, and that their effects are comparable, not to those of digitalis, but rather to the action of alcohol. Unlike digitalis, which affects only certain involuntary muscles, caffeine, like alcohol, stimulates the entire muscular and vascular system. It has been repeatedly said that caffeine and digitalis cannot be substituted therapeutically for one another—that the former acts where the latter ceases to act; and the explanation of this fact resides in their very dissimilar mode of action. When digitalis fails, it is because the heart is either positively or relatively incompetent to propel the blood, and the medicine has no power of strengthening except by tonically contracting it; but coffee or caffeine stimulates the nervous centres which are the source of the heart's power, and temporarily restores the regularity and efficiency of its function, and so permits the removal of the dropsies, etc. which immediately threaten the extinction of life. Cases illustrating this singular rescue from imminent death have been published by Milliken (*Phila. Med. Times*, xii. 344), Brakenridge, Huchard, and others. The explanation affords a satisfactory reason for the failure of caffeine in dropsy that is not due to cardiac disease. (Compare Lépine, Huchard, Dujardin-Beaumetz, *Centralblatt f. Therapie*, i. 229.) Caffeine, and also strong coffee, have been found useful in atonic *diarrhæa*, "in melancholia, in the brain disorders of over-workers, in the sleeplessness and depression of spirits of drunkards, in asthenic

mania" (Shapter. *Times and Gaz.*, July, 1881, p. 33), and as a means of curing the *opium* and the *alcohol habit*. It is probable that the use of coffee in the southern and of alcohol in the northern countries of Europe shows that the one is better adapted to a dry and the other to a damp climate, and also that an intellectual stimulant is more grateful to the excitable nature of Southern, and one that blunts perception to the cooler temperament of Northern, races.

The *dose* of caffeine may be said to range from $\frac{1}{4}$ grain to 2 or 3 grains (Gm. 0.016–0.200) in powder, mixed with sugar. Huchard maintains that the ordinary doses are too small. He begins with 5 or even 10 grains during a day, and then gradually increases the dose until 15 grains, or even two or three times that quantity, are taken in the same space of time. If, like coffee, it sometimes causes uncertainty of sight and gait, nausea, headache, palpitation, etc., the dose must be lessened. Owing to its imperfect solubility it should not be prescribed in pill. The most convenient mode of administering caffeine hypodermically is that proposed by Tanret, who has published the following formula: $\mathcal{R}$. Benzoate of sodium Gm. 3.60; Caffeine Gm. 3; Distilled Water q. s. to make 10 Ccm. Of this solution each Ccm. contains 30 Cg. (5 grains) of caffeine (*Med. Record*, xxiii. 440).

The so-called *valerianate of caffeine* appears in some cases to have been of service in the treatment of *hysterical vomiting* and of *whooping cough*. In the latter disease it was given twice a day in doses of about half a grain (Gm. 0.03) to children of two years and upward.

The Kola or Gourou nut, derived from an African plant, is said to contain a larger proportion of caffeine than the best coffee, besides an appreciable quantity of theobroma and a special form of tannin. It is used by the natives for various diseases of the bowels and liver, and also as a tonic (*Edinb. Med. Jour.*, xxviii. 644).

CAHINCA.—CAHINCA-ROOT.

Radix caincæ, s. *cainanzæ*.—*Cainça*, Fr.; *Caincawurzel*, G.

The root of *Chiococca racemosa*, Jacquin.

Nat. Ord.—Rubiaceæ, Coffeineæ.

Origin.—The plant is a native of Southern Florida, the West Indies, Central America, and a portion of South America. It is a shrub with opposite shining, oval, ovate-oblong, or elliptic leaves, racemes of fragrant yellowish flowers, and small white berries with flattish ovate seeds.

Description.—The woody root exists in pieces 3 to 6 inches (7 to 15 Cm.) long, about $\frac{1}{12}$ to $\frac{1}{4}$ inch (2 to 6 Mm.) thick, more or less bent, externally blackish- or grayish-brown, finely wrinkled longitudinally, with narrow transverse corky ridges and fissures, with a thin brown bark of a resinous lustre internally, and with a whitish wood. It is usually mixed with portions of the lower stem, which are $\frac{1}{2}$ to 1 inch (12 to 25 Mm.) thick, and have deep longitudinal furrows, with intervening rounded often very prominent ridges, produced by separated wood-bundles which have not been developed into separate branches; the porous wood encloses a thin pith and is radiate by medullary rays. The bark has a nauseous, bitter, and acrid taste.

The roots of *Chiococca densifolia*, Martius, and *Ch. anguifuga*, Martius, are of a reddish-brown color, often transversely fissured, and destitute of longitudinal ridges. The shrubs are indigenous to Brazil, and are known there as *cainana* or *caminana*.

Constituents.—The most important constituent of cahinca-root is *cahincin* or *cahincic acid*, which, according to Rochleder (1867), has the composition $C_{40}H_{64}O_{18}$. It exists in the root partly free and partly as a calcium salt (François, Pelletier, and Caventou, 1829), forms white, silky, very bitter needles, is soluble in about 600 parts of cold water and ether, and crystallizes from its solution in hot alcohol. When boiled with hydrochloric acid it is split into sugar and *cahincetin*, $C_{22}H_{34}O_3$, the alcoholic solution of which gelatinizes on the addition of water. Fused together with hydrate of potassium, cahincetin yields butyric acid and *cahincigenin*, $C_{11}H_{24}O_2$. Rochleder and Hlasiwetz (1851) regard the tannin of cahinca-root as being identical with *caffeotannic acid*.

Medical Action and Uses.—When first introduced into American and European medicine cahinca was reputed to be an efficient diuretic, as well as a tonic and laxative. There is no doubt of its diuretic virtues in *dropsy*, independent of acute renal disease. But it is now very rarely employed. It is best administered in a decoction made with 2 drachms (Gm. 8) of the root to a pint of water, or an electuary may be formed with powdered gum and syrup containing about 15 grains (Gm. 1) of the powdered root.

CALAMUS, U. S.—CALAMUS.

Rhizoma calami, P. G.; *Radix calami aromatici*, *Radix acori*.—*Sweet flag*, E.; *Acore vrai*, *Acore odorant*, Fr.; *Kalmuswurzel*, G.

The rhizome of *Acorus Calamus*, Linné. Woodville, *Med. Bot.* 248; Bentley and Trimen, *Med. Plants*, 279.

Nat. Ord.—Araceæ, Acoroideæ.

Origin.—An herbaceous perennial, with leaves resembling those of the flag (iris), and green triangular flowering stems terminating with a cylindrical spadix of small sessile flowers, and a long two-edged bract resembling the leaves. The plant is indigenous to North America and Northern Asia, but has spread throughout Central Asia to India, and throughout Europe to the Pyrenees. In Burmah and Ceylon it is cultivated. It grows in the muddy margins of streams and swamps.

FIG. 44.

Transverse section of rhizome of Calamus; magnified three diameters.

Description.—The rhizome grows to the length of several feet, is horizontal, subcylindrical, about $\frac{3}{4}$ inch (2 Cm.) in diameter; reddish-brown, longitudinally wrinkled, distinctly annulate from the transverse and obliquely-directed leaf-scars, which are crowded near the over-ground stems; in other parts $\frac{3}{8}$ to $\frac{1}{2}$ inch (9 to 12 Mm.) or more distant, and some of them fringed by projecting wood-bundles; the

lower surface of the rhizome shows the circular root-scars arranged in a wavy single or sometimes double line, branching alternately to the right and left. It has a spongy texture, due to numerous air-passages, and breaks with a short corky fracture, showing a white or pale reddish-white color internally. Upon the transverse section a fine darker line (nucleus sheath) separates an elliptical central portion from an outer layer, the latter being in width about one-fifth the diameter of the rhizome. The wood-bundles are irregularly scattered, most numerous within the nucleus sheath: the oil-cells, which become more conspicuous on being moistened by an alkali, are likewise scattered and more numerous in the outer portion.

Calamus has an agreeable aromatic odor, which is best preserved by keeping the rhizome unpeeled, as directed by the present Pharmacopœia. Peeled calamus when fresh is white, but turns pinkish on drying, and is less aromatic and bitter than the unpeeled. It should be collected early in spring, and deprived of the far less aromatic and bitter rootlets, which are 4 to 6 inches (10 to 15 Cm.) long, unbranched, but near the tip beset with soft thin fibres. On drying it loses from 70 to 75 per cent. in weight. It is not subject to adulteration, and cannot easily be confounded with other rhizomes.

Constituents.—The rootlets contain little of the volatile oil; the rhizome yields from $1\frac{1}{2}$ to 2 per cent.: Bartels obtained from the fresh-peeled rhizome $\frac{1}{4}$ per cent., Martius 1 per cent. from the peelings. The yellowish or brown-yellow oil (*Oleum calami*, P. G.) has an agreeable odor, turns red-brown by ferric chloride, and contains, according to A. Kurbatow (1873), a hydrocarbon, $C_{10}H_{16}$, of a terebinthinate odor, boiling at 159° C. (318.2° F.), and yielding with chlorine a crystalline mass which melts at 65° C. (149° F.). The portion boiling at a higher temperature is of a deep-blue color, and not of a constant boiling-point. Faust (1867) named the bitter principle *acovin*. It was obtained from the concentrated decoction by precipitating it successively with alcohol and acetate and subacetate of lead, removing the lead by sulphuretted hydrogen, neutralizing with soda, and agitating with ether, which leaves it as a soft brown-yellowish mass, soluble in ether and alcohol, having a faint alkaline reaction, and being precipitated from its solution in hydrochloric acid by tannin, phospho-molybdate of sodium, and iodo-hydrargyrate of potassium. It contains nitrogen, and when boiled with dilute sulphuric acid or baryta-water yields sugar and a resin-like body. Flückiger obtained a small quantity of crystals from its tannin precipitate by treatment with lead oxide and chloroform. Trommsdorff obtained from the fresh drug 1.6 of starch, 5.5 of gum, 2.3 per cent. of soft resin, and 21 per cent. of cellulose.

Off. Prep.—Extract. calami fluidum, *U. S.*

TINCTURA CALAMI. Digest 1 part of bruised calamus with 5 parts of alcohol spec. grav. .892 for 8 days; express and filter. It has a brownish-yellow color.—*P. G.*

EXTRACTUM CALAMI. Bruised calamus is exhausted by digestion with a mixture of 3 parts of water and 2 parts of alcohol, and the filtered tincture evaporated to the consistence of a thick extract.—*P. G.*

Physiological Action and Medical Uses.—Calamus excites a sense of warmth in the stomach, promotes the appetite, and improves the digestion. It is said to quicken the pulse and increase the secretion of urine and perspiration. In excessive doses it may cause headache. It is added to bitter tonic infusions in atonic *dyspepsia* and other disorders producing abdominal flatulence. It may be used for the relief of flatulent *colic* and as a very mild stimulant in some cases of the *typhoid condition*. It is often eaten prepared with sugar as a conserve, and it may be habitually chewed to relieve slight dyspeptic disorder. An infusion made with an ounce (Gm. 32) of calamus and a pint of hot water may be prescribed in the dose of a wine-glassful.

CALCI BROMIDUM, *U. S.*—BROMIDE OF CALCIUM.

Calcium bromatum.—*Bromure de calcium*, Fr.; *Bromcalcium*, *Calciumbromid*, G.

Formula CaBr_2 . Molecular weight 199.6.

Preparation.—Bromide of calcium is readily prepared by dissolving pure calcium carbonate in hydrobromic acid and evaporating the solution. Bödeker has used a method which was described by Faust (1867), and is based upon the decomposition of bromide of sulphur, SBr_6 , by lime, whereby bromide and sulphate of calcium are formed; $\text{SBr}_6 + 4\text{CaH}_2\text{O}_2$ yields $3\text{CaBr}_2 + \text{CaSO}_4 + 4\text{H}_2\text{O}$. 20 parts of sulphur are dissolved in 240 parts of bromine (300 parts are required by calculation), and the solution added to thin milk of lime, which contains 140 parts of pure lime. After the mixture has become colorless the liquid is filtered, treated with carbonic acid gas, and heated, to remove excess of lime: the filtrate is concentrated, mixed with twice its bulk of alcohol to precipitate calcium sulphate, is again filtered, and evaporated.

Properties.—Thus obtained, bromide of calcium is a whitish, granular, or pulverulent, neutral, deliquescent salt having a pungent bitter and saline taste. It is freely soluble in alcohol (1 part, *U. S.*) and water, the latter solution yielding with difficulty colorless needles. According to Kremers (1857, 1858), 1 part of the salt dissolves at 0°C . (32°F .) in .80 parts, at 20°C . (68°F .) in .70 parts, at 40°C . (104°F .) in .47 parts, and at the boiling-point 105°C . (221°F .) in .32 parts of water, and solutions having at 19.5°C . (67°F .) the specific gravity

	1.044	1.089	1.139	1.194	1.252	1.315	1.385	1.461	1.594	1.641	
contain	5	10	15	20	25	30	35	40	45	50	per cent. CaBr_2 .

The salt melts at a red heat, giving off bromine; treated with strong sulphuric acid, hydrobromic acid is evolved, afterward bromine and sulphurous acid gas. The aqueous solution yields with ammonium oxalate a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid; with nitrate of silver, a curdy precipitate insoluble in nitric acid and in diluted ammonia-water; and with a few drops of chlorine-water liberates bromine, which dissolves in carbon disulphide with a yellow or brown-yellow color free from violet tint.

The solution left in contact with lime forms an oxybromide of calcium, which has a strong alkaline reaction, and on evaporation is left behind as a very white salt.

Tests.—The neutral reaction of the salt and its ready solubility in water and alcohol exclude most impurities. If diluted sulphuric acid be dropped upon the salt, the latter should not at once assume a yellow color (absence of bromate and nitrate). If 1 Gm. of the salt be dissolved in 10 Cem. of water, some gelatinized starch added, and then a few drops of chlorine-water carefully poured on top, no blue zone should make its appearance at the line of contact of the two liquids (iodide). On adding to 1 Gm. of the salt dissolved in 20 Cem. of water 5 or 6 drops of test solution of nitrate of barium no immediate cloudiness or precipitate should make its appearance (sulphate). If a portion of the salt be precipitated with an excess of nitrate of silver, the washed precipitate for some time shaken with a cold saturated solution of carbonate of ammonium, and the decanted and filtered liquid supersaturated with nitric acid, (not more than a faint cloudiness, insufficient to produce a precipitate, should appear (limit of chloride). On adding to the aqueous solution, first, chloride of ammonium, then test solution of carbonate of

ammonium and water of ammonia in slight excess, and gently warming, the filtrate separated from the resulting precipitate should not be rendered more than faintly turbid by test solution of phosphate of sodium (limit of magnesium). 1 Gm. of the dry salt when completely precipitated by nitrate of silver yields, if perfectly pure, 1.878 Gm. of dry bromide of silver."—*U. S.*

Medical Action and Uses.—In 1871 this salt was stated by Dr. Hammond to produce the characteristic effects of the bromides more promptly than the analogous compounds, and also to induce sleep where they failed to do so. He regarded it as peculiarly appropriate for relieving the *insomnia* caused by mental labor or excitement, and the exhausted and irritable states of the nervous system met with in *hysterical* women, and accompanied by headache, vertigo, insomnia, and extreme mental excitability. He also found that it cured *epilepsy* in very young infants when bromide of potassium failed. The best mode of administering it is said to be according to the following formula: *R.* Calcii bromid. $\mathfrak{z}$ j; Syrupi calcis lactophos. $\mathfrak{f}\mathfrak{z}\mathfrak{i}\mathfrak{v}$.—*M. S.*—A teaspoonful three times a day in a little water in epileptic cases. As a hypnotic for adults the dose is from 20 to 30 grains (Gm. 1.30 to 2.00).

It has been objected to this as well as to the other bromine salts that their sedative action is due not to the bromine they contain, but to their alkaline or earthy bases. This strange notion is sufficiently condemned by the fact that uncombined bromohydric acid produces the same effects as its salts.

Iodobromide of calcium is reported to have maintained in quiescence the distressing symptoms of a case of *exophthalmic goitre*, and at last reduced the thyroid gland to its natural size.

CALCII CARBONAS PRÆCIPITATUS, *U. S.*—PRECIPITATED CARBONATE OF CALCIUM.

Calcis carbonas præcipitata, Br.; *Calcium carbonicum præcipitatum*, P. G.; *Calcaria carbonica præcipitata*, *Carbonas calcicus præcipitatus*, *Creta præcipitata*.—*Precipitated carbonate of lime*, E.; *Carbonate de chaux précipité*, *Craie précipitée*, Fr.; *Calciumkarbonat*, *Præcipitirter kohlen-saurer Kalk*, G.

Formula CaCO_3 . Molecular weight 100.

Preparation.—Take of Chloride of Calcium 5 ounces; Carbonate of Soda 13 ounces; boiling Distilled Water a sufficiency. Dissolve the chloride of calcium and carbonate of soda each in 2 pints of the water; mix the two solutions and allow the precipitate to subside. Collect this on a calico filter, wash it with boiling distilled water until the washings cease to give a precipitate with nitrate of silver, and dry the product at the temperature of 100°C . (212°F).—*Br.*

In this process a mutual decomposition of calcium chloride and sodium carbonate takes place, resulting in the formation of sodium chloride, which remains in solution, and calcium carbonate, which precipitates. The decomposition is illustrated by the equation $\text{CaCl}_2 + \text{Na}_2\text{CO}_3 = 2\text{NaCl} + \text{CaCO}_3$. The precipitate retains, even after prolonged washing, a small portion of sodium salt; made with ammonium carbonate, it is much more readily freed from the latter by washing. If carbonate of calcium is precipitated in the cold, it is flocculent and quite voluminous, and with difficulty deprived of the mother-liquor by washing; hence it is advisable to heat the solutions before mixing them.

Properties.—Thus prepared, it is a white, impalpable, inodorous, and tasteless powder consisting of microscopic rhombohedral crystals, but entirely free from grittiness. It has the specific gravity 2.72, is without action upon moistened test-paper, and is not altered in the air, but above 400°C . (752°F .) begins to evolve carbonic acid gas, and at a red heat is entirely converted into calcium oxide. The salt is completely insoluble in water and alcohol, but dissolves without residue in dilute hydrochloric, nitric, or acetic acid, carbonic acid gas being copiously given off. Such solutions, if necessary neutralized with ammonia, yield with oxalate of ammonium a white precipitate of oxalate of calcium, which is insoluble in acetic acid, but dissolves in hydrochloric acid.

Tests.—"On adding to the solution in acetic acid first, chloride of ammonium, then test solution of carbonate of ammonium and water of ammonia in slight excess, and gently warming, the filtrate separated from the resulting precipitate should not be rendered more than faintly turbid by test solution of phosphate of sodium (limit of magnesium). A solution of the salt in hydrochloric acid, freed from carbonic acid gas by heat, should not be rendered turbid when supersaturated with water of ammonia (absence of aluminium, iron, or phosphate)."—*U. S.* This ammoniacal liquid on being heated and precipitated

by ammonium carbonate should yield a filtrate which, on being evaporated to dryness and ignited, should leave not more than a trace of residue (magnesium and sodium salt).

A substitution of calcium sulphate for the carbonate, wholly or partly, has been occasionally observed; this will not readily dissolve in diluted hydrochloric acid, with little or no effervescence; boiled with distilled water and allowed to cool, then filtered, a liquid will be obtained giving a white precipitate with barium chloride.

Off. Prep.—Trochisci bismuthi, *Br.*

Medical Action and Uses.—Chalk is astringent and antacid. In the form of prepared chalk it is much used as a dusting powder by females who have a coarse and greasy skin, and also to promote the healing of slight *abrasions, burns, and scalds*, certain cutaneous eruptions, etc. It is used in an ointment as a dressing for *ulcers* with flabby granulations and a profuse discharge. It is administered internally to check *diarrhœa*, especially when due to cold and accompanied with acidity, as indicated by sour eructations or breath, colic, flatulence, and acid and greenish discharges. If there is any reason to suppose that the alimentary canal contains undigested food, a mild laxative (magnesia) should first be given. Chalk is generally prescribed to relieve diarrhœa in the form of the official chalk mixture, with the addition of an astringent, as tincture of catechu, of kino, etc., and a few drops of laudanum. There is no better medicine in the incipient stages of epidemic *cholera*. The *dose* of prepared chalk is from 5 to 60 grains (Gm. 0.30–4.00) or more, suspended in thin mucilage.

CALCI CHLORIDUM, U. S., *Br.*—CHLORIDE OF CALCIUM.

Calcium chloratum, Calcaria muriatica, Chloridum calcicum.—*Chlorure de calcium, Fr.; Chlorcalcium, Calciumchlorid, G.*

Formula CaCl_2 . Molecular weight 110.8.

Chloride of calcium deprived of its water by fusion at a low red heat. It should be preserved in a well-stopped bottle.

Preparation.—This compound is a by-product in many chemical processes, among others in that for solution of ammonia. It may be formed by neutralizing hydrochloric acid with marble or other calcium carbonate; $\text{CaCO}_3 + 2\text{HCl}$ yields $\text{CaCl}_2 + (\text{CO}_2 + \text{H}_2\text{O})$. Iron being usually contained in these native carbonates, it is removed by digesting the solution with chlorinated lime and slaked lime, by which the iron is first converted into ferric chloride and then precipitated as ferric hydrate. The filtrate, which will be found to have an alkaline reaction, is neutralized with hydrochloric acid, evaporated, and dried at a temperature of 200°C. (392°F.). The direction of the U. S. P. to heat to low redness is an unnecessary complication, since the whole of the water of crystallization is expelled at 200°C. ; the British Pharmacopœia very properly directs the final drying of the salt at about 204.5°C. (400°F.).

Properties.—Calcium chloride is in white, dry, but very deliquescent inodorous masses, and has a hot, saline, and bitterish sharp taste. The U. S. Pharmacopœia describes it as colorless, slightly translucent, hard, and friable masses, in which condition it is obtained by heating the salt to fusion at a red heat. Since in driving off the last portions of water a small quantity of chlorine is expelled as hydrochloric acid, the anhydrous salt has usually a faint alkaline reaction, which is increased at a red heat. According to Kremers (1858), 1 part of the anhydrous salt dissolves at 10°C. (50°F.) in 1.58 parts, at 15°C. (59°F.) in 1.46 parts, at 20°C. (68°F.) in 1.35 parts, at 40°C. (104°F.) in .83 part, at 60°C. (140°F.) in .72 part of water; the solution, saturated at 15°C. (59°F.), has the specific gravity 1.41104. The concentrated solutions, exposed to a low temperature, deposit transparent crystals of the salt containing $6\text{H}_2\text{O}$, and these melt in the neighborhood of 30°C. (86°F.); when evaporated to dryness at a temperature not exceeding 150°C. (302°F.) a crystalline powder, $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, is obtained, which on being mixed with two-thirds its weight of snow produces a temperature of -45°C. (-49°F.). The anhydrous salt dissolves in about 8 parts of cold absolute alcohol, and at 78.3°C. (174°F.) in 1.43 parts; it is more freely soluble in alcohol containing water. These solutions are precipitated by an excess of ether, and on concentration and cooling yield soft white crystals of calcium chloride, combined with alcohol ($2\text{C}_2\text{H}_5\text{O}$) or with alcohol and water. The aqueous solution yields with ammonium oxalate a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid, and with silver nitrate a white precipitate readily soluble in ammonia and reprecipitated by nitric acid.

Tests.—"The dilute aqueous solution should not be precipitated by water of ammonia (aluminium, iron, etc.), nor by test solution of chloride of barium (sulphate). On adding

to the aqueous solution, first, chloride of ammonium, then test solution of carbonate of ammonium and water of ammonia in slight excess, and gently warming, the filtrate separated from the resulting precipitate should not be rendered more than faintly turbid by test solution of phosphate of sodium (limit of magnesium).”—*U. S.* The aqueous solution should not be precipitated by lime-water (absence of soluble carbonate), by solution of calcium sulphate (absence of barium), or by hydrosulphuric acid, neither before nor after the addition of ammonia (absence of metals).

Pharmaceutical Uses.—(Chloride of calcium is used for the drying of gases and certain liquids and in the preparation of various calcium salts. For the latter purpose it is directed only in the process for *Calc. carbonas præcipitata*. A solution of the crystalline salt (mentioned above) in $1\frac{1}{2}$ parts of distilled water constituted the *Liquor calcii chloridi*, *U. S. P.* 1870.

Physiological Action and Medical Uses.—(Chloride of calcium is an active irritant, and in excessive doses may occasion gastro-intestinal inflammation. In medicinal doses it is supposed to have a special action upon the glandular system, increasing secretion, removing infarctions, etc. It has been used very successfully to reduce *scrofulous swellings* of the external lymphatic glands, of the mesenteric glands, etc., and in *strumous diseases of the skin*, particularly *lupus*. In the latter cases it should be associated with iodine, applied locally. It is also said to exhibit peculiar virtues in the *dyspeptic* disorders to which scrofulous children are subject, and which are popularly supposed to be of verminous origin, such as restless sleep, capricious appetite, irregular stools, foul breath, and enlarged tonsils. (For full details see W. Begbie, *Works*, Sydenham Soc. ed., p. 307.) Physicians of authority have affirmed its curative power in cases of *uterine* and *ovarian tumors*. The only tumors which contract under this or any other medicinal treatment are the so-called muscular tumors, which may be reduced by the loss of their liquid constituents. The use of the medicine is not unattended with risk. If persisted in for a length of time it is apt, according to Wells, to bring about calcareous degeneration of the arteries generally. Whatever action it may possess in arresting the growth of fibroids probably depends upon this property. *Dose*, from 10 to 20 grains (Gm. 0.60–1.30), taken in milk or dissolved in a large quantity of water. The old “solution of muriate of lime” (*Ph. Edin.*) contained 8 ounces of the crystallized salt in 12 fluidounces of water. *Dose* for an adult, from 20 to 50 minims. in water or milk. A syrup has been prepared which contains 5 ounces of the crystallized salt in 12 fluidounces of the excipient. *Dose*, a teaspoonful.

CALCI HYPOPHOSPHIS, *U. S.*—HYPOPHOSPHITE OF CALCIUM.

Calcis hypophosphis, Br. Add.: *Calcium hypophosphorozum*, *Calcarea hypophosphorosa*, *Hypophosphis calcicus*.—*Hypophosphite of lime*, E.; *Hypophosphite de chaux*, Fr.; *Calcium-hypophosphit*, *Unterphosphorigsaurer Kalk*, G.

Formula $\text{Ca}_2\text{PH}_2\text{O}_2$ or $\text{CaH}_4(\text{PO}_2)_2$. Molecular weight 170.

Preparation.—Hypophosphite of calcium is obtained by heating phosphorus with milk of lime, inflammable phosphoretted hydrogen being given off—namely, $3(\text{Ca}2\text{HO}) + 6\text{H}_2\text{O} + 4\text{P}_2$ yields $3(\text{Ca}_2\text{PH}_2\text{O}_2) + 2\text{PH}_3$. Procter (1858) uses a deep boiler, in which a uniform milk is made with 4 pounds of burned lime and 5 gallons of water; 1 pound of phosphorus is added, and the whole boiled, boiling water being added from time to time to preserve the measure, until the phosphorus has been all oxidized and the strong odor of phosphoretted hydrogen has disappeared. The mixture is filtered, the residue washed with water, the mixed filtrates evaporated to 6 pints, filtered from the hydrate and carbonate of calcium, and again evaporated and crystallized or granulated. Nearly half the phosphorus is oxidized to phosphoric acid, probably by the decomposition of water, since the escaping gas contains free hydrogen (Wurtz) and remains with the excess of lime as calcium phosphate. E. Scheffer (1858) succeeded in avoiding much of this loss by using phosphorus which had been previously burned under water by passing atmospheric air into it, whereby it assumed a spongy appearance. It unites then with the lime even at the ordinary temperature, but more readily at 55°C . (about 130°F .), and very little spontaneously inflammable gas is generated. The salt is prepared on the large scale by adding granulated phosphorus to milk of lime and exposing the mixture to the air, and agitating frequently until the phosphorus has disappeared. A small portion of phosphoretted hydrogen is evolved (Gmelin-Kraut's *Chemie*). It is well to precipitate the dissolved lime by passing carbonic acid gas through the warm filtrate and by filtering again. The observation previously made by Wurtz, that hypophosphites boiled with an excess of

alkali are decomposed into hydrogen and phosphite or phosphate, has been recently confirmed by W. F. Short (1882) for the calcium salt prepared by boiling with excess of lime.

Properties.—Hypophosphite of calcium crystallizes in transparent, thin, flexible scales composed of flat monoclinic prisms, but is usually met with as a white crystalline powder with a pearly lustre, of a neutral or slightly alkaline reaction, inodorous, and of a bitter, nauseous taste. In the dry state it is permanent in the air, but when dissolved in water it is gradually oxidized to calcium phosphate. Heated to redness in a retort, it decrepitates, evolves water, spontaneously inflammable phosphoretted hydrogen, and a little phosphorus, and leaves nearly 80 per cent. of a reddish residue containing a little amorphous phosphorus and calcium pyrophosphate. The salt dissolves in 6 parts (6.8 parts, *U. S.*) of cold and in a slightly less amount of boiling water; it is insoluble in strong and but slightly soluble in dilute alcohol (*H. Rose*). The solution yields white precipitates with silver nitrate and with mercuric chloride, both turning dark when heated, from a reduction to the metallic state. Metallic gold is precipitated from the chloride, and the soluble copper salts yield, with the solution, particularly on heating, metallic copper. Oxalate of ammonium produces in the solution a white precipitate which is insoluble in acetic acid, but dissolves in hydrochloric acid.

Tests.—Its complete solubility in water proves the absence of phosphate and carbonate of calcium. The solution should not be precipitated by lead acetate (absence of soluble phosphate, etc.) or by acidulated barium chloride (absence of sulphate). It should give a blue precipitate with ammonium molybdate, the precipitate appearing green if phosphate is present from the admixture with yellow phosphomolybdate. "On adding to the aqueous solution, first, chloride of ammonium, then test solution of carbonate of ammonium and water of ammonia in slight excess, and gently warming, the filtrate separated from the resulting precipitate should not be rendered more than faintly turbid by test solution of phosphate of sodium (limit of magnesium)." — *U. S.*

Off Prep.—Syrupus hypophosphitum, *U. S.*

Pharmaceutical Uses.—**SYRUPUS CALCII HYPOPHOSPHITIS.** Hypophosphite of Calcium 1 ounce; Water $9\frac{1}{2}$ fluidounces; Sugar 12 ounces; Essence of Vanilla $\frac{1}{2}$ fluidounce. Dissolve and mix (*Procter*).

Medical Action and Uses.—On theoretical grounds the combinations of phosphorus with lime have been supposed to possess a power of stimulating and regenerating the nervous system and those tissues which contain phosphorus and lime. The experiments of *Perl* (*Virchow's Archiv*, lxxiv. 54) led him to conclude that the soluble salts of lime are in a slight degree absorbable, and therefore capable to that extent of acting therapeutically when the normal lime compounds of the body are deficient. According to *Dysart*, the lacto-phosphate is the only salt of lime that is readily appropriated by the economy (*Practitioner*, xxii. 375). These views have led to the use of the lime salts in *anaemia*, *scrofula*, *caries*, *tuberculosis*, and other cachectic conditions; in *chlorosis* and *menorrhagia*; in *fractures* uniting slowly or imperfectly; in *rickets* and in *Pott's disease*; and in various chronic *profluvia* connected with a feeble and often strumous state of the system. The claims of these preparations, independently of other and more efficient medicines (iron, cod-liver oil) and hygienic influences, consist largely of assertion without evidence, and are too slender to be seriously entertained. Nevertheless, as the preparations of lime in question are innocuous, there is no reason why the degree of benefit they confer, however slight, should not be taken advantage of in the various cachexiae mentioned. *Dose*, 5 or 6 grains (*Gm.* 0.30–0.40) or more, at meal-times. The syrup of the hypophosphate of calcium may be used in doses of a fluidrachm (*Gm.* 4).

CALCII IODAS.—IODATE OF CALCIUM.

Iodate de chaux, *Fr.*; *Jodsaurer Kalk*, *G.*

Formula $\text{Ca}_2\text{IO}_3 \cdot 6\text{H}_2\text{O}$. Molecular weight 497.2.

Preparation.—The following process was proposed by *W. Flight* (1864): An alcoholic solution of iodine is gradually mixed with an excess of a filtered aqueous solution of chlorinated lime, care being taken to prevent the increase of temperature, so that the formation of chloride of iodine shall not be permitted. The chlorinated lime oxidizes the iodine, iodate of calcium being precipitated, while chloride of calcium and hydrochloric acid remain in solution; $5\text{CaCl}_2\text{O}_2 + 2\text{I}_2 + 2\text{H}_2\text{O}$ yields $2\text{CaI}_2\text{O}_6 + 3\text{CaCl}_2 + 4\text{HCl}$. *Reichardt* (1874) directs the use of iodine with an excess of chlorinated lime diffused in water. After decolorization the mixture is slightly acidulated with hydrochloric acid, heated to boiling, and the filtered solution crystallized.

Properties.—Iodate of calcium crystallizes from water in flat, colorless, shining needles, which are slowly efflorescent on exposure, require at 15° C. (59° F.) about 300 parts of water for solution, and are nearly insoluble in alcohol. The aqueous solution yields a white precipitate with oxalate of ammonium, and liberates iodine on the addition of sulphurous acid.

CALCI IODIDUM.—IODIDE OF CALCIUM.

Calcium iodatum.—*Iodure de calcium*, Fr.; *Jodecalcium*, *Calciumjodid*, G.

Formula CaI_2 . Molecular weight 293.2.

Preparation.—The salt is obtained on dissolving slaked lime in hydriodic acid and evaporating; or, 3 parts of iodine are digested with sufficient iron and water until a green solution of ferrous iodide is obtained. The liquid is filtered and mixed with 1 part of iodine, and after this has been dissolved it is boiled with milk of lime prepared with 1 part of burnt lime, until the iron has been precipitated; the liquid is then filtered and evaporated.

Properties.—Iodide of calcium is a white salt which crystallizes with difficulty in pearly scales. It is freely soluble in alcohol and water, and is very deliquescent. 100 parts of water dissolve at 0° C. (32° F.) 192, at 20° C. (68° F.) 204, and at 92° C. (197.6° F.) 435 parts of the salt. On exposure to the air the solution is partly decomposed, carbonate of calcium being precipitated. The solution yields a white precipitate with oxalate of ammonium, and a bright red one with corrosive sublimate.

Tests.—On mixing the solution with sulphurous acid and sulphate of copper in excess and heating the mixture, a grayish precipitate of cuprous iodide is produced, and the filtrate yields no precipitate on the addition of nitrate of silver (absence of chloride and bromide).

Medical Action and Uses.—Experiments seem to show that this salt arrests putrefactive fermentation, deodorizes fecal matter, and acts as an irritant upon the living tissues. Given internally, in doses of from 1 to 3 grains (Gm. 0.06–0.20) three times a day, it is alleged to arrest *erysipelas*, diminish and deodorize *suppurative discharges*, and promote the cure of *scrofulous ulceration*. These statements call for confirmation, and even more so its claims to extraordinary efficacy in pulmonary *phthisis*.

CALCI PHOSPHAS PRÆCIPITATUS, U. S.—PRECIPITATED PHOSPHATE OF CALCIUM.

Calcis phosphas, Br.; *Calcium phosphoricum*, P. G.; *Calcarea phosphorica*, *Phosphas calcicus præcipitatus*.—*Precipitated phosphate of lime*, E.; *Phosphate de chaux hydraté*, Fr.; *Calciumphosphat*, *Phosphorsaure Kalkerde*, G.

Formula $\text{Ca}_3\text{P}_2\text{O}_8$. Molecular weight 310.

Preparation.—Take of Bone-ash 4 ounces; Hydrochloric Acid 6 fluidounces; Water 2 pints; Solution of Ammonia 12 fluidounces or a sufficiency; Distilled water a sufficiency. Digest the bone-ash in the hydrochloric acid, diluted with a pint of water, until it is dissolved. Filter the solution if necessary; add the remainder of the water, and afterward the solution of ammonia, until the mixture acquires an alkaline reaction; and, having collected the precipitate on a calico filter, wash it with boiling distilled water as long as the liquid which passes through occasions a precipitate when dropped into solution of nitrate of silver acidulated with nitric acid. Dry the washed product at a temperature not exceeding 100° C. (212° F.).—Br.

The process of the U. S. P. 1870 was identical with the above. By dissolving the bone-earth in hydrochloric acid, acid calcium phosphate, $\text{CaH}_2\text{P}_2\text{O}_8$, and calcium chloride, CaCl_2 , are formed; on the addition of ammonia the result is ammonium chloride, water, and tricalcium phosphate, the latter of which precipitates; $\text{CaH}_2\text{P}_2\text{O}_8 + 2\text{CaCl}_2 + 4\text{NH}_4\text{HO}$ yields $4\text{NH}_4\text{Cl} + 4\text{H}_2\text{O} + \text{Ca}_3\text{P}_2\text{O}_8$. The ammonium chloride is removed by washing with water. If the precipitation is effected in the cold the calcium phosphate is very voluminous and the washing is quite difficult. The calcium phosphate of the German Pharmacopœia is prepared by precipitating a solution of calcium chloride with sodium phosphate, has the composition $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$, is more readily soluble than the above salt, and when heated to redness loses 26 per cent. of water.

Properties and Tests.—This preparation is often called *bone phosphate* to distinguish it from other calcium phosphates; it forms a light white, amorphous, permanent powder, which at a strong red heat melts without decomposition, and on cooling yields a

porcelain-like mass. When fused with sodium carbonate or digested with a solution of this salt, it is partly decomposed, with the formation of calcium carbonate. It is insoluble in water and other simple solvents; but it is somewhat soluble in solutions of sodium chloride and other neutral alkali salts. Continued boiling with water induces decomposition, with the formation of basic phosphate, $\text{Ca}_3(\text{PO}_4)_3\text{OH}$, and of hydrophosphate, CaHPO_4 . Calcium phosphate dissolves without effervescence in dilute hydrochloric acid (absence of carbonate); also in dilute nitric and acetic acids, and even in carbonic acid water. The acetic acid solution, which is best obtained by adding to the nitric acid solution an excess of sodium acetate (a white precipitate indicates ferric phosphate), yields a white precipitate with ammonium oxalate (presence of calcium), a white one with ferric chloride, and a yellow one with ammonio-nitrate of silver (presence of phosphate). The solution of 10 Gm. of the phosphate in hydrochloric acid yields with ammonia a white precipitate insoluble in boiling solution of potassa (alumina would be dissolved), and when washed and dried weighs 10 Gm. The phosphate contains small quantities of ammonio-phosphate of magnesium and calcium fluoride, derived from the bones.

CALCIUM PHOSPHORICUM CRUDUM, *P. G.*, is a white or grayish-white powder which dissolves almost completely in dilute hydrochloric acid, with slight effervescence. It is probably *bone-ash*.

Off. Prep.—Pulvis antimonialis, *U. S.*, *Br.*; Syrupus calcii lactophosphatis, *U. S.*

Pharmaceutical Uses.—SYRUPUS CALCII PHOSPHATIS. 1 troyounce of phosphate of calcium dissolved with sufficient hydrochloric (or preferably phosphoric) acid, avoiding excess of acid, and sufficient syrup to make 1 pint (Wiegand, 1854). The syrups of chlorhydrophosphate and of acid phosphate of calcium, as used in France, are little more than one-fourth the strength of the preceding.

SYRUPUS CALCII LACTOPHOSPHATIS. The French formula (1877) is as follows: 12.5 Gm. of calcium phosphate are dissolved in sufficient (about 14 Gm.) of concentrated lactic acid and 340 Gm. of water; 630 Gm. of sugar are dissolved in the liquid, and 10 Gm. of essence of lemon added. In the United States 4 drachms of calcium phosphate and sufficient lactic acid have been used for making 1 pint of syrup.

Medical Action and Uses.—If this compound and its preparations possess medicinal virtues, they are chiefly those of the hypophosphite of lime, which is treated of elsewhere. They have been used with reputed advantage in *mollities ossium*, and also to promote the consolidation of *fractures* in which the formation of callus is slow or imperfect. The *dose* of the phosphate is from 10 to 30 grains (Gm. 0.60–1.60), and may conveniently be given in carbonic acid water.

CALCII SULPHAS.—SULPHATE OF CALCIUM.

Gypsum, *E.*; *Sulfate de chaux*, *Gypse*, *Fr.*; *Calciumsulfat*, *Schwefelsaurer Kalk*, *Gyps*, *G.* Formula $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$. Molecular weight 172.

Origin.—This compound is met with in nature in the form of transparent prisms known as *selenite*, and in semi-opaque or opaque masses which are called *alabaster* and *gypsum*. On adding sulphuric acid or a sulphate to a solution of a calcium salt the same compound is precipitated.

Properties.—Sulphate of calcium is white, crystalline or amorphous, insoluble in alcohol, soluble in about 380 parts of cold water and in 450 parts of boiling water: an aqueous solution, saturated at the ordinary temperature, becomes turbid on being heated to boiling. When heated to between 100° and 200° C. (212° and 392° F.) the salt becomes anhydrous.

CALCII SULPHAS USTUS, s. Calcium sulfuricum ustum, *P. G.*—Plaster of Paris, *E.*; Plâtre, *Fr.*; Gebrannter Gyps, *G.*—It is obtained from native gypsum in the manner indicated above, and after grinding constitutes a white amorphous powder, which when made into a paste with water combines with it and solidifies in a few minutes, at the same time slightly expanding in volume. Gypsum which has been dehydrated at 400° C. (752° F.) or at a higher temperature is *overburnt*, and does not exhibit the property of rapidly recombining with water. Plaster of Paris should be preserved in well-closed vessels, to prevent the gradual absorption of moisture from the atmosphere.

Surgical Uses.—Plaster of Paris is used for making casts of deformities and surgical injuries, and as one of the articles adapted for applying the so-called immovable apparatus intended to retain broken bones in a fixed position. "A roller of coarse, soft muslin must have dry plaster of Paris thoroughly rubbed into its meshes; some cold water is then to be poured upon either end of it, so as to moisten it through. A dry

roller having been previously applied to the limb, the wetted plaster bandage must be smoothly rolled upon it, the surgeon taking care that no reverses are made. . . . It hardens in the course of a few minutes, and as it dries forms a solid, hard, and light casing to the limb. It has the advantage over the starch apparatus of being lighter, and especially of drying and hardening quickly" (Erichsen). Some surgeons recommend "crinoline," and others "cheese-cloth," in preference to muslin as a material for the bandages, on account of the larger meshes of their web; and it is suggested to impregnate the fabric with the powdered plaster of Paris by passing it through a box containing this substance. To render the plaster less brittle it is sometimes mixed with mucilage, which, however, causes it to dry more slowly. The bandage may be converted into a jacket by cutting it, when dry, down the middle of the front and finishing the edges with eyelet-holes and lacings. (See *Med. Record*, xvi. 487.)

This bandage has been regarded as peculiarly suited to the treatment of simple, compound, and comminuted *fractures* of the limbs and ribs, and of Pott's *disease of the spine*. It is regarded by surgeons as the best form of immovable apparatus, provided that it be judiciously and skilfully applied; but some object that, owing to the concealment of the seat of injury, cures with shortening, deformity, etc. are more common with the use of the immovable than with other apparatus. In treating angular curvature of the spine the patient is partially suspended by the head and shoulders, or is lying prone in a canvas hammock, while the bandage is applied. (For further information compare *Med. Record*, xxi. 11; *Med. Chir. Trans.*, lxiv. 295.)

CALCII SULPHIS.—SULPHITE OF CALCIUM.

Sulfite de chaux, Fr.; *Schweifigsaurer Kalk*, G.

Formula $\text{CaSO}_3 \cdot 2\text{H}_2\text{O}$. Molecular weight 156.

Preparation.—4 parts of slaked lime are intimately mixed with 1 part of water; the mixture is spread out in thin layers, and sulphurous acid gas passed into the vessel or chamber as long as it is absorbed; or, the gas is passed into milk of lime and the resulting precipitate dried.

Properties.—Sulphite of calcium is a white powder requiring 800 parts of cold water for solution; it dissolves readily in aqueous sulphurous acid, and crystallizes from this solution in hexagonal prisms. It has a slight sulphurous taste, and on exposure is gradually converted into sulphate of calcium.

Medical Action and Uses.—The local action of this sulphite appears to be very slight, since when administered to dogs in very large doses it does not occasion any signs of gastro-intestinal irritation. This fact is referable, in part at least, to the great insolubility of the compound. It appears to be absorbed and excreted without change in the urine. It limits *fermentation* and *putrefaction* in the digestive organs, like other compounds of sulphurous and hyposulphurous acids (see *ACIDUM SULPHUROSUM*), and may be applied externally for the same purposes and to stimulate indolent *ulcers*, etc. The very large quantities which are considered necessary for securing its effects render its internal administration as difficult as it is indeed superfluous, considering the number of soluble sulphites and hyposulphites available.

CALENDULA, U. S.—CALENDULA.

Marigold, E.; *Sauçi*, *Fleur de tous les mois*, Fr.; *Ringelblume*, *Todtenblume*, G.

The fresh flowering herb of *Calendula officinalis*, Linné.

Nat. Ord.—Compositæ, Cynarææ.

Description.—The garden marigold is an annual plant, a native of Southern Europe and the Levant, and is frequently cultivated for ornament. It has a spreading somewhat angular and roughish-hairy stem a foot or two (.3 to .6 M.) high, and alternate, sessile, rather fleshy, hairy, and entire or few-toothed leaves, of which the lower ones are spatulate or obovate, and the upper ones varying between oblanceolate and lance-oblong. The flower-heads are terminal, about 2 inches (5 Cm.) broad, have a flattish, hemispherical involucre, with two rows of nearly equal linear-lanceolate scales, and a flat receptacle without chaff. The ray-florets are in one or several rows, pistillate, strap-shaped, about $\frac{3}{4}$ inch (19 Mm.) long, $\frac{1}{4}$ inch (3 Mm.) wide, veined, three-toothed at the apex, and vary in color from light-yellow to orange. The numerous disk-florets are tubular, five-cleft, yellow, staminate, and barren. The akenes are strongly incurved or coiled, and more or less muricate, those of the outer row distinctly winged, those of the inner rows with slight or no wings. The

fresh plant has a rather strong and heavy somewhat narcotic odor and a bitter somewhat saline taste. After drying, the plant has but little odor and a weaker taste.

The dried ray-florets, and occasionally also the flower-heads, are sometimes found in commerce; they have the characters described above. On exposure to the sunlight the yellow color of the florets is changed to a whitish tint.

Substitution.—In 1867 we called attention to the fact that the flower-heads of *Tagetes erecta*, *Linne*, were sold as calendula, and we believe that much of the *fluid extract of calendula* at present in the market is really obtained from the species named and from *Tag. patula*, *Linne*. These two plants are indigenous to Mexico and tropical America, but are often cultivated under the names of *French* or *African marigold*. They have pinnatifid leaves and showy flowers, with the scales of the involucre united to form a tube, the receptacle naked, and the ray-florets broadly ligulate, toothed, light or deep orange-colored, sometimes (*T. patula*) striped with red; the akenes are flattish, slender, and crowned with a few chaffy or awned scales.

Composition.—Calendula was analyzed by Geiger (1818), who, besides the usual constituents of herbs, found in it an amorphous bitter principle and *calendulin*, which is yellowish, tasteless, insoluble in ether, soluble in alcohol, and swelling with water into a transparent jelly.

Pharmaceutical Uses.—Tinct. calendula, *U. S.*, is prepared from the powdered herb; the direction to use the calendula *fresh* must evidently be interpreted to mean that the carefully-dried flowering herb is to be kept not longer than for 1 year. The florets of marigold form an ingredient of some fumigating-powders, being added on account of their bright color. *Fluid extract of calendula* may be prepared according to the formula for *Extr. calumbæ fluidum*.

Medical Action and Uses.—The leaves and the unexpanded flowers were at one time supposed to possess stimulant and resolute virtues, and were used in congestions of the *liver*, *jaundice*, *menorrhœa*, *scrofula*, and even in *typhoid* febrile states. Both internally and externally marigold was employed in the treatment of *cancer*, and was thought to dispose cancerous ulcers to heal. A solution of the extract and a decoction of the herb were employed for this purpose. A saturated tincture of the flowers is said to promote the cure of *contusions*, *wounds*, and simple *ulcers*. A tincture of calendula has (1881) been recommended in suppurative *otitis*, but as it was mixed with boracic acid, which was alone competent to the cure, the efficacy of the tincture may be doubted (*New York Med. Record*, xx. 729). The extract is alleged to have been very efficient in allaying chronic *vomiting*, as well as for the purposes above enumerated. It was given in doses of 2 grains (Gm. 0.10) several times a day.

CALLITRICHE.—WATER-STARWORT.

Callitriche verna, *Linne*.

Nat. Ord.—Callitrichaceæ.

Description.—The plant is a native of Europe, and of North America from Pennsylvania and New Jersey northward. It grows in stagnant waters and sluggish rivulets, has a stem 1 or 2 feet (.3 to .6 M.) long, radiating at the nodes, and nearly sessile, obovate, entire, and three-nerved floating leaves, which are crowded in a tuft and about $\frac{1}{2}$ inch (8 Mm.) long; the submerged leaves are longer and linear, the flowers monœcious and inconspicuous.

A closely-allied species, *Call. heterophylla*, *Pursh*, which is common in the Southern United States, has broadly spatulate and petiolate floating leaves, and is used for the same purposes as the Northern water-starwort.

Medical Action and Uses.—Water-starwort is esteemed in the Southern States as a diuretic in *dropsy*, and is administered in the form of a tincture or in spirits saturated with the plant. In decoction it is given to horses to promote diuresis.

CALUMBA, U. S.—CALUMBA.

Columbæ radix, Br.; *Radix colombo*, P. G.; *Radix columbo*.—Colombo, Columbo, E.; Colombo, Fr.; Kolombowurzel, G.

The root of *Jateorrhiza Calumba*, *Miers*, s. *Cocculus palmatus*, *Wallich*. *Bot. Mag.*, 2970, 2971; Bentley and Trimen, *Med. Plants*, 13.

Nat. Ord.—Menispermaceæ.

Origin.—Besides the plant named above, *Jateorrhiza palmata*, *Miers*, s. *Cocculus pal-*

matus, *De Candolle*, has been named as the source of the drug. The distinctive characters, supposed to depend upon the shape of the basal lobes of the leaves and the presence or absence of hairs in the male inflorescence, were proven by Hanbury to be unimportant and to exist on the same stem; hence he suppressed the name of a supposed species, retaining that of *J. palmata*. Bentley agrees with these views, but retains the name of *J. Calumba*. The name is derived from *kalumb*, the African name of the root.

The plant is indigenous to the forests of Mozambique, in the southern portion of Eastern Africa, quite abundant along the lower Zambesi River, and cultivated in some African and East Indian islands. It is a hairy perennial climber, which reaches the summits of lofty trees, has large nearly orbicular, cordate, and palmately-lobed leaves, and dioecious flowers. It grows from a short, thick, and irregular rhizome, and this gives off numerous fusiform roots, which are the portion collected during the dry season, cut into transverse slices, and dried in the shade.

Description.—Columbo-root exists in commerce in nearly circular disks, having a diameter of 1 to 2½ inches (25 to 63 Mm.), and a thickness of about ¼ to ½ inch (6 to 12 Mm.). From the considerable shrinking of the parenchyma the central portion is quite depressed, but the medullium shows two or three circles of projecting and radiating vascular bundles, and upon a fresh section the dark-colored cambium line becomes plainly discernible, together with the numerous radiating dark-colored and narrow bast-wedges. The fresh section is of a light or grayish-yellow color, more yellowish-brown in the outer bark, which externally shows a gray-brown cork. The root breaks very readily in all directions with a short and mealy fracture; its odor is slight, more prominent and characteristic on powdering or moistening; the taste is slightly aromatic, persistently bitter, and at the same time mucilaginous. As imported it is often more or less worm-eaten.

FIG. 45.

Calumba: transverse section, natural size.

Columbo-root enters commerce directly from Zanzibar or through Bombay and other Indian ports. 38,115 pounds were received in the United States in 1882; during the preceding year only 8336 pounds.

Constituents.—Columbo-root has been analyzed by Planché, Wittstock, Buchner, Lebourdais, and Boedeker. *Columbin* was obtained by Wittstock (1830) by evaporating the ethereal tincture of the root. Boedeker (1849) prefers to obtain it by shaking the turbid aqueous solution of the alcoholic extract with ether. It forms colorless, inodorous, and very bitter prisms and needles, and is soluble in alkalies and hot alcohol, and in acetic acid, less so in cold alcohol and ether, and nearly insoluble in water. Boedeker found the yellow color of the cell-walls due to *berberine*, which exists probably in combination with the straw-yellow bitter *columbic acid*; the latter is almost insoluble in cold water, sparingly soluble in cold ether, freely in alkalies and alcohol; the last two principles are probably formed from the first. *Columbin* is $C_{42}H_{41}O_{14}$; the addition of ammonia, NH_3 , may result in the formation of berberine, $C_{20}H_{17}NO_4$, columbic acid, $C_{22}H_{23}O_7$, and $3H_2O$. Buchner (1831) found in columbo-root also 35 per cent. of starch, 17 of pectin, 4.7 of gum, 5 of yellow resin, and a little wax. The root yields about 6 per cent. of ash.

Substitutions.—The roots of *bryonia* and of *Frasera Walteri*, which have been occasionally sold as columbo, have scarcely any resemblance to it, and are readily dis-

FIG. 46.

Calumba: trans. section through the outer portion; mag. 25 diam.

tinguished by their color and by the absence of the dark cambium zone and radiating lines.

Off. Prep.—*Extractum calumbæ, Br.*; *Extr. calumbæ fluid., U. S.*; *Infus. calumbæ, Mistura ferri aromatica, Br.*; *Tinct. calumbæ, U. S., Br.*

Medical Action and Uses.—Columbo is a pure stimulant stomachic tonic, increasing the appetite and improving the digestion. It does not constipate. In India it has long been used in the treatment of *diarrhœa*, *cholera morbus*, and *dysentery*, and in Europe it has been found an efficient remedy for the *vomiting* and *purging* incident to teething, for atonic *dyspepsia*, the vomiting of pregnancy, etc. Its special mode of action appears to depend chiefly upon its constituent berberine (see BERBERIS), although the associated columbin, which is intensely bitter, probably enhances the tonic power of the medicine. In order to preserve the infusion it may be prepared as follows: Take 1 ounce of powdered columbo, $\frac{1}{2}$ ounce of powdered orange-peel, 2 ounces of brandy, and 14 ounces of water. Macerate for 12 hours and filter. Or it may be prepared more quickly by displacement. If a laxative operation is desired, rhubarb may be added to the materials. The dose of columbo in powder is from 10 to 30 grains (Gm. 0.60–2.00). In this form it may be associated with carbonate of iron and a little ginger or orange-peel. The simple infusion, which is no longer officinal, is made with half a troyounce of columbo to a pint of water. *Dose*, 1 or 2 fluidounces (Gm. 32–64).

CALX, U. S., Br.—LIME.

Calcaria usta, P. G.; *Calcii oxidum, Calcaria, Calc viva, Calc usta, Oxidum calcicum, Burned lime, E.*; *Chaux, Chaux vive, Fr.*; *Kalk, Aetzkalk, Gebrannter Kalk, G.*
Formula CaO . Molecular weight 56.

Lime recently prepared by calcination and preserved in well-closed vessels in a dry place.

Preparation.—Lime is an alkaline earth which is obtained by calcining native carbonate of calcium, such as chalk, limestone, or marble, by which carbonic acid gas is given off, oxide of calcium remaining behind; CaCO_3 is decomposed into $\text{CO}_2 + \text{CaO}$. Prepared on the large scale from native carbonates, it contains also the impurities naturally existing therein, such as magnesia, ferric oxide, alkaline salts, silica, and clay. If the latter is present in sufficient quantity, it will slake feebly or not at all, and is then called *poor* or *over-burnt*. To obtain pure lime, pure calcium carbonate should be employed, and if the calcining has been done in a crucible the resulting mass should be moistened with water and again calcined to expel the carbonic acid gas completely. The same effect is produced on the large scale by constructing the lime-kiln in such a manner that the products of combustion pass over the limestone.

CALCIS HYDRAS, Br.; *Calcaria hydrica.*—Slaked lime, Calcium hydrate. *E.*; *Chaux éteinte, Chaux hydratée, Fr.*; *Kalkhydrat, Gelöschter Kalk, G.*—Formula CaH_2O_2 . Molecular weight 74.

The British Pharmacopœia gives the following directions for preparing it: Take of Lime 2 pounds; Distilled Water 1 pint (Imperial). Place the lime in a metal pot, pour the water upon it, and when the vapor ceases to be disengaged cover the pot with its lid and set it aside to cool. When the temperature has fallen to that of the atmosphere, put the slaked lime on an iron wire sieve and by gentle agitation cause the fine powder to pass through the sieve, rejecting what is left. Put the powder into a well-stopped bottle and keep it excluded as much as possible from the air. Slaked lime should be recently prepared.

Properties.—Burnt lime is in hard white or grayish-white, porous masses of the specific gravity 3.1 to 3.2. It is fusible with difficulty only before the oxyhydrogen blowpipe, giving off a splendid red light, but is not otherwise altered. It is inodorous, and has an alkaline reaction and a caustic, burning taste. When mixed with about one-half its weight of water it absorbs the latter, the air being at the same time expelled from the pores with a hissing noise; it then becomes heated and is converted into slaked lime, particles of this being mechanically carried up by the vapors; moistened with a small quantity of water, lime becomes luminous in the dark. At 15°C . (59°F .) it requires about 750 parts of water for solution, but at 100°C . (212°F .) over 1300 parts are necessary; hence a solution of lime saturated in the cold becomes turbid on being heated. Exposed to the air, it absorbs water and carbonic acid and is converted into hydrate and carbonate of calcium.

Slaked lime forms a soft white powder of spec. grav. 2.08 and of a strong alkaline taste

and reaction. It does not part with its water at 100° C. (212° F.), and becomes completely anhydrous only at a dull red heat, without melting previously. On exposure to the air it is converted into calcium carbonate. When lime is slaked, or slaked lime is mixed with sufficient water to form a thin magma, the mixture is called *milk of lime*.

Tests.—Lime mixed with water to a thin milk should be dissolved by nitric acid with but little effervescence (limit of carbonate), and without leaving more than a slight residue of insoluble matter. Distilled water agitated with slaked lime should give the reactions mentioned under *LIQUOR CALCIS*.—*U. S.*

Salts.—Slaked lime decomposes most of the alkaline and metallic salts by combining with their acids and forming *calcium salts*, which are colorless unless the acid be colored, have a neutral reaction upon test-paper, and impart to the flame of the blowpipe a yellowish-red color. Lime salts soluble in water are not precipitated by ammonia, but yield white precipitates with carbonate, phosphate, and oxalate of ammonium, and with sulphuric acid, the latter precipitate being soluble in a large quantity of water, and the former ones in acetic acid, with the exception of the oxalate. Those salts which are insoluble in water are dissolved by dilute hydrochloric acid, and this solution is not disturbed (that of calcium oxalate excepted) when solution of sodium acetate is added in excess; but if to this liquid a solution of ammonium oxalate is added, all the calcium will be precipitated as calcium oxalate.

Pharmaceutical Uses.—On account of its affinity for water, lime is employed in preparing absolute alcohol and strong ether; its affinity for acids renders it useful in the preparation of alkalies (ammonia, potassa, soda), alkaloids (quinine, strychnine, etc.), and certain organic acids and allied compounds (santonin). It is employed in preparing precipitated sulphur, in the manufacture of chlorinated lime and potassium chlorate, and in many other chemical processes. *Liquor calcis, U. S., Br.*, is a solution of it in water, and *Potassa cum calce, U. S.*, contains it as one of its active constituents.

Physiological Action and Medical Uses.—Owing to its strong affinity for organic elements, unslaked lime causes the decomposition of organized matter, and thus favors the solution of the animal and vegetable constituents of soils. With albumen it forms a horny mass. In like manner it is employed to arrest putrefactive fermentation in cesspools, sewers, slaughter-houses, dissecting-rooms, etc. It is used by tanners to remove the hair and cuticle from hides. It has a less affinity for water than the alkalies, and is therefore a less energetic caustic, but in forming a hydrate it evolves a large amount of heat, so that when taken internally in large doses it inflames the mucous membrane of the throat, œsophagus, etc., and even causes ulceration and gangrene of these organs and of the stomach, and death. As a caustic, quicklime has been employed from time immemorial, and was usually mixed with sulphuret of arsenic in the treatment of indolent and unhealthy *ulcers* and for removing superfluous *hair* from the skin. Quicklime may also be used to destroy *navi* and to establish *issues*, for which purposes a fragment of freshly-prepared lime should be laid upon the skin protected by adhesive plaster with a proper opening in it, and moistened with a few drops of water. The heat produced is estimated at 350° F., and so rapidly destroys the organization of the skin that the lime ought to be removed before it is entirely exhausted in order to prevent too deep an eschar. Mixed with wood-ashes, it has been employed in the treatment of *favus*, and in an ointment containing 1 part of lime to 20 or 30 of lard for the cure of *psoriasis* and indolent *ulcers*.

CALX CHLORATA, *U. S., Br.*—CHLORINATED LIME.

Calx chlorinata, U. S. 1870; Calcaria chlorata, P. G.; Chloris calcicus, Chloruretum calcis, Calcii hypochloris.—*Chloride of lime, Hypochlorite of calcium, Bleaching-powder, E.; Chlorure de chaux, Poudre de Tennant ou de Knox, Fr.; Chlorkalk, Bleichkalk, G.*

A compound resulting from the action of chlorine upon hydrate of calcium, and containing at least 25 per cent. *U. S.* (30 per cent. *Br.*, 20 per cent. *P. G.*) of available chlorine. Chloride of lime should be preserved in well-closed vessels in a cool and dry place.

Preparation and Composition.—Chlorinated lime was first prepared on an extensive scale by C. Tennant and Knox of Glasgow in 1799, and is manufactured in essentially the same manner at the present time, the improvements introduced at various times consisting in perfecting the apparatus and the production of chlorine. Well-slaked lime, free from dampness, is rubbed through a sieve, and the powder thus obtained is spread upon shelves which are placed in several tiers in boxes or chambers, into which

dry chlorine gas is conducted from the top as long as it is absorbed, care being taken to regulate the current of gas in such a manner that the temperature within the chambers does not rise higher than 25°C . (77°F .), in order to avoid the formation of calcium chlorate. According to Lunge (1881), in the presence in the calcium hydrate of an excess of about 4 per cent. of moisture, and at a temperature of about 40°C . (104°F .), a product containing 43 per cent. of available chlorine may be obtained.

The oldest view concerning the composition of chlorinated lime admits of a direct combination and the formation of CaOCl_2 , and since the whole amount of slaked lime cannot be thus converted, a portion of it was supposed to form a double compound with it, having the composition $2(\text{CaOCl}_2 \cdot \text{H}_2\text{O}) + \text{CaH}_2\text{O}_2$. But it is now generally admitted that a decomposition takes place, the precise nature of which is, however, by no means fully established. It has been assumed that the reaction occurs between two molecules each of calcium hydrate and chlorine. $2\text{CaH}_2\text{O}_2 + 2\text{Cl}_2$ may form $\text{CaCl}_2 + \text{Ca}_2\text{ClO} + 2\text{H}_2\text{O}$; that is, calcium chloride, calcium hypochlorite, and water, which have been by some supposed to be merely mixed together; but since alcohol does not dissolve one-half of the chlorine as CaCl_2 , others have regarded them to be combined, forming $(\text{CaCl}_2 \cdot \text{Ca}_2\text{ClO} \cdot 2\text{H}_2\text{O})$. Schorlemmer (1873) adopted the view previously suggested by Odling, that chlorinated lime is calcium hypochlorite, in which ClO is replaced by Cl ; that its formula is therefore $\text{Ca}(\text{ClO})\text{Cl}$, and that with water this compound yields calcium hypochlorite and chloride. If either of the above be the true composition of chlorinated lime, it should contain about 49 per cent. of available chlorine, while in fact it contains much less. This deficiency has been ascribed to various causes, but mainly to the difficulty or impossibility of exactly forming calcium hydrate without excess or deficiency of water, both of which causes act injuriously; the formation of some calcium chlorate under certain circumstances likewise accounts for a part of the loss. Fresenius and F. Rose (1861) regarded dry chlorinated lime as a compound of calcium hypochlorite and oxychloride with $4\text{H}_2\text{O}$, formed according to the equation $4\text{CaH}_2\text{O}_2 + 2\text{Cl}_2 = \text{Ca}_2\text{ClO} \cdot \text{Ca}_3\text{O}_2 \cdot \text{Cl}_2 \cdot 4\text{H}_2\text{O}$, and that this compound is decomposed by water into hypochlorite, chloride, and hydroxide of calcium. C. Stahlschmidt (1876) expressed the view that chlorinated lime may be considered as a calcium hydrate in which 1 atom of hydrogen is replaced by Cl , and that its formation is explained by the equation $3\text{CaH}_2\text{O}_2 + 2\text{Cl}_2 = 2\text{CaHClO}_2 \cdot \text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, which requires an amount of active chlorine equal to nearly 39 per cent. of the product, which result may be attained in practice. In certain cases, however, nearly 43 per cent. of chlorine has been reached, and this is accounted for by the presence of some moisture, by which the above chlorohydrate of calcium, as it may be called, is decomposed into hypochlorite and hydrate of calcium, $\text{CaCl}_2\text{O}_2 + \text{CaH}_2\text{O}_2$, the latter of which, with more chlorine, yielding again chlorohydrate; but to complete the conversion into hypochlorite (and chloride) of calcium a much larger amount of water seems to be necessary than could be retained by dry chlorinated lime. That aqueous solutions of chlorinated lime contain calcium hypochlorite was proven by Kingzett, who obtained this salt from concentrated solutions of the former placed in a freezing mixture or evaporated in a vacuum over sulphuric acid. Schorlemmer, Lunge, and others have shown that with nitric or sulphuric acid carefully added, avoiding excess, a distillate containing hypochlorous acid is obtained; that carbonic acid liberates in the solution hypochlorous acid; and that, after exhausting chlorinated lime with little water, the subsequent solutions contain calcium and chlorine uniformly in the proportion required by the formula $\text{Ca}(\text{ClO})\text{Cl}$.

Properties.—Chlorinated lime is a white or whitish powder or in friable lumps, dry or but slightly damp, with a feeble odor of chlorine and a disagreeable bitter and saline taste. Under various circumstances it may undergo decomposition on keeping, either with the evolution of oxygen or by conversion into a mixture of chloride and chlorate of calcium. On exposure to the air it absorbs and combines with carbonic acid and becomes moist. It has an alkaline reaction, but finally bleaches test-paper. It is partly soluble in water and in alcohol, wholly soluble in dilute hydrochloric acid (not more than a trifling residue of insoluble matter should be left, *U. S.*), with the evolution of chlorine and the production of calcium chloride; $2\text{Ca}(\text{ClO})\text{Cl}$ or $\text{Ca}_2\text{ClO} \cdot \text{CaCl}_2 + 4\text{HCl}$ yields $2\text{Cl}_2 + 2\text{CaCl}_2 + 2\text{H}_2\text{O}$. If chlorinated lime contains a larger percentage of calcium chloride than is indicated by one of the above formulas, its chlorine will not be liberated, and is therefore not *available chlorine* for bleaching purposes. The same decomposition is effected by an excess of all acids except carbonic, which liberates hypochlorous acid. The solution in diluted acetic acid shows the presence of lime by yielding with ammonium oxalate a white precipitate soluble in hydrochloric acid. The aqueous solution, mixed with binoxide of man-

ganese, mercuric, ferric, and other oxides, evolves oxygen (Mitscherlich), and if ammonium sulphate be added nitrogen is given off (Calvert, 1870). The solution in the presence of carbonic or other acid rapidly destroys vegetable colors, and this property finds extensive application in the arts. Distilled with alcohol, wood-spirit, some volatile oils, etc., chlorinated lime generates chloroform, and when it is mixed with certain organic substances in the dry state a gradual decomposition and development of heat take place, and may result at last in an explosion. The spontaneous explosions of chlorinated lime which are on record may probably be referred to such a cause.

Tests.—The solution of chlorinated lime in diluted hydrochloric acid may be tested for impurities in the same manner as a solution of calcium carbonate. The most important determination, however, is that of the amount of available or active chlorine present, and depends upon its oxidizing power. The methods in use are oxidation of arsenious oxide or of ferrous sulphate or of sodium hyposulphite, in the last case preceded by the liberation of iodine. The process adopted is as follows: “If 0.71 Gm. of chlorinated lime be mixed with a solution of 1.25 Gm. of iodide of potassium in 120 Ccm. of water, and 9 Gm. of hydrochloric acid be then added, the red-brown liquid should require for complete decoloration not less than 50 Ccm. of the volumetric solution of hyposulphite of sodium, corresponding to not less than 25 per cent. of chlorine.”—*U. S.* “10 grains, mixed with 30 grains of potassium iodide and dissolved in 4 fluidounces of water, produce, when acidulated with 2 fluidrachms of hydrochloric acid, a reddish solution which requires for the discharge of its color at least 850 grain-measures of the volumetric solution of hyposulphite of sodium, corresponding to not less than 30 per cent. of chlorine.”—*Br.* “If 0.5 Gm. of chlorinated lime be triturated with 100 Ccm. of water, and to this liquid be added 2 Gm. of potassium iodide, 20 drops of hydrochloric acid, and a little starch solution, the mixture should require for decoloration at least 28.5 Ccm. of decinormal solution of sodium hyposulphite, corresponding to not less than 20 (20.18) per cent. of chlorine.”—*P. G.* In the first part of these processes iodine is liberated from the potassium salt, thus causing the red color of the solution or a blue color in the presence of starch; the addition of the hyposulphite causes the formation of tetrathionate and iodide of sodium, the red or blue color disappearing as soon as all the free iodine has been converted into the latter salt. By a slight modification the test may be used to ascertain the true percentage of available chlorine.

Pharmaceutical Uses and Preparations.—Chlorinated lime is largely employed in the arts for bleaching purposes; it is used in preparing chloroform and *Liquor sodæ chlorinatæ*, *U. S.*; as *Vapor chlori*, *Br.*, it is used in the moist condition; and *Liquor calcis chloratæ*, *Br.*, is a solution of it in water.

FUMIGATIO CHLORI, *P. G.* 1872. For *stronger* fumigation use a mixture of table-salt and black oxide of manganese, each 1 part, and sulphuric acid 2 parts, previously diluted with 1 part of water. The *milder* fumigation is made of chlorinated lime mixed with water to a soft mass, vinegar being afterward added.

Physiological Action and Medical Uses.—The action of chlorinated lime resembles that of chlorine, with a superadded causticity derived from the lime in its composition. In moderate doses it appears sometimes to act as an irritant of the stomach and bowels, and if the quantity taken be large it produces heat in these organs, nausea, vomiting, and diarrhoea. If used in a mouth-wash it removes acid, bitter, or metallic tastes. Externally, it is an active irritant, and is sometimes moderately caustic. It dries suppurating surfaces and prevents gangrenous ulceration.

In solution of the strength of 20 or more grains (Gm. 1.50) to the ounce of water it has been regarded as a useful stimulant in purulent *ophthalmia*. This solution on lint is efficacious in *frost-bite* and also as an injection in *gonorrhœa*. In various forms of *ulceration of the mouth*, scorbutic, gangrenous, or arising merely from debility, chlorinated lime promotes cicatrization, and is useful for this affection in scarlatina. Indolent and specific ulcers of other parts, and *burns*, are favorably modified by its use. It may be included among the means of curing *itch* when applied on cloths in a solution containing from $\frac{1}{16}$ to $\frac{1}{4}$ part of chlorinated lime. But care must be taken lest it irritate the skin unduly.

In *typhus fever* it is thought to moisten and cleanse the tongue, allay delirium, and revive the functions of the skin. It tends to reduce excessive mucous secretions, and has been used with marked advantage in the treatment of *phthisis* and *chronic bronchitis* with profuse purulent expectoration. When this is fetid the action of the medicine is peculiarly efficient; and it may be prescribed in atomized inhalations as well as by the stomach. It has been used with success in the treatment of *serofulous glands*, both inter-

nally and in an ointment. Even in some cases of enlarged mesenteric glands its action has appeared to be salutary.

As a *disinfectant* chlorinated lime has been employed under a great variety of circumstances to suspend the decomposition of organic matter and neutralize the resulting foul effluvia. Besides being used for this purpose in privies, close-stools, dissecting-rooms, sewers, etc., it has proved to be very efficacious in correcting the *foul odors* connected with putrefaction in the living body, as in cases of *retained placenta* or uterine clots, *cancer of the uterus* and of other parts, *ozæna*, *mercurial salivation*, *foul breath* due to the decomposition of glandular secretions in the fauces, the fetor exhaled by the *armpits*, *feet*, etc. A false analogy led to its use for preventing contagion by the sick and by infected fomites, but there is no reason to believe that its influence exceeded that of the various measures of purification which were associated with it. Chlorinated lime decomposes hydrosulphuric acid, hydrosulphuret of ammonia, sulphuret of potassium, and hydrocyanic acid, and may therefore be used as a chemical *antidote* to these poisons. Persons *poisoned* by privy and by sewer gases have been restored by holding a cloth wet with a solution of this substance before the nostrils. A similar expedient has been used to protect persons in an atmosphere saturated with *sulphuretted hydrogen*.

The *dose* of chlorinated lime is from 1 to 5 grains (Gm. 0.06–0.30) in solution. From 10 to 60 grains (Gm. 0.50–4.00), dissolved in from 4 to 8 ounces of water and filtered, may be given in 24 hours. As a mouth-wash 1 part dissolved in 100 of water may be used. For external use the most energetic form of the preparation is that of a semi-fluid paste; the feeblest, to be at all useful, may contain 1 drachm (Gm. 4) of chlorinated lime in 8 ounces of water. An ointment for dry atonic ulcers may be made with equal parts of this preparation and lard; for enlarged glands, etc. the proportion of 1 drachm (Gm. 4) to an ounce of lard is sufficient.

CALX SULPHURATA, U. S.—SULPHURATED LIME.

Calcaria sulfurata, *Hepar sulphuris calcareum*, *Hepar calcis*.—*Sulfure de chaux*, Fr.; *Kalkschwefelleber*, G.

A mixture consisting chiefly of sulphide and sulphate of calcium (CaS and CaSO_4).

This preparation has been erroneously called *calci sulphidum*, s. *calcium sulfuratum*, and is usually dispensed when sulphide of calcium is prescribed.

Preparation.—Lime, in very fine powder, 100 parts; Precipitated Sulphur 90 parts. Mix the lime and sulphur intimately, pack the mixture with gentle pressure in a crucible so as to nearly fill it, and, having luted down the cover, expose the crucible for 1 hour to a low red heat by means of a charcoal fire so arranged that the upper part of the crucible shall be heated first. Then remove the crucible, allow it to cool, rub its contents to powder, and at once transfer them to small glass-stoppered vials.—*U. S.*

This is one of the formulas which have long been in use for the preparation of sulphurated lime, and in which the proportion of sulphur varied from 1 to 3 parts for 2 parts of lime. The proportions adopted by the Pharmacopœia are those of Hager, who gives the formula $3\text{CaS} + (\text{CaSO}_4)$ for the product. But to obtain such a mixture the sulphur is used largely in excess, for the reaction is assumed to take place as follows: $4\text{CaO} + 2\text{S}_2 = 3\text{CaS} + \text{CaSO}_4$, or between 224 parts of lime and 128 parts of sulphur, or 100 of lime and little more than 57 of sulphur, so that more than one-third of the sulphur used is in excess, and is either present simply as an admixture, or, more likely, different salts are mixed with calcium sulphides, for a polysulphuret is not attainable by fusion.

Properties.—Sulphurated lime is “a grayish-white or yellowish-white powder, gradually altered by exposure to air, exhaling a faint odor of hydrosulphuric acid, having an offensive alkaline taste and an alkaline reaction, very slightly soluble in water and insoluble in alcohol. On dissolving sulphurated lime with the aid of acetic acid, hydrosulphuric acid is abundantly given off and a white precipitate (sulphate of calcium) is thrown down. The filtrate yields, with test solution of oxalate of ammonium, a white precipitate soluble in hydrochloric, but insoluble in acetic acid.”—*U. S.*

A similar compound, discovered by Canton (1768), is phosphorescent in the dark after previous exposure to the sunlight; it was formerly known as Canton’s phosphorus, and was prepared by fusing together 2 parts of burned oyster-shell with 1 part of sulphur.

Tests.—“If 1 Gm. of sulphurated lime be gradually added to a boiling solution of 1.25 Gm. of sulphate of copper in 50 Ccm. of water, the mixture digested on a water-bath for 15 minutes and filtered when cold, no color should be imparted to the filtrate by 1 drop of test solution of ferrieyanide of potassium (presence of at least 36 per cent. of

real sulphide of calcium).”—*U. S.* This test requires the mixture to have the composition $\text{CaS} + \text{CaSO}_4$, the combining weight being 208.

Allied Compounds.—*CALCI SULPHIDUM*, *S. SULPHURETUM*, *S. SULFURATUM*.—Calcium sulphide, *E.*; Sulfure de calcium, *Fr.*; Schwefelcalcium, *G.* Formula CaS . Mol. weight 72.—Nearly pure calcium sulphide is obtained by intimately mixing 12 parts of powdered gypsum with 3 or 4 parts of lampblack or powdered charcoal, and heating the mixture in a covered crucible as long as gas is given off. The charcoal, combining with the oxygen of the calcium sulphate, escapes as carbonic oxide or carbonic acid, and leaves calcium sulphide, CaS , having a grayish, yellowish, or reddish color from impurities naturally present. It is inodorous, has an alkaline and a sulphurous taste, dissolves completely in 500 parts of water, and is gradually decomposed by water into hydrate and sulphhydrate of calcium.

CALCI OXSULPHURETUM, known in France as *sulfure de calcium* or *foie de soufre calcuire*. Mix sulphur 100 parts; slaked lime 300 parts; water 500 parts; boil, stirring frequently, until a portion when dropped on a cold slab will solidify; then pour out on a marble slab, and when cold keep the mass in well-stopped bottles.—*F. Cod.* It has a gray or greenish-gray color, and is a variable mixture of oxysulphuret and hyposulphite or sulphate of calcium.

A solution known in France as *sulfure de chaux liquide* is made by boiling for an hour 2 parts of lime previously slaked, 5 of sublimed sulphur, and 20 of water, water being added to preserve the original amount; the filtrate has the density 1.16.

A soft mass, containing *sulphhydrate of calcium*, CaH_2S_2 , and used as a depilatory, is prepared from 2 parts of slaked lime and 3 of water by passing into the mixture hydrosulphuric acid as long as it is absorbed. The mass, known as *Martin's depilatory*, has a strong sulphurous odor, and on standing separates into two portions, which are to be mixed when used; if properly prepared, an application for 8 or 10 minutes is sufficient for removing the hair.

PHOSPHORESCENT POWDER OR PAINT. Calcined oyster-shells or cuttlefish-bone 100 parts; caustic lime 100 parts; calcined sodium chloride 25 parts; mix and thoroughly incorporate from 20 to 25 per cent. (about 55 parts) of sulphur and from 3 to 7 per cent. (about 8 to 18 parts) of sulphide of calcium, barium, strontium, or magnesium; the luminosity may be increased by adding incinerated marine algae. The powder is rendered adhesive by means of varnish, collodion, etc. After exposure to the sunlight it will be luminous in the dark.

Medical Action and Uses.—Sulphurated lime acts as irritant and corrosive, and is seldom, if ever, used internally. It is decomposed in the stomach, liberating sulphuretted hydrogen gas. The dose of it internally is variously stated to be from $\frac{1}{10}$ to $\frac{1}{2}$ grain (Gm. 0.006–0.003) and from 3 to 6 grains (Gm. 0.20–0.40). Externally, it is sometimes employed, in baths containing from 1 to 4 ounces (Gm. 32–128) of the salt, in the treatment of *itch* and certain obstinate scaly diseases of the skin. (See *SULPHUR*.) It has also been used in an ointment (1 to 10 parts in 15 parts of lard) for similar purposes, and as an ingredient of depilatory preparations.

Calcium sulphide has been used, like potassium sulphide, in local and general baths for chronic diseases of the skin, chronic rheumatism, etc., and internally for chronic bronchitis, etc. It was given internally in doses of one-tenth of a grain, gradually increased to a grain (Gm. 0.004–0.060), in the treatment of *acne*, and with alleged success. But as milk of sulphur and other topical applications, as well as other internal treatment, were employed at the same time, the share of the sulphide in the result may have been, and probably was, very small.

In 1869, Dr. Ringer claimed for the sulphides generally, but especially for this preparation, the power of arresting suppuration (*Therapeutics*, p. 48), directing 1 grain of calcium sulphide to be dissolved in half a pint of water, and a teaspoonful of the solution to be taken every hour. Thus, to one-sixty-fourth of a grain of this compound, so administered, was ascribed the cure of scrofulous and tuberculous abscesses. After years of oblivion this method was revived by Dr. F. N. Otis (*New York Med. Jour.*, May, 1880), who claimed for it the power of arresting the suppuration of *boabs*, *furuncles*, and other abscesses; and a case was published in which the cure was attributed to it of a gastro-pulmonary fistula (*Phila. Med. Times*, xi. 73). Ultimately, a much more moderate estimate of the virtues of this preparation was furnished in a report to the Therapeutical Society of New York. It concluded “that in many cases of suppurative affections, ranging from the small pustules of acne to extensive suppurating surfaces, an appreciable, and often a very marked, benefit is derived from the use of calcium sulphide. . . . At the same time, its action is not uniform, and in many apparently favorable cases it will fail entirely. It is somewhat prone to irritate the stomach.” One-tenth of a grain every 2 hours, it is stated, is the full dose, although some patients will bear a grain three or four times a day. “It will occasionally produce headache and more or less eructation of sulphuretted hydrogen” (*Amer. Jour. Med. Sci.*, July, 1882, p. 268). The almost total silence of recent therapeutical works regarding this preparation seems to prove that the statements above made have not appeared convincing to the medical profession.

CAMBOGIA, U. S., Br.—GAMBOGE.

Gambogia. U. S. 1870; *Gutti*, P. G.; *Gummi-resina* (*Gummi*) *guttæ*, s. *gutti*, *Gutta gamba*, *Cambodia*.—*Gutte*, *Gomme-gutte*, Fr.; *Gummigutt*, *Gutti*, G.

A gum-resin obtained from *Garcinia Hanburii*, *Hooker filius*. Bentley and Trimen, *Med. Plants*, 33.

Nat. Ord.—Guttiferæ (Clusiaceæ).

Origin.—A medium-sized tree with glossy laurel-like leaves and small yellow dioecious flowers, the pistillate ones being on short pedicles. It was formerly regarded merely as a variety (pedicellata) of *Garc. Morella*. *Desrousseaux* (s. *G. pictoria*, *Roxburgh*; *G. Gutta*, *Wight*; *G. cambogioides*, *Royle*; *Hebradendron cambogioides*, *Graham*), and is indigenous to Siam, Cambodia, and Cochin China. Flückiger and Hanbury observed that the yellow milk-juice is secreted in unbranched ducts, which are principally located in the middle bark, and to a less extent in the dotted vessels of the alburnum, in the pith, leaves, flowers, and fruit. Gamboge is obtained by incisions made into the bark, the latex being collected in the joint of a bamboo, occasionally also in other vessels, where it is allowed to harden.

Description.—Gamboge is in cylindrical, either solid or hollow, straight or bent, sticks, 6 to 8 inches (15 to 20 Cm.) long and 1 to 2 inches (25 to 50 Mm.) in diameter, called "pipes;" the surface is striated longitudinally from impressions of the bamboo, and occasionally contains some splinters of it. Gamboge breaks easily with a flattish conchoidal, smooth fracture, of a deep orange-red tint and of a waxy, somewhat resinous lustre; thin splinters are slightly translucent. It yields a bright-yellow powder, and on being triturated with water a uniform bright-yellow emulsion is readily obtained. This emulsion forms with ammonia-water a clear deep-red afterward brown solution, the liquid becoming colorless on the addition of acids, the yellow resin being precipitated. Gamboge is inodorous, but the dust is sternutatory, and it has a disagreeable acrid taste. Inferior qualities of pipe gamboge are of a brown or gray tint, harder, of a dull earthy or irregular fracture, and less inclined to produce a uniform emulsion.

Cake gamboge has been collected in flat vessels, and is met with in irregular lumps, which otherwise resemble pipe gamboge, but are more liable to be adulterated.

Constituents.—Aside from accidental impurities, like cellular tissue, gamboge contains about 4 per cent. of moisture, the remainder being resin, and 16 to 20 per cent. of gummy matter, which is not identical with gum-arabic. The resin is called *camboëic acid*, is soluble in alcohol, ether, and with a deep-red color in dilute alkalies, and from the latter solution is precipitated unaltered by acids; its solutions yield a yellow precipitate with lead acetate, and brown ones with iron and copper salts. By fusing it with caustic potassa, Hlasiwetz and Barth (1866) observed the disengagement of vapors having the odor of lemon and melissa, and found in the residue, besides acetic and volatile fatty acids, also *phloroglucin* and *pyrotartaric* and two other acids. Gamboge is free from starch, and if adulterated with it an emulsion made with hot water will turn green by solution of iodine, or it may be recognized in the residue left after treatment with alcohol and cold water.

Off. Prep.—*Pilulæ catharticæ comp.*, U. S.; *Cambogiæ comp.*, Br.

Physiological Action.—Experiments upon animals with gamboge do not render its operation clear. It produces few symptoms of local irritation, but little evidence of pain, fever, nervous motor derangement, or coma, and not uniformly either vomiting or purging. In man, applied to the raw skin, it acts as an irritant. Internally, in small doses, it appears to increase the glandular secretions, but in large doses causes colic and tenesmus. But there is no evidence of its increasing the secretion of bile. In doses of 3 or 4 grains (Gm. 0.20–0.25) it occasions liquid stools, with little or no colic. Rutherford's experiments led him to conclude that gamboge is not a cholagogue, although it violently irritates not only the duodenum, but the whole of the small intestine. He remarks that colchicum, which is equally irritant, is decidedly cholagogue, and infers, therefore, that duodenal irritation alone is not sufficient to increase the excretion of bile. The purgative virtue of gamboge appears to reside in its resinous element. When given in small and repeated doses it is said to cause diuresis. There is no evidence of its having ever produced fatal effects.

Medical Uses.—Gamboge is seldom employed unless associated with other purgatives. It is reputed to be well adapted for relieving such congested states of the *liver* as arise from malarial causes. In these cases it is usually associated with calomel. As a *hydragogue*, acting by the kidneys as well as the bowels, its merits appear to be well

established. For this purpose it should be given in small and repeated doses, such as a grain (Gm. 0.06) every hour, dissolved in sweetened water. It is often associated with jalap and with bitartrate of potassium. Its want of taste fits it for use by children. It is sometimes employed as a *vermifuge*, and is then usually prescribed with vermicide medicines.

Gamboge is administered in substance, in the average *dose* of from 1 to 5 grains (Gm. 0.06–0.30). It is most efficient when mixed with water and sugar. A convenient formula is the following: B. Gamboge gr. x; Carbonate of potassium 5j; Cinnamon-water f3ij. —Mix. S.—30 drops three times a day in water.

CAMPHORA, U. S., Br., P. G.—CAMPHOR.

Camphre, Fr.; *Kampfer*, *Campher*, G.

Formula $C_{10}H_{16}O$. Molecular weight 152.

A stearepten or concrete volatile oil obtained from the wood of *Cinnamomum Camphora*, *F. Nees et Ebermaier*, s. *Camphora officinarum*, *C. Baubin*, s. *Laurus Camphora*, *Linné*, and purified by sublimation. *Woodv., Med. Bot.*, plate 155; *Bentley and Trimen, Med. Plants*, 222.

Nat. Ord.—Lauraceæ.

Origin.—The camphor laurel is a handsome tree 25 to 30 feet (7.5 to 9 M.) high, with thin reddish or yellowish branches, and alternate evergreen, smooth, and shining leaves, which are glaucous beneath. The flowers are small, yellowish, in pedunculate axillary cymes, and produce oblong-globular dark-purple berries about $\frac{1}{4}$ inch (8 Mm.) long and containing a single seed. It is indigenous to Eastern and South-eastern Asia from Cochin China north through China, and in Japan and Formosa. It grows very readily in tropical and subtropical countries, and is cultivated in Italy as an ornamental tree. All parts of the tree have a camphoraceous odor and taste, but the camphor is obtained from the root, trunk, and branches by chipping the wood, and either boiling it with water in an iron vessel which is covered with a rude earthen or wooden head lined on the inside with straw, in which the camphor condenses, or as in Formosa, where the chips are merely exposed to the vapor of water, which is boiled in a wooden trough, lined on the outside with clay, earthen pots, ten in number, serving as the heads of the rude still. The camphor is scraped out from time to time, placed in suitable vats to drain off much of the adhering oil, and then packed. Camphor appears to have been used as a medicine in Europe in the twelfth century. The kind first known was *Dryobalanops camphor*, which is now seen only as a curiosity outside of Southern Asia.

Commerce.—*Japan* or *tub camphor*, formerly also called Dutch camphor, is imported in tubs containing about 125 pounds, covered by matting and surrounded by another tub. It is in white granular masses, usually with a reddish tint and dry to the touch. *Formosa* or *Chinese camphor*, generally imported in lead-lined chests, is occasionally as handsome in appearance as the preceding, but frequently is in smaller granules, darker, sometimes even blackish in color, or damp from adhering oil or moisture. Crude camphor dissolves completely in alcohol, with the exception of from 1 to 5 or 6 per cent. of foreign matters, sand, etc. In the fiscal year 1866–67, 432,075 pounds of crude and 30,526 pounds of refined camphor passed through the custom-houses of the United States. Since 1876 very little refined camphor has been imported, it varying between 208 pounds in 1877 and 11 pounds in 1882, while in the same period the importation of crude camphor fluctuated between 986,292 pounds in 1879 and 2,542,830 pounds in 1880.

Refining.—This was formerly done exclusively in Europe, but it has for some years been successfully carried on in the United States. It is stated that the apparatuses used in Europe are still the old-fashioned *bombaloes*, large somewhat depressed glass globes with a short neck and an aperture through which the watery vapors find egress; some charcoal or lime is introduced with the crude camphor into the vessels, which are placed in a sand-bath, and this is rapidly heated, first to expel the water, after which the sand is lowered and the heat gradually increased to between 200° and 205° C. (392° and 401° F.); after the camphor has sublimed and condensed at the top the vessels must be broken in order to recover the purified camphor. Similar subliming-vessels are in use in the United States, but they are so arranged that they can be taken apart and used over again, and provision has even been made by a firm in Philadelphia to recover the volatile oil contained in the camphor. The operation requires a careful regulation of the heat for subliming and judicious provision for cooling the top, so as to obtain the camphor in solid crystalline cakes. Another Philadelphia firm sublimes the crude camphor slowly from retorts and condenses the

vapors in a large chamber, whereby the camphor is obtained in a fine crystalline powder, which is afterward, by hydraulic pressure, formed into solid cakes, thus lessening the surface of exposure and the rapidity of evaporation.

Properties.—Refined camphor forms orbicular slightly convex cakes, with a circular hole in the centre, corresponding to the aperture of the subliming-vessel. It is white, translucent, crystalline in texture, fissured in the interior, tough, and not pulverizable, except after moistening it with alcohol, ether, chloroform, or a volatile oil. It evaporates slowly at the ordinary temperature, and condenses in partly-filled bottles in the form of glossy hexagonal plates or prisms. Various contrivances have been suggested to keep camphor in the powdered condition, such as precipitation by water in the presence of magnesia, trituration with a fixed oil, glycerin, or sugar; but the most satisfactory method appears to be that proposed by J. C. Lowd (1871), of condensing the hot camphor vapors in a large chamber. When kept in a cool place the powder thus obtained, which is sometimes called *flowers of camphor*, may be preserved for some years, and even if it should cake together may readily be reduced to the pulverulent condition.

Camphor fuses at 175° C. (347° F.), boils at 205° C. (401° F.), sublimes without leaving any residue, and when ignited burns with a luminous sooty flame; its specific gravity at 15° C. (59° F.) is 0.990 to 0.995. It is sparingly soluble in water (see AQUA CAMPHORÆ), dissolves at 15° C. (59° F.) in 0.7 parts of alcohol, and is freely soluble in ethers, chloroform, glacial acetic acid, wood-spirit, acetone, carbon disulphide, benzol, benzin, and volatile and fixed oils; its solutions in alcohol and ether increase the solubility of corrosive sublimate, and the presence of this salt renders camphor more soluble in these liquids. (See HYDRARG. CHLOR. CORROS.) Camphor dissolves by trituration in 10 parts of milk, and the solution may be diluted with water without causing precipitation. When rubbed together with powdered chloral or resins the mixtures gradually become soft or liquid, and in the fused state resins dissolve a considerable proportion of camphor. It has a peculiar penetrating odor and an aromatic somewhat cooling taste. The odor of camphor is destroyed by Tolu balsam, asafetida, and similar umbelliferous resins. Thrown upon water, camphor shows a peculiar rotating motion, which is probably caused by its rather rapid evaporation and slow solubility. It turns polarized light to the right.

Its composition is represented by the formula $C_{10}H_{16}O$. When distilled with chloride of zinc or phosphoric anhydride it is gradually converted into cymol, $C_{10}H_{14}$, and by oxidation with nitric acid into *camphoric acid*, $C_{10}H_{16}O_4$, and finally into *camphoronic acid*, $C_9H_{12}O_5$. Schwanert's *camphresinic acid* (1863) is a mixture of these two. By the action of hypochlorous acid on camphor Wheeler (1868) obtained several chlorine substitution-products, and by acting upon these with alcoholic solution of potassa *oxycamphor*, $C_{10}H_{16}O_2$, is formed, which crystallizes in needles, has the odor and taste of camphor, and sublimes without change, but melts at 137° C. (278.5° F.). Camphor combines and forms also substitution-compounds with iodine and bromine.

Other Camphors and Camphor Oils.—The crystallizing stearoptens of volatile oils are sometimes designated as camphors.

OLEUM CAMPHORÆ, U. S. 1870.—Oil of camphor, Camphor oil of Formosa, *E.*; Huile volatile de camphre, *Fr.*; Flüchtiges Kampheröl, *G.*—The oil is obtained in the preparation of crude camphor, and a portion also in refining this product. It is a dark wine-yellow or yellowish-brown liquid, having a camphor-like odor and taste and the specific gravity .940. At a low temperature it deposits a considerable quantity of camphor in the form of crystals, and at about 180° C. (356° F.) it begins to boil. It turns the plane of polarized light to the right. By careful fractional distillation a considerable portion of camphor is left in the retort, but cannot be completely removed by this means. The liquid distillate has, according to Martius, the odor of camphor and cajuput, and, according to Mulder, is a solution of laurel camphor, $C_{10}H_{16}O$, in a hydrocarbon of the composition $C_{10}H_{16}$; the latter, according to Lallemand (1859), resembles oil of lemon in its chemical behavior.

SUMATRA, s. BORNEO CAMPHOR, or BARUS CAMPHOR, is found in fissures of the wood of *Dryobalanops Camphora*, *Colebrook* (*D. aromatica*, *Gaertner*). Nat. Ord. Dipterocarpaceæ. Its odor is somewhat different from that of ordinary camphor; its crystals are slightly heavier than water, and but sparingly volatilized at ordinary temperatures. It is *borneol* or *camphyl alcohol*, $C_{10}H_{18}O$, and by treatment with nitric acid it is converted into ordinary camphor. The stately tree yielding this drug is indigenous to Sumatra and Borneo, and requires cutting down to obtain the camphor, which in the East is sold at a high price, and therefore never enters commerce at large. This camphor is dextrogyre.

CAMPHOR OIL OF BORNEO is obtained from the same tree by tapping or felling it. It is a rather viscid brown-yellow or reddish oil, which is a solution of resin and a little borneol in a hydrocarbon, $C_{10}H_{16}$; the latter has a terebinthinate odor, and is identical with the hydrocarbon of oil of valerian; hence the names *borneene* and *valerene*. Lallemand (1859) could not obtain borneol,

but isolated two terpenes boiling respectively at 180° and 255° C. (356° and 491° F.). The crude oil is dextrogyre, begins to boil at about 175° C. (347° F.), and deposits little or no camphor when placed in a freezing mixture. It is rarely, if ever, met with in commerce.

NGAI CAMPHOR is obtained in Burmah and China by the distillation of *Blumea balsamifera*, *De Candolle*: Nat. Ord. Compositæ—a tall weed of South-eastern Asia, and commands there a higher price than ordinary camphor. It has the composition of the Borneo camphor, $C_{10}H_{18}O$, but turns polarized light to the left, and yields with nitric acid a camphor having the composition of ordinary camphor, but levogyre in optical behavior. It was examined in 1874 by Hanbury, Plowman, and Flückiger.

Pharmaceutical Uses and Preparations.—Camphor is used in preparing monobromated camphor, and is a constituent of the following official preparations: *Aqua camphoræ*, *U. S.*, *Br.*; *Linim. aconiti*, *Linim. belladonnæ*, *Br.*; *Linim. camphoræ*, *U. S.*, *Br.*; *Linim. camphoræ comp.*, *Linim. chloroformi*, *Linim. hydrargyri*, *Linim. iodi*, *Linim. opii*, *Br.*; *Linim. saponis*, *Linim. sinapis comp.*, *U. S.*, *Br.*; *Linim. terebinthinæ*, *Linim. terebinth. comp.*; *Br.*; *Mistura chloroformi*, *U. S.*; *Spiritus camphoræ*, *Tinct. opii camphorata* (*camph. comp.*), *U. S.*, *Br.*; *Ung. hydrarg. comp.*, *Ung. plumbi subacet.*, *Br.*

VINUM CAMPHORATUM, *P. G.*—Wine of camphor, *E.*; *Vin camphré*, *Fr.*; *Kampferwein*, *G.*—Dissolve camphor 1 part in alcohol 1 part, and add gradually and with agitation mucilage of acacia 3 parts and white wine 45 parts. It is a whitish, turbid liquid, which requires to be well shaken when dispensed.—*P. G.*

CAMPHORA CARBOLISATA, s. **PHENOLATA**.—Camphorated phenol, *Phenol-camphor*, *E.*; *Camphre phenolé*, *Fr.*; *Phenolkampher*, *G.*—Camphor 2 parts; carbolic acid 1 part; allow to liquefy (*Buflini*, 1875). Camphor 100 parts, carbolic acid 36 parts, alcohol 4 parts; dissolve (*Hager*). A colorless or oily liquid having the odor of camphor, soluble in fixed oils, alcohol, and ether, nearly insoluble in water and glycerin.

CAMPHORA SALICYLATA.—Salicylated camphor, *E.*; *Camphre salicylé*, *Fr.*; *Salicylirter Kampfer*, *G.*—Camphor 84 parts, salicylic acid 65 parts; heat in a water-bath to 90° C. (194° F.) until liquefied (*Prota Giurleo*, 1881). A colorless oily liquid, solidifying to an opaque crystalline mass, becoming unctuous on being triturated; slightly soluble in water and glycerin, more soluble in fats and volatile oils, and crystallizing from hot benzol.

Physiological Action.—*On Vegetables and Animals*: Camphor at first stimulates, but ultimately kills, plants, causing them to fade and wither. It does not appear to prevent the germination of seeds. It destroys insects; in birds it produces an excited intoxication, followed by stupor and convulsions; in frogs it manifests, in small doses, a depressing influence upon reflex motility and a stimulant action upon the heart; but in large doses it paralyzes that organ. Given in full doses and by the mouth to dogs, it occasions general excitement, with signs of gastric distress, which are followed by tremor, lowering of temperature, convulsions, and death. It appears to increase the arterial blood-pressure. After death the stomach is found injected and the venous system and the heart are distended with dark blood.

On Man: The local action of camphor upon the living tissues is that of a stimulant and irritant. A piece of it held in the mouth irritates, and may even ulcerate, the lining membrane; the same effect is produced in the stomach. Internally, its action varies with the dose. In large doses it causes a burning pain at the pit of the stomach, diminished frequency and force of the pulse, followed by its intermission, by giddiness, dimness of vision, muscular debility, paleness and coolness of the skin, with a cyanotic hue in grave cases, spasms and rigidity of the muscles, and general convulsions. These phenomena, which show that camphor in large doses is a direct and powerful sedative, are followed by a reaction in which there is more or less excitement and fever. In no instance does camphor seem to have directly caused the death of a healthy person. An ounce of camphorated oil induced sleep at first, then violent delirium, vomiting, labored breathing, and a pulse of 104, but of good strength (*Lancet*, Jan. 1880). A drachm each of camphor and hydrate of chloral, taken together, caused speedy unconsciousness, coldness, and flaccidity of the limbs, a slow and feeble pulse, and a narcotism that did not cease for 4 days, followed by a mental confusion that continued for 9 or 10 days (*Simmons*). In smaller but still excessive doses it produces a peculiar intoxication, with delirium, in which great mental vivacity and muscular activity are displayed—a condition compared to that which is apt to be produced by champagne wine; but these effects are transient, and are followed by depression, pallor, coldness, profuse sweating, and dysuria. In medicinal doses (gr. ij to gr. xv = Gm. 0.12 to 1.0) camphor stimulates the nervous and vascular systems, and through them all the functions; the pulse becomes stronger and more frequent, the skin grows warmer and moister, and there is a

consciousness of more or less exhilaration. Such effects are of short duration, and are not succeeded by exhaustion or depression. Small doses appear to irritate the genital organs, but full medicinal doses allay morbid excitement in them. It appears, then, that camphor stimulates in small and depresses in large doses, and that its operation is very transient—almost as much so as that of alcohol, which in some other respects it resembles. According to physiological experimenters, the spinal cord is not influenced by camphor, for convulsions do not occur after the separation of the medulla oblongata from the medulla spinalis. Owing to the rapid disappearance of the smell of camphor from the urine and feces of animals poisoned by it, it is held that the drug is decomposed in the organism.

Medical Uses.—The ancients do not appear to have used camphor in febrile affections, but in the eighteenth century it acquired a reputation in the treatment of *typhoid conditions* which it has never lost. It was held to be less heating than ammonia, less stupefying than opium, and, along with the latter, to act as a powerful sudorific. It was considered—and is, in fact—an appropriate remedy for the condition which includes exhaustion, stupor, and nervous derangement, shown by muscular trembling and subsultus and low delirium, the phenomena belonging to the malignant or typhoid state in which the nervous system tends to collapse because the blood has become impure. In this condition stimulants sustain nervous power until the depuration and reorganization of the blood are accomplished; and camphor in small and repeated doses has the advantage, over some other appropriate remedies, of inducing no injurious secondary effects. The typhoid state, it should be remembered, may be an incident of inflammatory affections as well as of idiopathic fevers. A French army surgeon claims that in the treatment of an epidemic of typhoid fever marked by unusual ataxia he was very successful after he began the administration of enemata containing 8 grains of crystallized carbolic acid, 15 grains of camphor, 1 ounce of alcohol, and about 6 ounces of water (*Bull. de thérap.*, ciii. p. 465). The share of the carbolic acid in the alleged result may well be disregarded. In *spasmodic diseases* camphor has been largely employed in whooping cough, chorea, and even epilepsy, but its power in these affections is of very subordinate importance. In minor disorders of this class, such as nervous *headache*, nervous *palpitation*, *hiccup*, *spasmodic dysphagia*, etc., camphor in small and repeated doses shows the same power as other nervous stimulants. In small doses, or even as a topical application, it seems to afford marked relief in that distressing occipital headache which arises from severe and prolonged mental strain. In full sedative doses it has proved an antidote to *strychnia*. The Arabians and their followers in Europe were familiar with the power of camphor in large doses to repress *sexual excitement*, and they, as well as nearly all successful imitators of them, prescribed from 20 to 60 grains a day. The doses of 2 or 3 grains sometimes directed for this purpose are worse than useless. They are perhaps more efficient in certain cases of genital excitement produced by local irritation—by cantharides, for example. It is usual to incorporate powdered camphor with blistering plasters to prevent *strangury*, but the evidence of the efficiency of this expedient is not very strong. A poultice saturated with camphor and applied to the perineum will relieve this symptom, and also prevent *chordee*. In some cases of *mania* large doses of camphor have proved efficient, particularly in the puerperal form; it very probably would be more eligible than the excessive doses of opiates which are sometimes employed. It is stated that equal parts of chloral hydrate and camphor form a much more powerful sedative and soporific than a like dose of either substance alone (*Simmons, Amer. Jour. of Med. Sci.*, Jan. 1880, p. 89). Camphor has been employed to expel *lumbricoid worms*, and by enema to destroy *ascarides* of the rectum. It has been resorted to internally and locally with good effect in hospital *gangrene*. *Ulcers* that are slow to heal, owing to a depressed state of the system, are benefited by camphor in powder; the same may be said of specific ulcers of the genitals. Camphor dissolved in ether or chloroform, or even alcohol, and applied on cotton within the cavity of a carious tooth, mitigates *toothache* materially. This is one of the most ancient uses of the medicine. Snuffed into the nostrils, camphor, like other local irritants, will sometimes arrest a forming *coryza*. In an ointment or liniment it forms one of the best cures for *scabies*, and is said to prevent the maturation of *variolous* pustules.

Camphor may be administered in substance in the pilular form when the dose is small, but larger doses are best given in emulsion, which should be flavored with the extract or the syrup of liquorice. As a stimulant the *dose* is from 1 to 5 grains (Gm. 0.06–0.30), repeated every 3 or 4 hours in mild cases, but in low fevers it should be from 10 to 20 grains (Gm. 0.60–1.20), and repeated according to the indications. In maniacal nervous excitement not less than 20 grains (Gm. 1.30) should be given, and repeated as often as

may be required. In cases of *poisoning* by camphor, alcohol may be administered in small and repeated doses.

CARBOLIZED CAMPHOR is prepared as follows: Carbolic Acid 9 Gm.; Camphor 25 Gm.; Alcohol 1 Gm. Mix, and add Olive Oil 35 Gm. It has been applied with a brush to the false membranes of *diphtheria*, and is stated to have caused a rapid subsidence of the inflammatory swelling and a removal of the exudation (*Bull. de thérap.*, xciv. 18; xcvi. 529).

SALICYLATED CAMPHOR is a mixture of equal parts of salicylic acid and camphor, with the addition of a few drops of alcohol, which should be mixed with from 10 to 20 parts of vaseline. By the addition of paraffin this ointment can be made into suppositories. It is stated to exhibit remarkable healing powers when applied to phagedenic and atonic *ulcers*, especially those of a syphilitic nature (*Bull. de thérap.*, xcvi. 143).

WINE OF CAMPHOR is used for the same purposes as spirit of camphor.

CAMPHORA MONOBROMATA, U. S.—MONOBROMATED CAMPHOR.

Bromated camphor, E.; *Camphre monobromé*, Fr.; *Monobromkampher*, G.

Formula $C_{10}H_{15}BrO_2$. Molecular weight 230.8.

Preparation.—Laurent obtained (1840) bibromide of camphor, $C_{10}H_{16}OBr_2$, by uniting bromine with camphor, and stated that on distillation it afforded bromine, camphor, a little hydrobromic acid, and a bromated oil. Swarts (1861) heated camphor bibromide in sealed tubes and obtained monobromated camphor. W. H. Perkin (1865) subjected the oily bromide of Laurent to distillation, and found the distillate, collected above $265^{\circ} C.$ ($509^{\circ} F.$) after crystallization from alcohol, to be monobromated camphor. We have found (1872) the following process to give satisfactory results: Break 13 ounces of camphor into small pieces; put these into a quart retort, first filling the neck; raise the latter somewhat, and then introduce through the tubulure, by means of a funnel-tube, 4 ounces of bromine, washing the last down with 20 or 30 minims of alcohol. A brisk reaction will commence in about 15 or 20 minutes; after it has subsided and the retort has become cool introduce 8 to 9 ounces of bromine in four portions, waiting after each addition until the reaction has ceased. The addition of alcohol is not requisite, but facilitates the reaction, and the bromine may be added in larger quantities if provision be made for condensing the vaporized bromine and returning it to the retort. This is now slowly heated to about $132^{\circ} C.$ ($270^{\circ} F.$), allowed to cool, the contents dissolved in warm petroleum benzin, the solution allowed to crystallize, and the crystals purified by recrystallization from hot alcohol or petroleum benzin. On evaporating the mixed mother-liquors an oily mass is obtained, which, heated to $260^{\circ} C.$ ($500^{\circ} F.$), becomes black, and contains monobromated camphor, to be obtained by recrystallization as before. Gault (1874) heats at first in a water-bath, crystallizes from strong alcohol, and heats the oily mass contained in the mother-liquor to not over $220^{\circ} C.$ ($428^{\circ} F.$). A similar process is recommended by Dubois, who states that by confining the heat to $100^{\circ} C.$ no by-products of any consequence are formed. J. U. Lloyd (1875) recommends the camphor bibromide to be heated with water in a retort placed in a sand-bath, and the product to be crystallized from alcohol. T. C. Linthicum (1876) considers the reaction very unsatisfactory at $100^{\circ} C.$

In the above processes bibromide of camphor, $C_{10}H_{16}OBr_2$, is first formed, and this, on being heated, is decomposed into hydrobromic acid, HBr , and monobromated camphor, $C_{10}H_{15}BrO$, the latter representing a molecule of camphor in which 1 atom of hydrogen is replaced by 1 of bromine. During the operation one-half of the bromine used is given off as hydrobromic acid, and may be collected in water or combined with a base.

Properties.—Monobromated camphor crystallizes from alcohol in thin white or colorless prisms and needles, and from petroleum benzin in long flat prisms or glossy scales. It has a weak but persistent camphoraceous odor, a mild camphoraceous taste, and a neutral reaction. It is permanent in the air and not affected by direct sunlight. It is insoluble in water, slightly soluble in glycerin, freely soluble in alcohol, ether, chloroform, fixed oils, and in less than its own weight of hot petroleum benzin, from which solution the greater part crystallizes on cooling. It melts at $76^{\circ} C.$ ($168.8^{\circ} F.$), and evaporates slowly with the vapors of boiling water, condensing in fine white interlaced needles; at $274^{\circ} C.$ ($525^{\circ} F.$) it boils and volatilizes completely, with partial decomposition. It dissolves without decomposition in cold sulphuric acid, and is again precipitated by water. When boiled with nitrate of silver and nitric acid it is decomposed, and yields

81.2 per cent. of bromide of silver. Heated with zinc chloride to near 160° C. (320° F.), it yields a hydrocarbon, C_8H_{16} , and liquid thymol, $C_{10}H_{14}O$ (Schiff, 1880).

Pharmaceutical Uses.—If a liquid preparation is desired, monobromated camphor is conveniently given in the form of emulsion, after dissolving it in six or eight times its weight of expressed oil of almond or other bland oil. Monday (1877) proposed an *elixir of monobromated camphor* containing 1 per cent. by weight of the latter, by dissolving with the aid of a gentle heat 3 Gm. of it in a mixture composed of 120 Gm. of 90 per cent. alcohol, 80 Gm. of water, and 100 Gm. of glycerin.

Physiological Action.—From a number of experiments upon animals Bourneville drew the following conclusions: 1. Monobromated camphor diminishes the number of the heart-beats and contracts the blood-vessels of the ears and eyelids. 2. It renders the inspirations less frequent. 3. It lowers the temperature steadily, and in fatal cases until death; in those animals which recover the temperature rises to its original point, but more slowly than it fell. 4. It is unquestionably hypnotic, and seems to act chiefly upon the brain. 5. It does not appear to induce tolerance, and cats and guinea-pigs lose flesh rapidly while using it. But Trasbot reports that, experimenting upon dogs, he never observed in them either somnolence or the lowering of the pulse or temperature. On the contrary, in doses varying from 7 to 15 grains (Gm. 0.40–90) this preparation induced convulsions identical with those caused by strychnia. Again, Valenti y Vivo inferred from his experiments that it may be considered an antidote to strychnia, although it must be freely exhibited for this purpose. The experiments of Mr. Lawson upon man tend to confirm the conclusions of Bourneville in regard to its influence upon the pulse and temperature, both of which were depressed under the action of the compound, but in doses of 10 grains it did not show any soporific influence. In his subsequent trials of the medicine he found that its great liability to produce gastric irritation, and the excitability and wasting following thereon, formed a strong objection to its use.

Medical Uses.—Monobromated camphor has been used with alleged advantage in *epilepsy*, not only in the convulsive form of the disease, but in *epilepsia minor*, and in cases of epileptic delirium in females. But, according to Dr. Gowers, it in his hands produced no good results. It has appeared to arrest *convulsions* depending upon dentition. In several cases of inveterate *chorea* and of *paralysis agitans* it is reported to have mitigated the convulsive movements in a notable degree, and to have controlled the excitement of *hysteria* and also of *delirium tremens*. In *insomnia* connected with cerebral hyperæmia or with heart lesions it has proved beneficial, and *palpitation* of the heart due to either cause has been relieved by it. The same is true of its use in *headache* occasioned by over-stimulation of the brain by mental excitement. It has also palliated *nervous cough* and nocturnal *incontinence of urine*, relieved anal and vesical *tenesmus*, especially when this symptom depended upon nervous irritability and not upon substantial disease of the affected organs, and it has also subdued *præpism*. It will be observed that all of these affections are such as are apt to be benefited by the alkaline bromides; and it is more than probable that a solution of one of them in camphor-water, if not in simple watery solution, would answer the same purpose. After a sufficient trial of the preparation, Dr. Lawson concluded (*Practitioner*, xiv. 262) that its insolubility and the gastric derangement it causes render it ineligible as a medicine, and that its therapeutic value does not entitle it to rank with the other, soporific and calmative medicines which are analogous to it. It has usually been administered in sugar-coated pills, and in doses of from 2 to 5 grains (Gm. 0.10–0.30), repeated several times a day or oftener. Its insolubility and unpleasant taste and smell render any other liquid vehicle than oil inappropriate for its administration. A formula for an elixir is given above.

CANELLÆ ALBÆ CORTEX, Br.—CANELLA ALBA.

Canella, U. S., 1870.—*Cannelle blanche*, Fr.; *Weisser Zimmt*, *Weisser Canel*, G.

The bark of *Canella alba*, Murray, s. *Winterania Canella*, *Linné*, s. *Canella Winterana*, Gaertner. Woodville, *Med. Bot.* 237; Bentley and Trimen, *Med. Plants*, 26.

Nat. Ord.—Canellaceæ.

Origin.—The *white wood* or *wild cinnamon* tree is indigenous to many of the West Indian islands and the southern section of Florida. It grows to about 40 feet (12 M.), has evergreen, blunt, lanceolate leaves, pale violet-colored, highly aromatic flowers in terminal corymbs, and bluish-black subglobular berries, about $\frac{3}{4}$ inch (1 Cm.) long, and containing two to four angular and roundish reniform seeds. The silver-gray corky layer

of the bark is mostly removed by beating, and subsequent cutting before the bark is collected. The drug became first known in Europe in 1605.

Description.—The bark is in quills or half quills varying in length from a few inches to 2 or 3 feet (.6 or .9 M.), and in diameter from $\frac{1}{4}$ to $1\frac{1}{2}$ inches (6 to 38 Cm.). The external surface is of a pale yellowish-red color, with transversely elongated scars of the suberous warts, and occasionally with fragments of the gray corky layer and with whitish patches of the inner bark laid bare by the removal of the reddish layer; inner surface white, finely striate; fracture short, white, with numerous bright orange-yellow dots of resin-cells. The odor is agreeably aromatic, cinnamon-like; the taste aromatic, somewhat bitter, and biting.

Substitutions.—The bark of *Cinnamodendron corticosum*, *Miers* (Bentley and Trimen, *Med. Plants*, 27), a small tree of the same natural order as the preceding, is indigenous to Jamaica, and is there employed like *Canella alba*. It has oblong-lanceolate, acute leaves and red flowers in axillary clusters of two to four. The bark is of a ferruginous gray-brown, darker upon the outer surface, spotted by scars of the nearly circular suberous warts, smooth and finely striate upon the inner surface, and agreeing in odor and pungent taste nearly with the preceding. Both barks have been frequently sold as Winter's bark. *Cinnamodendron macranthum*, *Baillon*, of Porto Rico, yields a similar bark.

Constituents.—The analyses of Henry (1821) and of Petroz and Robinet (1822) proved the existence of volatile oil, resin, bitter principle, mucilage, starch, albumen, and salts. The *canellin* of the last-named chemists is identical with mannit, according to Meyer and Von Reiche (1843), who obtained 8 per cent. of it, and separated from the volatile oil eugenol, an oil having the odor of cajuput, and another fraction not further examined. From 0.5 to 0.94 per cent. of volatile oil and about 6 per cent. of ash, consisting mainly of calcium carbonate, have been obtained from the bark. The bitter principle has not yet been isolated. The cinnamodendron-bark has probably similar constituents, but contains in addition some tannin, which is not present in *Canella alba*.

Off. Prep.—*Vinum rhei*, *U. S.*, *Br.*

Medical Action and Uses.—*Canella* is tonic and stimulant, and may be employed to relieve simple gastric debility. It is seldom used alone, but rather along with bitter tonics and with purgatives that tend to debilitate, as scammony and jalap, or that have a local action which it is designed to increase, as in the case of aloes when given for *uterine disorders*. The *dose* in powder is from 10 to 40 grains (Gm. 0.60–2.50).

CANNABIS, *U. S.*, *Br.*, *P. G.*—CANNABIS.

Hemp, *E.*; *Chanvre*, *Fr.*; *Hanf*, *G.*

Cannabis sativa, *Linné*. Bentley and Trimen, *Med. Plants*, 231.

Nat. Ord.—Urticacæ, Cannabineæ.

Official Kinds.—1. CANNABIS AMERICANA, *U. S.*—American cannabis, American hemp, *E.*; Chanvre américain, *Fr.*; Amerikanischer Hanf, *G.*—*Cannabis sativa*, grown in the Southern United States, and collected while flowering.

2. CANNABIS INDICA, *U. S.*, *Br.*; Herba cannabis Indicæ, *P. G.*—Indian cannabis, Indian hemp, *E.*; Chanvre indien, *Fr.*; Indischer Hanf, *G.*—The flowering tops of the female plant of *Cannabis sativa*, grown in the East Indies.

Origin.—The hemp-plant is indigenous to Asia, from India north to Western China and the Caspian Sea; it grows likewise in tropical Africa. Having been cultivated from a very early period for its textile bast-fibres and its oily fruit, the cultivation has extended to most civilized countries. The plant grows spontaneously in Europe and North America, and has been naturalized in some parts of Brazil. It is an annual, with an angular roughish stem, 4 to 8 and even 10 feet (1.2, 2.4, and 3 M.) high, with opposite or the upper ones alternate petiolate and digitate leaves, composed of five to nine lanceolate or linear-lanceolate, acute, and serrate leaflets, and with dioecious flowers. The Indian plant has the lower leaves alternate, the stem is more branched, and the bast-fibres are coarser; but the characters vary and are not sufficiently important to constitute it a distinct species. The plant richest in resin grows at an altitude of 6000 to 8000 feet (1800 to 2400 M.).

Description.—The American hemp consists usually of the barren plant, which has the characters given above; the staminate flowers are in loose pedunculate, axillary panicles crowded near the summit, and composed of clusters of pedicellate greenish flowers having a deeply five-cleft perianth. The fertile plant has the pistillate flowers single or

in pairs, sessile, bracteate, and with slender protruding stigmas, the inflorescence forming erect, short, and compact spikes. The odor of the dry plant is heavy, the taste bitter and somewhat acid.

The Indian hemp found in the market is that known in India as *gunjah* or *ganja*, and in London and elsewhere as *ganza*; as collected, it consists of the tops of branches, which are 2 to 3 inches (50 to 75 Mm.) long, compressed, of a brownish-green color, with few leaves, a large number of female flowers, and some ripe or nearly ripe fruits, the whole more or less agglutinated by resin, but nevertheless quite brittle; odor narcotic, not unpleasant; taste bitter and slightly acid. In the bazaars it is also seen in bundles, which are composed of the upper branches, 2 to 3 feet (.6 to .9 M.) long, several inches in diameter, and showing more or less of the resinous exudation.

Another form is used in India under the name of *bhang* or *siddhi*, the *hashish* of the Arabs, which consists of leaves and small stalks coarsely broken and mixed with few fruits; it is smoked with or without tobacco, and is chiefly employed in the preparation of various electuaries and beverages. The resin is collected in India in a very primitive manner and impure condition, and is known as *charas* or *churrus*. It is either the dusty powder obtained on storing the dry plant, or by rubbing the fresh tops between the hands and scraping off the adhering resin, or by removing it from the leather garments of men who run through the hemp-fields brushing against the plants. The plants grown at an altitude of from 6000 to 8000 feet are stated to produce this resin, while those grown in the plains yield little or none.

FRUCTUS CANNABIS.—Hempseed, *E.*; Semences de chanvre, Chénevis, *Fr.*; Hanfsamen, *G.*—It is an akene about $\frac{1}{4}$ inch (3 Mm.) long, ovate, somewhat flattened, and somewhat two-edged: the pericarp is thin, hard, smooth, greenish or brownish, delicately veined, and contains a single greenish seed, the embryo of which has the radicle bent upon one of the cotyledons. The fruit is inodorous, and has an unpleasant, sweetish, and oily taste. By trituration with water it yields an emulsion.

Constituents.—*G.* Martius (1856) obtained from this plant, besides gum and sugar, nitrate of potassium and other salts and resinous matter; dried at 100° C. (212° F.), the herb yielded 18 per cent. of ash containing silica and phosphates as the main constituents. European hemp had been previously examined by Schlesinger and Bohlig (1840); both found considerable malic acid, and the latter 0.3 per cent. of a yellow aromatic oil having faintly narcotic properties. Personne (1857) claimed the volatile oil obtained from Indian hemp to be the sole active principle; he separated it into liquid *cannabene*, $C_{18}H_{20}$, and solid *cannabene hydride*, $C_{18}H_{22}$. According to Bohlig, the essential oil contains oxygen. After rectification over sodium it was found by L. Valente (1881) to have the spec. grav. .9292 at 0° C., to boil at 256° to 258° C. (493° and 496.4° F.), to be readily soluble in alcohol, and to be violently acted upon by bromine. The *hashisein* of Gastinel is merely the alcoholic extract of *gunjah* deprived of the principles soluble in water. The *cannabin* of T. and H. Smith (1846) is much purer; it is obtained by exhausting the *gunjah* with water and solution of sodium carbonate, then washing the residue with water, drying, exhausting with alcohol, treating the tincture with milk of lime, precipitating the lime with sulphuric acid, treating the filtrate with animal charcoal, filtering, concentrating, and precipitating by water; it constitutes a brown amorphous resin which burns without leaving any ash. Procter (1864) observed that the resin is converted by hot nitric acid into an orange-red substance resembling gamboge, and Bolas and Francis (1871) obtained from this residue *orycannabin*, $C_{20}H_{20}N_2O_7$, which crystallizes from methylic alcohol in large prisms. Preobraschensky (1876) claimed to have obtained *nicotine* from Bucharian hashish and from *gunjah*. Siebold and Bradbury (1881) failed, like other investigators, to obtain nicotine, but isolated from 10 pounds of *gunjah* about 2 grains of a volatile alkaloid, *cannabinine*, which forms a varnish-like mass of a coniine-like but less nauseous odor, sparingly soluble in water, and in this solution yielding with chlorine-water a white turbidity. Matthew Hay (1883) showed that *Cannabis indica* contains several alkaloids; the sulphate of one of these is soluble in alcohol. The alkaloid itself is easily soluble in water and in alcohol, more slowly soluble in chloroform and ether, and from the latter solution obtainable in needles. It does not show the color-reactions of strychnine, but resembles it in its physiological effects; hence the name *tetranocannabinine* is proposed for it.

The analysis of Bucholz, and the later one by Anderson (1855), failed to find in hempseed any other constituents than those common to oily seeds. The small quantity of resin has not been further examined; the protein compounds amount to 22 or 24 per cent. and the fixed oil to about 30 per cent. Berjot (1860) obtained 28, Cloëz (1865)

31.5, and Münch (1866) 35.5 per cent. of oil. *Oil of hempseed* is a drying oil, and has a greenish- or brownish-yellow color, a peculiar odor, and a mild taste; it is readily soluble in boiling alcohol, and when heated with one-fifth of its measure of soda solution spec. grav. 1.34 it acquires a yellowish-brown color and a thick consistence.

Off. Prep.—Extract. cannabis Indicæ fluid., *U. S.*; Ext. cannabis Indicæ, Tinct. cannabis (cannab. Indic.), *U. S.*, *Br.*

EXTRACTUM CANNABIS AMERICANA, Extract of American hemp. An alcoholic tincture of American cannabis evaporated to the consistence of an extract, *U. S. P.* 1870.

CANNABINE TANNATE, for which no formula has been published, is a yellowish-brown permanent powder, insoluble in water and ether, slightly soluble in alcohol, of a not unpleasant odor, and of a bitterish astringent taste; it is stated to be the tannate of a glucoside.

Physiological Action.—The action of American hemp is identical in kind with that of the East Indian species, but its activity appears to be less. Like some other narcotics, Indian hemp when given by the stomach to carnivorous animals produces its characteristic effects, but graminivorous animals and fish exhibit only vacillating movements and a dull aspect. Upon man its action varies with the individual's temperament and tendencies. Some it inspires with pugnacity, others it inclines to dreamy contemplation, to motiveless merriment, or to maudlin sensibility; some it makes unnaturally active and restless, and plunges others in a drowsy stupor; but more than any other agent, not even excepting belladonna, it perverts the natural perception of objects and their normal condition and relations. Time, distance, and sound are especially apt to form the subjects of the hallucinations caused by this drug. As in dreams, the events of days or weeks may be compressed into an actual period of a few minutes, objects near at hand may seem to form a limitless perspective, and whispered tones may have the reverberation of thunder. These and an infinite variety of fantastic pictures are evoked by smoking the drug, as it is generally employed in Asia, associated with opium. During its influence the physical condition of the experimenter exhibits changes in acceleration of the pulse, warmth of skin, restless muscular movements, more or less insensibility to touch and pain, and sometimes impaired power of locomotion, the limbs feeling as if weighted with lead. In one reported case a diffused vesicular eruption was attributed to this medicine (Hyde). It does not increase, but, on the contrary, impairs, the venereal propensity and power. The habitual use of cannabis in excessive doses causes the face to become bloated, the eyes injected, and the limbs weak and tremulous; the mind grows imbecile, and ultimately death by marasmus is apt to occur. Acute poisoning by large doses is marked by various and dissimilar symptoms in different cases. In some there is loss of consciousness, with collapse or stupor, insensible pupils, a pale, clammy, and insensible skin, extreme debility, and a small, feeble pulse. In others a cataleptic condition, spasms, or convulsions occur, and in all there is marked anæsthesia. The last-named effect led to the use of cannabis by the Chinese in certain surgical operations.

Medical Uses.—The effects of cannabis as just described would not suggest its employment in *tetanus*, and yet in the traumatic variety of a disease notoriously of fatal issue its virtues have been demonstrated by physicians entirely competent to test them. In India it has been successfully employed by causing the patient to smoke *gunja*, or else the dried leaves of cannabis, almost continuously. It is of comparatively little use in *neuralgia*, *rheumatism*, *epilepsy*, or *chorea*. In a case of *chorea* following concussion of the spine it seemed to promote the cure (Siegfried, *Hygien. and Med. Rep. U. S. Navy*, 1879). Its anæsthetic virtues are shown by its allaying the intense itching of *eczema*, so as to permit the patient to sleep; it is said to have been used with advantage to diminish *hallucinations* of sight and hearing in certain forms of *insanity* and in *delirium tremens*; but in such sensorial aberrations its action is by no means uniform. It is alleged that extract of cannabis used habitually in the dose of one-third of a grain twice a day will prevent or greatly mitigate recurrent *headache*, or *migraine*. During the attacks the dose should be increased to half a grain (Gm. 0.03) or more. It seems to be peculiarly efficient in various conditions of the brain involving a positive or relative anæmia of that organ, such as *delirium* and *sleeplessness after fever*, *softening of the brain*, *thickening of the meninges*, *obstinate nervous vomiting*, etc. Frommüller alleges that "tannate of cannabin" is a reliable hypnotic in the dose of from 2 to 10 grains, but this statement is not confirmed by Ewald, Leyden, and others. Cannabis appears capable, directly or indirectly, of causing uterine contraction, as in many cases of *uterine hæmorrhage*; and it is also said to provoke this act during *labor* with as much energy as ergot, but its effects are less persistent. The dose of extract of cannabis is from $\frac{1}{2}$ grain to 2 grains (Gm.

0.03–0.12), but since the preparation is often quite inert, none should be used medicinally that has not previously been tested. Lemon-juice tends to neutralize its effects. Tobacco and coffee are said to increase and prolong the action of the drug.

CANTHARIS, U. S., Br.—CANTHARIDES.

Cantharides, P. G.; *Muscæ Hispaniæ*.—Spanish flies, E.; *Cantharides*, Fr.; *Spanische Fliegen*, *Canthariden*, *Kantheriden*, G.

Cantharis vesicatoria, De Geer (*Hist. des Insectes*), s. *Lytta vesicatoria*, Fabricius, s. *Meloe vesicatorius*, Linné. The beetle collected chiefly in Hungary and Southern Russia.

Class Insecta; Order Coleoptera—Beetles.

Description.—The so-called Spanish fly is indigenous to Southern and Central Europe, and is found eastward as far as Western Asia; it frequents chiefly trees and shrubs of the Oleaceæ and Caprifoliaceæ, such as the ash, lilac, elder, and honey-suckle. The beetle is from $\frac{1}{2}$ inch to $1\frac{1}{2}$ inch (12 to 30 Mm.) long and $\frac{1}{3}$ to $\frac{1}{2}$ inch (5 to 8 Mm.) broad, flattish-cylindrical in shape, of a shining brass or copper-green color above and below, and finely punctate above. Head subcordate, with a longitudinal furrow; eyes two, lateral; antennæ filiform, of eleven joints, the lowest three green, the upper black; thorax of the same width as the head, longitudinally channelled; wing-cases covering the body, with two fine longitudinal ridges; wings ample, membranous, brownish-transparent; tarsi of the hinder legs with four, and of the others with five, joints; claws bifid. *Cantharides* have a strong and disagreeable odor, and yield a brown-gray powder intermixed with green shining particles.

Cantharis vesicatoria.

Collection and Commerce.—*Cantharides* are collected early in the morning by spreading cloths under the trees and shrubs, which are then shaken or beaten with poles; the insects are plunged into hot water, afterward spread out and dried. A better method for killing them is by means of a little chloroform, ether, oil of turpentine, or carbon disulphide after enclosing them in a tight vessel. They are collected for exportation in Spain, Italy, Hungary, and Southern Russia, and packed in boxes and casks. Those coming from Russia are of a copper color, larger than those of Western Europe, and are most esteemed. 6000 pounds of *cantharides* were imported in the year 1867, and 5000 pounds in 1879, but the importation usually reaches 14,000 to 19,000 pounds per annum, including Chinese blistering-beetles.

Allied Species.—Several of the American species allied to the Spanish flies have been found to possess efficient vesicating properties, and among these may be mentioned: *Cantharis vittata*, or potato-fly, which has a black thorax and wing-cases, with three yellow stripes upon the former, and the latter margined with yellow and with a yellow stripe down the middle; *C. cinerea*, black, closely punctured, and covered with ash-gray hairs; *C. marginata*, elytra black, with the margin ash-colored; *C. atrata*, only about $\frac{1}{2}$ inch long, uniformly black. Attention has also been called among others to *C. Nuttalli*, which resembles the Spanish fly, but has golden-purple wing-cases striped with green; it is very abundant in Kansas and Colorado. (An interesting paper, treating of many of the North American blistering-beetles and of the development of *Meloe*, by Mr. W. Saunders, may be found in the *Proceedings of the American Pharmaceutical Association*, 1876, p. 505.)

MYLABRIS CICHORII, Fabricius, and *M. PHALERATA*, Pallas, two vesicating insects indigenous to Eastern and Southern Asia and to some parts of Africa, have recently been imported as *Chinese blistering-flies*; the insects are black, with two orange-colored bands and two spots of the same color upon the wing-cases. They yield a blackish-gray powder destitute of the green glossy particles observable in powdered *cantharides*, and are quite efficient as a vesicant. The East Indian *Lytta Gigas*, Fabricius, which is longer than *cantharides* and of a purplish-blue color, has likewise been occasionally met with in commerce.

Preservation.—All blistering-beetles should be kept in a well-dried condition and in close vessels, protected by a little camphor, ether, chloroform, or oil of turpentine against the attacks of mites and of small beetles and their larvæ.

W. E. Saunders (1883) finds the vapors of chloroform to afford better protection than camphor. The blistering principle resides mainly in the soft parts of can-

Cantharis vittata.

Mylabris cichorii.

idea which has been sometimes advanced, that they increase in strength when thus attacked, is erroneous.

Adulterations.—Cantharides are occasionally mixed with beetles of a similar color which have been collected with them, but evidently not for fraudulent purposes. The shape and color of the insects prevent them from being adulterated. But powdered cantharides are said to be sometimes ground together with euphorbium. Adulterations are best recognized by determining the amount of cantharidin by the modifications of Procter's process mentioned below, sometimes also by the amount of ash. "When incinerated, cantharides should yield not over 8 per cent. of ash."—P. G.

Constituents.—Robiquet's analysis (1810) indicated the presence of cantharidin, free acetic and uric acids, fatty matters (stearin, palmitin, and olein, according to Goessmann), yellow viscid matter soluble in water and alcohol, a yellow substance soluble in ether and alcohol, black extractive, and magnesium and calcium phosphates. E. Dietrich (1883) found also notable quantities of formic acid. Pocklington (1873) regards the green coloring matter as chlorophyll. *Cantharidin*, $C_{10}H_{12}O_4$, is most readily obtained by Procter's process (1851), as modified by Mortreux (1864) and Fumouze (1867): this method consists simply in exhausting the powder with chloroform, evaporating spontaneously, and freeing the residuary crystals from fat and coloring matter by washing them with bisulphide of carbon. Galippe (1875) recommends the substitution of acetic ether for the chloroform. Beguin gives preference to the same menstruum, and believes that the solvents mentioned completely extract the cantharidin, and that therefore it cannot be contained in the beetles partly in combination, as was stated by Bluhm (1865), Renard (1871), and others. But Dragendorff (1867, 1872) showed that the yield of cantharidin may be increased by treating the powder first with an alkali, and supersaturating afterward with hydrochloric acid before exhausting the cantharidin; and E. Dietrich (1880) found it of advantage to subject the alkaline liquid to dialysis. The experiments of R. Wolff (1877), made with *Lytta aspersa* of South America, indicate that ammonium compounds may be present and gradually increase in quantity through the agency of moisture and the magnesium salts of the beetles, whereby sparingly soluble compounds are formed; all of which, as far as examined, are decomposed by acetic ether, with the liberation of cantharidin; hence the larger yield when old cantharides are treated with this menstruum. The amount of cantharidin found by different authors in cantharides varies between 0.17 and 0.57. Boiraux and Léger (1875) obtained as much as 1 per cent. by using hot coal-oil (boiling between 80° and 120° C.). W. R. Warner (1856) obtained from *C. vittata* 0.40, L. Fahnestock (1879) from the same species by Dragendorff's method 1.3 per cent.; R. Wolff from *Lytta aspersa* 0.85, Prestat (1876) from *Mylabris interrupta* of Algiers 0.858, Maisch (1872) by Fumouze's process from Chinese beetles 1.016 per cent., and L. Fahnestock (1879) 1.25 per cent. from the same lot of beetles after they had been kept for six years, and with the use of Dragendorff's process; Warner obtained only 0.43 per cent. That cantharidin is with difficulty obtained pure from old cantharides was also shown by Fahnestock (1879). According to Nentwich (1871), full-grown cantharides only are vesicating.

Cantharidin crystallizes in colorless prisms and scales, and is soluble in alcohol, methylic alcohol, ether, chloroform, acetic ether, glacial acetic acid, and fixed and volatile oils, but insoluble in carbon disulphide and in petroleum benzin. Dietrich considers formic acid the best solvent, and states that cantharidin dissolved in this acid may be distilled. It is rendered soluble in water through the yellow viscid matter in cantharides (Robiquet), which we find to be partly precipitated by basic lead acetate and mercuric chloride. But, according to Renard, hot and cold water dissolves nearly $\frac{1}{3}$ and $\frac{1}{5}$ per cent. of cantharidin, and this vaporizes when distilled with water, more particularly with the first portions—with chloroform even at 60° C., and in the dry state at and above 85° C. (185° F.). When dry it fuses near 210° C. (410° F.), and sublimes more freely at that temperature, condensing again in glossy prisms or needles. It unites with bases after assimilating H_2O , forming salts, *cantharidic acid* having the composition $C_{10}H_{14}O_5$, but on being decomposed by an acid cantharidin is again separated (Dragendorff, 1867). Krafft (1877) gives the formula $C_{20}H_{24}O_8$ to cantharidin, and states that the latter, heated with hydriodic acid spec. grav. 1.8, is gradually converted into the monobasic *cantharic acid*, which has the same composition, is crystalline, soluble in 120 parts of cold and 12 of boiling water, sparingly soluble in ether, and not vesicating when its glycerin solution is applied to the skin.

Off. Prep.—Acetum cantharidis, Br.; Ceratum (emplastrum) cantharidis, Charta cantharidis (epispastica), U. S., Br.; Ceratum extr. canthar., Collodium cum cantharide,

U. S.; Emplast. picis cum cantharide (calefaciens), *U. S.*, *Br.*; Linim. cantharidis, *U. S.*; Liquor epispasticus, *Br.*; Tinctura cantharidis, *U. S.*, *Br.*; Unguentum cantharidis, *Br.*

Other Insects.—Only two insects are now official in the *U. S.* and British Pharmacopœias, *Cantharis* and *Coccus*. Some European pharmacopœias recognize also the *red ant*, *Formica rufa*, *Linne*, which belongs to the order Formicidæ, and is used in preparing a spirit (see *ACIDUM FORMICUM*) and a tincture. The latter, *tinctura formicarum*, is made by digesting 2 parts of fresh and bruised ants in 3 parts of alcohol, and has a brown color.

Recently an insect of the order Orthoptera has been recommended—*BLATTA* (*PERIPLANETA*, *Burmeister*) *ORIENTALIS*, *Linne*; Cockroach, *E.*; Bête noir, *Panetière*, *Cafard*, *Fr.*; Schabe, *G.*—It is a native of Asia, but now found in most parts of the civilized world. It is dark-brown, about 1 inch (25 Mm.) long, has a flat broad body, the extremity of which is furnished with two conical appendages; the antennæ are long and filiform, the legs thin but strong, and the wings lie straight on the back, covering the greater part of the body of the male, but being quite short in the female. The cockroach is nocturnal in its habits and has a disagreeable sickening odor. Bogomolow (1876) announced the isolation of the active principle *antihydropin* in a crystalline form, but has not published the process for obtaining it.

Physiological Action.—*On Animals:* Cantharides given to dogs in large doses cause vomiting, debility, dilated pupils, pain, bloody urine and feces, coldness, convulsions, and death. In doses not fatal irritation of the sexual organs is manifested. Injected into the veins, the symptoms are essentially the same. Half a grain of cantharidin used in this manner killed a dog in half an hour, and one-seventh of a grain destroyed a cat in the same time. After death from cantharides vascular injection of the intestine, the kidneys, and the bladder is found.

On Man: Internally, if the quantity be large, cantharides occasion a burning heat in the throat, stomach, and bowels, cause nausea and vomiting, often of blood, and produce fibrinous and sometimes bloody stools, griping, and tenderness of the abdomen. With such symptoms death may take place. If there is time for the absorption of the cantharidin, there is also strangury, with burning pain in the kidneys and bladder; the urine may at first be increased, but soon grows scanty, albuminous, or bloody; the local irritation is apt to occasion erection of the penis; sometimes, though rarely, erotic excitement and seminal emissions occur, and in the female genito-urinary excitation, which may induce abortion. Gangrene sometimes attacks the genitals. It is said that venereal excitement is more apt to follow the action of cantharides in substance than that of cantharidin, and the difference is ascribed to an essential oil which the former contains, and which gives them their characteristic nauseous and pungent odor. The general symptoms of cantharidal poisoning consist of a frequent and small pulse, hurried breathing, vascular injection of the face, heat of skin, thirst, pain in the head, delirium, trembling, tetanic spasm, and coma. The smallest fatal dose of cantharides on record is 24 grains, but the patient was a pregnant female, who aborted. An ounce of the tincture has been fatal to a boy of seventeen. Cantharidin does not appear to stimulate so energetically when taken internally; indeed, some Italian writers declare it to be a direct and powerful sedative of the nervous and circulatory systems. Several cases of poisoning by cantharidal collodion are recorded. In one case 15 drops of the preparation were taken by a woman who suffered chiefly from pain, strangury, and albuminous urine (*Phila. Med. Times*, iv. 312). In another case a man swallowed about 8 ounces of strong alcohol and half an ounce of sulphuric ether holding in solution half an ounce of cantharidal collodion. About 4 hours afterward he began to pass urine, and during the following 6 or 7 hours he discharged nearly 2 quarts; then it became scanty, glutinous, and bloody. He had severe pain over the kidneys, and also in the course of one ureter, and in the bladder. The urine was scalding, and there was a burning pain in the abdomen. The pulse gradually became small and the hands and feet cool, and death occurred in 35 hours (*Boston Med. and Surg. Jour.*, Jan. 1880, p. 108). After death from cantharides the gastro-intestinal and urinary mucous membranes are congested, bloody, inflamed (with exudation), or gangrenous. The kidneys are sometimes enlarged and engorged, and offer the signs of parenchymatous and desquamative nephritis, but chiefly of the latter (*Eliaschoff, Virchow's Archiv.*, xciv. 323; *Aufrecht, Pathologische Mittheil.*, ii. 32); the bladder contains blood, while its lining membrane is red, and presents blebs, pseudo-membranes, and sometimes ulcers. Applied to the skin in cerates, ointments, etc., or as cantharidin, this agent produces a stinging and burning pain, with redness, followed by vesication. The serum contained in the elevated cuticle is pale-yellow, alkaline, and albuminous; the chorion is pale-red, and its papillæ are prominent, or, if the action has been energetic, the chorion is highly inflamed and may be coated with a fibrinous

layer. When a blister is very large and long applied, it is apt to produce strangury, and the urine is then covered with an albuminous pellicle. It may also cause general nervous excitement and fever, inflammation of the lymphatics and their glands, or a diffuse erythema, and even gangrene of delicate parts or of such as are weakened by blood diseases. Hence a blistering plaster of large size should rarely be kept upon the skin until complete vesication occurs. Cantharidin does not appear to cause toxic effects as readily as cantharides.

Medical Uses.—*Internally*: Cantharides in the form of the tincture have been given in low forms of *fever*, and in cases of exhaustion from protracted *hectic*, with alleged advantage, but there is nothing to render this method eligible. The same is true in regard to *dropsy* and chronic *bronchitis*. In *scaly diseases of the skin* they have been found very useful, and should not be forgotten when arsenic and the application of tar, etc. have failed. In various forms of *debility of the bladder*, such as produce incontinence of urine in children and old men, and in the latter *dysury*, this medicine has been often efficient. Sometimes, indeed, when directly injected into the urethra, long-standing *gleets* have been cured by it, and also by its internal administration. In chronic *vesical catarrh* it deserves more confidence than it is apt to receive. *Diabetes insipidus* has been arrested by it. In all of these cases, except the last, it acts by producing a substitutive irritation. Before the pathological conditions which produce *dropsy* were recognized, a certain number of cases of this affection were recorded as having been cured by cantharides. Richter restricted the use of the medicine to cases distinguished by a torpid state of the system; Ferriar applied it to the cure of scarlatinous dropsy; and it was recommended by Lieutaud and by Blackwall (STILLE, *Therapeutics*, 4th ed., ii. 427). More recently Grain-gier Stewart (1871) mentioned the tincture of cantharides as a good stimulant diuretic in the later stages of the inflammatory form of Bright's disease; but Dickinson (1868) spoke of it unfavorably. E. Wagner (1882) referred to it, along with sabina, as possibly dilating the renal capillaries. In 1884, Dr. Bruen claimed that the tincture of cantharides acts favorably in chronic catarrhal nephritis combined with some interstitial process and associated with more or less cardiac hypertrophy, especially when given along with digitalis. He also stated that in several cases of *cardiac dropsy* "it very constantly increased the urinary secretion, forming a valuable adjuvant to digitalis" (*Phila. Med. Times*, xiv. 275). It has usually been held that digitalis is not adapted to the treatment of cardiac hypertrophy, except when it is associated with predominant dilatation. Its irritant action upon the pelvic organs is illustrated by its use in *amœorrhœa* depending upon atonic conditions, and in passive *seminal emissions* of the same nature.

Externally, the uses of cantharides, especially in blisters, are very numerous. They are employed—1st, to stimulate the whole or a particular part of the system; 2d, to promote the absorption or prevent the accumulation of inflammatory exudations; 3d, to recall suppressed discharges; 4th, to act as a depletory; 5th, to promote the cure of internal diseases by counter-irritation of the skin. Their direct remedial influence by stimulation is seen in cures of indolent *ulcers*, *fistula*, and several inveterate diseases of the skin, as *lepra*, *psoriasis*, and *lupus*, and even of certain acute ones, as *zona* and *erysipelas*. Blisters have been used with striking effect to prevent the increase and hasten the cure of *boils* and *carbuncles*, by applying them so as to cover the whole indurated spot and allowing them to vesicate fully. To be successful this method must be employed early. Liniments containing tincture of cantharides are among the best means of curing *alopecia*. The revulsive operation of blisters is the one most usually invoked, and, on the whole, the most useful. Wherever there is a local tendency to congestion the timely and due application of a blister modifies and may arrest it; thus it may prevent serious *congestion of the brain*, or its increase if already existing, or its consequences through effusion if this have occurred, by depleting the neighboring skin, and probably by a reflex action upon the vaso-motor nerves. These consequences include *paralysis* and other effects of *congestion*, *hæmorrhage*, and allied conditions of the brain and spinal cord. Evidently, vesication should not be made in their acutest stage, and its benefits are relatively small when the state has become chronic; in the former it over-stimulates, in the latter its stimulation is useless. Many cases of *dropsy of the brain* have been palliated by blistering the scalp; many of *general dropsy* by blisters cautiously applied to the legs; many also of *hydrocele*, of *hydrarthrosis*, and, most of all, of *chronic pleurisy*, in which no medical means are more efficient than a succession of large blisters. A similar action is no doubt exerted by blisters when applied along the under surface of the penis for *gleet* and to the sacrum for *leucorrhœa*, to prevent *abortion*, to relieve *dysmenorrhœa*, and to hinder the suppuration of deep-seated *buboes* and other gland-

ular inflammations. In the last-mentioned cases, if the inflamed organ is very superficial or the action of the blister is deep, suppuration will be hastened. Abscesses of various sorts may be conveniently evacuated by blistering, and especially cold abscesses, if the skin over them is already thin.

The action of blisters in *fevers* is probably both stimulant and revulsive, and to a certain extent depletory. The clinical facts of the matter are simply these: that blisters, especially on the nape of the neck, are generally useful in *typhus* and *typhoid* fevers, whether the condition be one of excitement or of coma or denote a tendency to the one or the other state. They are not equally beneficial under analogous conditions in scarlatina or variola, or during acute inflammations of the lungs, heart, or bowels. Their stimulant action is the one most frequently sought—i. e. when the symptoms are moderately comatose—in which case the vesicant should not remain applied longer than from 2 to 4 hours, its fuller effect being secured by a dressing of simple ointment or a poultice. In cases of profound stupor a more sustained operation is necessary. When coma is due to an *apoplectic* condition, whether hæmorrhagic or only congestive, the active depletory operation is to be secured by a more prolonged application of the blister, and, if necessary, to the scalp as well as to the back of the neck. In such cases also the discharge should be maintained by means of stimulant dressings. In all forms of inflammation of the *eyes* blisters are invaluable as revulsives, applied to the *nuchæ*, behind the ear, or on the forehead. The utility of blisters in *acute* inflammation of the pleura and of the lungs (*pleurisy* and *pneumonia*) depends upon their being applied long enough only to vesicate superficially and so as to cover a large portion of the affected lung. Smaller blisters may relieve a stitch in the side, but will not so distinctly influence the progress of the inflammation within, as denoted by a diminution of the cough, oppression, and fever. Small blisters are of essential use in those limited pleurisies which occur during chronic phthisis, and they should not be disregarded in analogous pneumonias. In *pericarditis* blisters should never be omitted; they allay pain, probably limit the effusion, and certainly promote its absorption. The revulsive action of blisters is also a precious resource in the treatment of *phlegmasia alba*, of *phlebitis*, and especially of *chronic fluxes of the bowels*. Nothing is more efficient in the last than a succession of large and superficial blisters. The treatment of acute articular *rheumatism* by blisters applied upon the affected joints has been attended with a large degree of success, but it is doubtful whether the benefit is due so much to a revulsive or counter-irritant operation as to the alkalinity of the secretions induced by blistering. As the use of alkalis internally and locally usually cures acute articular rheumatism, it does not seem worth while to employ a remedy which accomplishes no more than they, while it inflicts much pain. In cases of retrocedent rheumatism or gout it has been advised to blister the joints last affected, but less severe revulsives are doubtless as useful. Of all the local methods of treating *neuralgia*, that by blisters is the most efficient. It consists in applying small blisters over the superficial portions of the affected nerves, especially where they emerge from bony or tendinous openings or distribute their terminal branches to the skin. The vesication should be slight when the nerves are superficial, energetic when the trunks lie deep. The nerves of the head, face, and chest require the former method—the sciatic nerve the latter. In cases suitable for superficial vesication the operation should be repeated as often as the skin heals if the pain continues to return; when the nerves lie deep, the discharge from the blistered surface should be constantly maintained until the cure is perfect. *Spinal irritation*, so called, is most frequently a true neuralgia, but is sometimes also a constant aching of the muscles along the spine, produced by nervous exhaustion. It may be relieved by superficial blistering, and by other local stimulants, including electricity, provided a suitable regimen by rest and nutritious food are at the same time employed. The revulsive action of blisters is also employed in *convulsive disorders* for the purpose of reducing the morbid irritability of the cerebro-spinal centres. It has long been used upon the spine in *tetanus*, and with unequivocal advantage, and in all diseases attended with tetanoid rigidity or convulsions. Its advantages are hardly inferior in all cases of *paralysis* that depend upon congestion or inflammation of the spinal cord or its membranes. It is notably a valuable element of the treatment in *epileptic meningitis* when the phenomena dependent upon nervous disorder exceed those which depend upon alterations of the blood. The blisters should cover the occiput and extend along the spine to the end of the cervical vertebræ at least, and should vesicate thoroughly. *Spasms* of particular muscles are often moderated by blistering the affected part, as in *scrivener's spasm*, and the nutrition of *wasting muscles* after rheumatism, injuries, etc. is generally improved by a course of blistering. *Vomiting* is often arrested by blistering the epigastrium.

A blister should, in general, be applied as near as possible to the part which it is intended to benefit. It is usually undesirable to allow it to remain upon the skin until vesication has been accomplished. *Usually from 3 to 6 hours, or until vesication commences, will be long enough.* It will act more promptly if the part has first been cleansed with warm water and soap and bathed with vinegar. Fever renders the action of blisters more rapid, and coldness and nervous insensibility of the skin retard it. They act more promptly when the skin is delicate, hence more so in children and females than in other persons; consequently, especial care should be used to prevent their excessive action in such patients, either by diluting the blistering cerate or by interposing a piece of tissue-paper or fine muslin between the plaster and the skin. If it is desired to heal a blister soon, the raised cuticle should be cut freely, so as to evacuate the serum, and a dressing of carded cotton applied and secured with a roller. If it is intended to maintain the discharge, the cuticle should be removed, and a dressing, first of simple cerate, and within 24 hours one of basilicon ointment, applied. Under such stimulation the discharge grows purulent, and may be maintained by savine cerate or mezereon ointment. As a general rule, blisters should be very cautiously employed in old and in young persons; in the former they act slowly and often leave intractable sores; in the very young they are prone to excite excessive reaction and occasion gangrene. During epidemics of diphtheria blisters are very apt to become covered with false membrane; during other epidemics they are likely to be attacked with erysipelas or with gangrene, or to be followed by abscesses or by an eruption of boils. To prevent the strangury which plasters of cantharides frequently cause, the most usual method is to sprinkle the surface of the plaster with finely-powdered camphor or to brush it over with tincture of camphor. The efficacy of this method is very doubtful. It has been alleged that if the plaster be sprinkled with bicarbonate of sodium mixed with coarsely-powdered cantharides, the apprehended effect will not take place. For internal administration the tincture is the only preparation of cantharides which it is prudent to use.

Poisoning by cantharides recently taken should be treated by a vegetable emetic, with copious draughts of warm water, and afterward by the free use of mucilaginous or albuminous liquids. But chloroform and the fixed oils, which dissolve the active principle of cantharides, should not be administered. General warm baths and emollient cataplasms on the abdomen should be used, and opiate enemata.

Blatta orientalis, or common cockroach, was anciently employed in medicine. An oily decoction of these insects was used to cure warts, scaly eruptions, indolent ulcers, contusions, boils, etc. Internally, they were given along with resin for the relief of dyspnoea (Pliny). Quite recently (1878) in Russia they have been employed in *albuminuria*. They are said to diminish the quantity of albumen, increase the perspiration and urine, remove the attendant dropsy, and neither to impair the digestion nor irritate the kidneys. In other forms of dropsy they are reported to have exhibited remarkable diuretic powers. More recent statements of the use of this agent in Russia appear to confirm the belief in its diuretic powers in dropsy (*Med. Record.*, xvii. 682). But Paul, having fully tested it clinically, concluded that it has no medicinal effect whatever (*Bull. de therap.*, xvi. 429, 473). Stanislas Martin endeavored to discern in the insect the cause of the virtues attributed to it, but he could extract from it only a stinking fat (*Bull. de therap.*, xvi. 168). The daily dose was from 4 to 5 grains (Gm. 0.25–0.30) of the powder obtained from the dried insect.

Enas aser, a coleopterous insect that abounds in Spain, is claimed to possess over cantharides the following advantages: it is cheaper; it acts without appreciable pain; it is equally powerful, and does not irritate the urinary organs (*British Med. Jour.*, May 20, 1882).

Red ants were formerly used medicinally. A large number of them, enclosed in a linen bag, were infused in boiling water, which, with the bag, was then added to local or general baths in the treatment of chronic gout and rheumatism. The affected foot or hand was sometimes subjected for several hours to the action of the ants by being thrust into their hills. Internally, a tincture of domestic manufacture was given, and which was made by the prolonged infusion of a large amount of ants in an equal quantity of brandy. An officinal *spiritus formicarum* was formerly in common use, and is retained in the last edition of the German Pharmacopœia (1883). It was given internally, in doses of from 20 to 50 drops, in nervous and paralytic affections, and also applied by friction. An oil made by macerating living ants in almond oil was used for similar external purposes.

CAPSICUM, U. S.—CAPSICUM.

Capsici fructus, Br.; *Fructus capsici*, P. G.; *Piper Hispanicum*.—*Capsicum*-fruit. *Cayenne pepper*, *African pepper*, *Pod pepper*, E.; *Capsique*, *Piment des jardins*, *Piment rouge*, *Poivre de Cayenne*, Fr.; *Spanischer Pfeffer*, *Schotenpfeffer*, G.

The dried fruit of *Capsicum fastigiatum*, *Blume*. Woodville, t. 80; Bentley and Trimen, *Med. Plants*, 188, 189.

Nat. Ord.—Solanaceæ.

Origin.—Several species have long since been cultivated in tropical countries, and since the early part of the sixteenth century also in Europe; they are supposed to be indigenous to South and Central America, and to have been introduced into the East Indies by the Portuguese; also in Africa. The plants of this genus are herbaceous or shrubby, have the leaves alternate or on the flowering branches sometimes opposite, petiolate, entire or wavy-margined, and produce from the forks of the branches from one to three pedunculate flowers with a rotate, five-lobed, yellowish, whitish, or reddish corolla, and yielding an incompletely two- or three-celled berry containing numerous flat seeds. In the course of time many varieties have been produced through cultivation. The average annual importation into the United States during seven years ending 1882 was 81,977 pounds of the fruit and 13,295 pounds of powdered capsicum, the highest being of the former 353,683 pounds in 1876, and of the latter 25,352 pounds in 1881.

Description.—*C. FASTIGIATUM*, *Bl.*, is a small shrub bearing in each fork two or three fruits which are $\frac{1}{2}$ to $\frac{3}{4}$ inch (12 to 18 Mm.) long, about $\frac{1}{2}$ inch (5 Mm.) thick, of a conical-oblong shape, supported by a flattish cup-shaped five-toothed calyx, bright-scarlet in color; become shrivelled on drying, and consist then of a thin, translucent, and fragile pericarp enclosing two cells containing, attached to the thick central placenta, numerous flat, reniform, yellowish seeds, which are about $\frac{1}{8}$ inch (3 Mm.) in diameter and have a semicircular embryo enclosed in a fleshy albumen. The odor of the fruit is peculiar, its taste extremely hot and biting. This kind is known in commerce as *African* or *bird pepper*, and in Great Britain as *chillies* and *Guinea pepper*. It is the only kind permitted by the British and the U. S. Pharmacopœia.

C. FRUTESCENS, *Linne*, has a similar fruit, which is ovate-oblong, $\frac{1}{2}$ to $\frac{1}{2}$ inch (8 to 12 Mm.) long and $\frac{1}{8}$ or $\frac{1}{4}$ inch (3 or 4 Mm.) thick.

C. ANNUM, *Linne*, is an herbaceous annual, and is extensively cultivated in the temperate zone. The fruit grows singly in the forks of the stem, is much larger than the preceding, and varies in shape between straight or curved, conical, erect, or pendulous, and more or less globular; it attains a length of 2 to 4 inches (5 to 10 Cm.), a thickness of 1 to 1½ inches (25 to 38 Mm.), is sometimes yellow, but generally red, and after drying brownish; otherwise it resembles the preceding. The fruit is known in England as *pod pepper*, but also sold as *chillies*, and is the kind recognized by the German Pharmacopœia.

C. LONGUM, *Fingerhuth*, *C. grossum*, *Willdenow*, *C. cordiforme*, *Miller*, and other nominal species, are now usually regarded as varieties. Some cultivated varieties, like much of the *paprika* used in Hungary, were shown by H. B. Brady (1880) to be almost destitute of pungency.

The fruits of *C. cerasiforme*, *Willdenow*, of the size and shape of a cherry, and of *C. chlorocladum*, *De Candolle*, small and oblong, are occasionally, though not often, met with.

The outer layer of the pericarp of capsicum-fruit consists of several rows of tangentially elongated cells with irregularly thickened walls, and containing the granular red or yellow coloring matter. This is followed by a thicker layer of thin-walled parenchyma and thin spiral vessel, and by the inner membrane, consisting of a single row of flat irregularly thick-walled cells.

Powdered capsicum is of a dark orange-red color, is very sternutatory and irritating, and, particularly when prepared from the second species, is not unfrequently attacked by insects.

Constituents.—Since the analysis made (1816) by Bucholz and Braconnot the name of *capsicin* has been given to various liquid or soft preparations, all of which were more or less impure, though containing the fiery principle, which at last was isolated by J. C. Thresh (1876), who found it to be a crystallizable body which has been called *capsaicin*, is with difficulty obtained pure, and, according to Dr. Buri, has the composition $C_9H_{14}O_2$. It is present in small quantities only, and intimately associated with a red

fatty matter which consists chiefly of palmitic acid. Buchheim's *capsicol* (1873) is a red oily liquid containing the active principle, which may be isolated by treating the oleoresin prepared with ether or benzin with weak potassa solution, passing carbonic acid gas through the watery liquid, and purifying the precipitate by recrystallization. Capsaicin is colorless, melts at 59° C. (138.2° F.), volatilizes at 115° C. (239° F.) with extremely irritating vapors, and dissolves in alcohol, fixed oils, ether, amylic alcohol, benzol, and alkalies, but slowly in turpentine, carbon bisulphide, and petroleum. It yields crystalline compounds with barium, calcium, and mercury, and when oxidized with nitric acid produces an oily body, oxalic and succinic acids, and another crystalline acid whose nature has not been determined. The red coloring matter of capsicum is but slightly soluble in boiling alcohol, but dissolves readily in oils, sulphide of carbon, petroleum, amylic alcohol, ether, and chloroform. Felletár (1868) isolated from capsicum a volatile alkaloid which has the odor of conine, but was found to differ from this alkaloid by Dragendorff (1871) in the different shape of the crystals of its hydrochlorate, and from lobeline in not being colored by Fröhde's reagent. The odor of capsicum is in part due to a volatile oil consisting chiefly of stearopten and having a parsley-like odor; from 100 pounds of capsicum Flückiger obtained only .02 Gm. (*Pharmacographia*).

Off. Prep.—Extract. capsici fluid., Oleoresina capsici, *U. S.*; Tinctura capsici, *U. S.*, *Br.*

INFUSUM CAPSICI.—Infusion of capsicum, *E.*; Tisane de capsique, *Fr.*; Spanisch-pfeffer-Aufguss, *G.*—Macerate for 2 hours capsicum 240 grains in boiling water a pint, and strain.—*U. S.* 1870.

Physiological Action.—Capsicum is an irritant and a local stimulant. Applied to the skin, it causes redness, and if continuously applied may ultimately produce vesication. In proper quantities it excites a grateful warmth in the throat and stomach and quickens the appetite and digestion. It tends to prevent the flatulence occasioned by vegetable food, and for this purpose is largely used as a condiment in hot climates. In large doses it causes a general glow, with thirst, but does not raise the temperature or accelerate the pulse. If too lavishly used, it sometimes brings on torpor of the digestive functions, but often it seems not to be injurious. These conclusions have been fully sustained by the experiments of Höggyes on man and animals (1878), which show that capsicum and capsicol produce only a local and transient irritation of the skin and mucous membrane, and that when used as a condiment cayenne pepper acts chiefly by stimulating the salivary and gastric glands and promoting the peristaltic action of the alimentary canal.

Medical Uses.—Capsicum is of use by enabling feeble stomachs to digest food, as is shown by its efficacy in atonic *dyspepsia*. Freely taken, it is said to cure *hemorrhoids*, as black pepper and still other stimulants are known to do. It perhaps sometimes cures *intermittent fever*, and in obstinate cases is a good stimulant to conjoin with quinia. Chéron attributes to capsicum the power of controlling *menorrhagia*. In common with other agents of the same nature it tends to prevent or to relieve *sea-sickness*. In *delirium tremens* it is beneficial by enabling the patient to retain and digest food; indeed, we have seldom in this disease found it necessary to employ other internal remedies than a strong soup well seasoned with red pepper. As a local stimulant it is particularly efficient in *tonsillitis*. The simple form may sometimes be arrested in its first stage by a capsicum gargle; and in the sore throat of *scarlet fever* and in *diphtheria* no application is so efficient as a strong gargle or wash made with this substance.

The *dose* of powdered capsicum is from 5 to 10 grains (Gm. 0.30–0.60). An infusion is made by adding 40 grains (Gm. 2.50) of capsicum to half a pint of boiling water; of this a tablespoonful may be given at a dose. An infusion used with remarkable success in an epidemic of *angina maligna* (diphtheria?) is thus described: Take 2 tablespoonfuls of red pepper and the same quantity of fine salt; beat them into a paste, and add half a pint of very sharp vinegar. Of this the dose for an adult is said to be a tablespoonful every hour. It is excessively acrimonious, but it is alleged to hasten the separation of the false membranes and sloughs from the fauces. A plaster made of Burgundy pitch (or the official capsicum plaster), with which powdered capsicum or its oleoresin has been incorporated, is a very efficient stimulant in cases of chronic *lumbago* and other forms of muscular *rheumatism*, *neuralgia*, etc. Analogous to this is an "extract of red pepper" mixed with resin plaster and spread upon paper. These preparations excite a sense of warmth in the skin, and redden but do not vesicate it.

CARBO ANIMALIS, U. S., Br.—ANIMAL CHARCOAL.

Carbo ossium, Ebur ustum, Spodium.—Boneblack, Ivory black, E.; *Charbon animal, Noir d'os, Fr.; Thierkohle, Knochenkohle, Beinschwarz, G.*

Charcoal prepared from bone.

Preparation.—Boneblack of commerce is obtained by roasting bones deprived of fat in iron cylinders until vapors cease to be given off, when charcoal is left intimately mixed with about ten times its weight of the inorganic constituents of bones, and containing a little nitrogen, probably as nitrogen carburet. The volatile products of this dry distillation are various gases, an ammoniacal aqueous liquid called *bone-spirit*, and a blackish-brown tar called *bone-oil*.

CARBO ANIMALIS PURIFICATUS, U. S., Br.—Purified animal charcoal, E.; *Charbon animal purifié, Fr.; Gereinigte Knochenkohle, G.*

Animal Charcoal, in No. 60 powder, 2 parts; Hydrochloric Acid 3 parts; Water a sufficient quantity. Pour the hydrochloric acid, previously mixed with 15 parts of water, upon the animal charcoal, and digest the mixture on a water-bath for 24 hours, occasionally stirring. Pour off the supernatant liquid and digest the undissolved portion with 15 parts of water for 2 hours. Transfer the mixture to a strainer, and when the liquid portion has run off wash the residue with water until the washings cease to be affected by test solution of nitrate of silver. Dry the product, heat it to dull redness in a closely-covered crucible, and when cool keep it in well-stopped bottles.—U. S.

The process of the British Pharmacopœia is very similar to that given above, 16 ounces of boneblack, 10 fluid-ounces of hydrochloric acid, and 20 fluidounces of water being used.

Carbo carnis, or meat charcoal, is prepared by cutting 3 parts of veal, freed from fat, in small pieces, mixing it with 1 part of small bones, and roasting in a covered vessel until inflammable vapors cease to escape; the residue when cold is powdered.

Properties.—Boneblack, like purified animal charcoal, is a dull black, rather dense, inodorous, and nearly tasteless mass, which for uses in the arts is either granulated or powdered. It is entirely insoluble in all simple solvents; the purified animal charcoal also in hydrochloric acid, which dissolves a portion of the boneblack. The compounds removed in its purification are the inorganic constituents of the bones, and consist mainly of calcium phosphate, with some calcium carbonate and magnesium compounds. When ignited with free access of air, boneblack leaves a white ash, amounting to at least 86 per cent. of the original weight, which should be completely soluble in hydrochloric acid with the aid of heat. It has the remarkable property of removing organic coloring matters from their neutral or somewhat acid solutions, and is employed for that purpose in the refining of sugar and in many chemical operations, for many of which its previous purification is requisite to avoid contamination with earthy matters which would be dissolved by the organic acids.

Tincture of litmus diluted with twenty times its bulk of water, agitated with purified animal charcoal and thrown upon the filter, passes through colorless.—Br. When ignited at a high temperature with a little red oxide of mercury and free access of air, purified animal charcoal leaves at most only a trace of residue.—U. S., Br. If 1 part of it be digested with 2 parts of hydrochloric acid and 6 parts of water, no effervescence should take place (absence of carbonates), and the filtrate should not yield a precipitate on being supersaturated with ammonia (absence of earthy phosphates); boneblack yields a voluminous white or whitish precipitate. The clear ammoniacal liquid or filtrate should not be precipitated by solution of barium chloride or test mixture of magnesium (absence of alkali sulphate and phosphate), and on being evaporated to dryness and ignited should leave no fixed residue (absence of potassium and sodium salts).

Purified animal charcoal removes from their aqueous solutions tannin, alkaloids, bitter principles, basic lead and other metallic salts, iodine, lime, etc.—a property which it shares more or less with boneblack, and which was first observed by Figuier (1810). This property is due to the finely-divided state of the carbon and the surface attraction resulting therefrom, and may be imparted to wood charcoal if, previous to charring, the vegetable substances are intimately mixed with flint, lime, or other earthy matters; a mixture of 10 parts of pipe-clay, 50 parts of finely-powdered coal, and 2 of tar yields, after carbonization, a charcoal possessing excellent decolorizing properties, depending in part upon the presence of alumina. By reheating purified animal charcoal with potassium carbonate its decolorizing power, which was impaired by the treatment with acid, is greatly increased, and similar active charcoals are obtained from blood, horn, leather, etc. by mix-

ing them with the salt mentioned, carbonizing the mixtures, and exhausting the residues with water.

The value of animal charcoal as a decolorizer is best ascertained by treating known weights of it with diluted solutions of indigo or litmus, and ascertaining the bulk which may be completely decolorized by slow percolation. Corenwinder (1853) proposed treatment of the charcoal with diluted solutions of lime and sugar, and determining by titration the amount of lime remaining in solution. The decolorizing property, however, does not appear to be strictly proportional to the lime- or salt-absorbing power of animal charcoal. When the decolorizing power of the charcoal has been exhausted it cannot be restored by heating to redness, because a dense charcoal, resulting from the absorbed substances, will then be deposited in the pores; but if allowed to ferment this substance will be destroyed, and by washing the charcoal with water, drying, and igniting it becomes again a good decolorizer. Pelouze (1854) proposed to effect the revivification of spent animal charcoal by treating it with caustic alkalies or alkaline carbonates; according to Renner (1862), the process is a tedious one. Placing the decolorizing power of bone-black = 1, Bussy ascertained that of purified animal charcoal to be = 1.6; purified animal charcoal ignited with potassium carbonate = 20; blood ignited with potassium (or calcium) carbonate = 20; glue ignited with potassium carbonate = 15.5.

Composition.—Animal charcoal consists of amorphous carbon intimately mixed with the inorganic compounds of bone (see Os), chiefly phosphate and carbonate of calcium, which are partly or wholly removed in purification with hydrochloric acid.

Pharmaceutical Uses.—The chief use of animal charcoal is for decolorizing the aqueous or alcoholic solutions of organic principles; the *purified* animal charcoal should alone be employed.

CARBO LIGNI, U. S., Br.—CHARCOAL.

Carbo ligni pulveratus, P. G.; *Carbo præparatus*, *Carbo e ligno*, *Carbo vegetabilis*.—Wood charcoal, E.; *Charbon végétal*, Fr.; *Holzkohle*, *Präparirte Kohle*, G.

Charcoal prepared from soft wood.

Preparation.—Wood heated to about 300° C. (572° F.) leaves charcoal as a residue. On a large scale this is effected in iron cylinders (see ACIDUM ACETICUM PYROLIGNOSUM), in closed chambers of brick, or by the method of pile-burning, in which the heat developed by the combustion of a portion of the wood effects the charring of the rest. Two, and sometimes three, stacks of billets of wood of even length are piled up around some stakes driven into the ground until a flattish cone of from 30 to 70 feet in diameter has been formed, which is covered by sod and earth, openings being left near the base for the escape of the water which is at first expelled. After the heap has been kindled in the centre the top opening is closed, and when the wood has become perfectly dry the open space at the base is likewise closed and the pile left to smoulder for several weeks. The charcoal is finally withdrawn and extinguished by water, dry sand, or charcoal-dust. The yield varies with the kind and dryness of the wood. Karsten found that a wood which lost at 100° C. 57 per cent. and at 150° C. (302° F.) an additional 10 per cent. of its weight, would yield only 14 per cent. of charcoal, while the same wood dried yielded 25 per cent. The difference is explained by the formation of carburetted hydrogen on the passing of aqueous vapors over red-hot charcoal, and the same cause accounts for the smaller yield in the dry distillation of wood when the cylinders are rapidly heated, so that the wood near the iron is charred while the pieces in the centre still contain water.

Properties.—Charcoal has the shape and shows the texture of the wood from which it was obtained; it is black, odorless, tasteless, very porous and brittle, insoluble and infusible. Alcohol in which charcoal has been digested should not become colored, and on evaporation should leave no residue. When charcoal is heated in the air it is converted into carbonic oxide or dioxide, but it should not burn with flame (absence of organic compounds). Ordinary wood charcoal is usually incompletely carbonized, and requires to be again ignited in nearly-closed vessels until it ceases to give off inflammable vapors, and to be reduced to a uniform, fine, non-gritty, dull-black powder before it is adapted for medicinal use. Prepared by pile-burning, charcoal is considerably denser than when obtained in retorts; the latter kind is therefore preferable, particularly that made from soft wood, which is more porous than that obtained from hard wood. Charcoal made from young shoots of the willow, poplar, or linden is for these reasons most esteemed. It contains the inorganic constituents present in the wood, and these amount in well-prepared charcoal to about 1 per cent.

Like other porous bodies, wood charcoal possesses the property of absorbing gases; this was first observed (1777) by Fontana and by Scheele, and Lowitz (1785) discovered the clarifying and decolorizing property of wood charcoal, in consequence of which it was used in the refining of sugar until animal charcoal was found to be better adapted for this purpose. The volumes of gases absorbed by recently-ignited wood charcoal are not uniform, but vary with the nature of the gas and of the charcoal, as was shown by Morozzo (1783), the absorbing power being for oxygen 10, for carbonic acid 35, for sulphuretted hydrogen 55, and for ammonia about 100 volumes, to 1 of the charcoal. Considerable heat is generated thereby, as also by the oxidation of some of the gases by the absorbed oxygen, and may increase to spontaneous ignition; and the increase in weight of pile-burned charcoal may amount to from 10 to 15 per cent. by absorption of watery vapors. This property explains the uses of charcoal as a deodorizer, for which purpose it should be freshly burned or reheated to expel the gases condensed in its pores. Odorous principles are not only absorbed by it from the atmosphere, but likewise from solutions in water and weak alcohol; its employment for the removal of the fusel oil from spirits is well known. (See ALCOHOL.) It acts in a manner similar to animal charcoal in precipitating from their aqueous solutions metallic salts, or even the metals, most bitter principles, and coloring matters; but for the latter purpose is much inferior to the former.

Composition.—Wood charcoal is amorphous carbon mixed with the inorganic constituents of the wood from which it has been prepared. If insufficiently burned it is also contaminated with empyreumatic products resulting from the partial decomposition of the organic principles.

Pharmaceutical Uses.—Wood charcoal is an ingredient of certain dentifrices, and is employed in some chemical processes for its deoxidizing action, as in the preparation of sulphurous acid and in the reduction of bromates and iodates to bromides and iodides. It is used in making *Cataplasma carbonis*, Br.

CARBONEUM, Carbonium.—Carbon, *E.*; Carbone, *Fr.*; Kohlenstoff, *G.*—Symbol C. Atomicity quadrivalent or bivalent. Atomic weight 12.—Carbon is extensively diffused in nature: combined with oxygen as carbonic anhydride, CO₂, usually called carbonic acid gas, it exists to a small extent as a constant ingredient of the atmosphere; it is found in the mineral kingdom in the free state as well as in various combinations, most notably as carbonates; and it is invariably present in all organized beings and organic compounds, which, when heated with a limited access of air, usually become black from carbonization—*i. e.* the separation of carbon.

Carbon exists in the following three allotropic modifications:

1. **DIAMOND** is found chiefly in India near Goleonda, Borneo, Southern Africa, and Brazil, and is in colorless and variously colored octahedrons of 3.5 to 3.6 specific gravity. It is a non-conductor of electricity and the hardest substance known. Lavoisier proved it to be pure carbon; when burned it usually leaves between 0.05 and 0.2 per cent. ash; amorphous diamond, which is used for polishing the crystalline, may leave up to 2 per cent. The value of crude diamonds exported in 1881 from the Cape of Good Hope is estimated to exceed £4,500,000.

2. **GRAPHITE**, Plumbago or black lead (Plombagine, Crayon noir, *Fr.*; Wasserblei, Reissblei, *G.*) has been found in many countries, crystallizes in hexagonal plates varying in specific gravity between 1.8 and 2.5, is of a black-gray color, fatty to the touch, quite soft, and a good conductor of electricity, and leaves between 0.2 and 5 per cent., occasionally even as much as 46 per cent., of ash.

3. **AMORPHOUS CARBON** exists in nature as *coal*, of which there are three principal varieties—namely, *lignite*, *bituminous coal*, and *anthracite* (*lithanthrax*)—which contain respectively about 66, 80, and 90 per cent. of carbon, partly in the form of organic compounds. Artificially prepared, it constitutes *wood charcoal*, *animal charcoal*, *coke*, and *lampblack*, the latter being obtained by the incomplete combustion of resinous matters; after it has been heated in covered vessels to expel the volatile organic compounds it constitutes a nearly pure carbon.

Coke is the residue left from the dry distillation of coal, and consists of amorphous carbon contaminated with the mineral constituents of the coal.

When burned with an insufficient supply of oxygen, carbon is converted into *carbonic oxide*, CO; with a full supply of air it yields *carbonic acid*, CO₂. The chemistry of carbon in its various combinations constitutes what is known as *organic chemistry*.

Physiological Action.—Charcoal in the stomach absorbs more or less of the gases and liquids contained in that organ. Unlike alcohol, salt, and some other substances, it does not retard—but, on the contrary, hastens—the decomposition of organic matter, while it renders latent the gases evolved during the process. Its power of absorption depends upon its remarkable porosity, and, as charcoal is indestructible, this property is lasting, and can be revived in its original power by heating the charcoal anew. It seems probable that the minute subdivision and insolubility of powdered charcoal, and consequently its great superficial extent, enables it to present a very large surface of the

decomposing material to the oxygen of the air, and thus to ensure its destruction. In point of fact, the most fetid gases disengaged by putrefaction are among those which, on the one hand, are most abundantly absorbed by charcoal—viz. ammonia, sulphuretted hydrogen, and sulphurous acid—and, on the other hand, oxygen, which combines with the other substances and generates new and inodorous compounds. That a portion of this action is owing to the minute subdivision of the charcoal is shown by the analogous effects of dry earth, sand, and gravel upon decomposing organic matters; and whether the action is due to any other cause is more than doubtful. It is not determined absolutely whether charcoal derived from ivory or bone or box-wood, or that which is prepared from poplar or other light porous wood, is the more efficient, but it is certain that charcoal of any kind is most active when freshly made.

Medical Uses.—For all forms of *flatulence* charcoal is one of the most certain remedies, and at the same time for those other *dyspeptic* phenomena which sometimes attend it, particularly nausea, fetid breath, foul taste in the mouth, constipation, palpitation of the heart, etc. It is remarkable that charcoal does not tend to produce *constipation*, but rather to moderate it when it exists. The cases in which it is said to accumulate in the bowels and obstruct them are not well authenticated. Its power of relieving flatulence is not confined to that of the stomach and small intestine; it has proved efficient when the colon was alone distended and a stricture existed near the sigmoid flexure. It has seemed to be a remedy for intestinal *worms* in some cases of intestinal indigestion with colic, flatulence, and irregular stools. Jules Guérin, Maurel, and others (*Bull. de therap.*, xeviii. 279; xcix. 274) found finely-powdered charcoal a very efficient remedy for choleric form *diarrhœa* both in adults and children. It was administered with milk diluted with water and sweetened. In epidemic *dysentery* it has proved very serviceable when administered by the stomach and also by the rectum, allaying the tormina and tenesmus and correcting the fetor of the stools, while it lessened their frequency and rendered them more feculent. It has been recommended for lessening *tympanites* in typhoid fever, but its administration does not produce this result, and has occasioned intestinal hæmorrhage. As an application to *gangrenous* and foul *ulcers*, incorporated largely in a poultice made with flaxseed, bread-crumbs, or yeast, it is very efficient in correcting the smell and hastening a separation of the dead tissue. As an ingredient of dentifrices for cleansing the *teeth* and purifying the breath the use of charcoal is familiar. Its deodorizing power has caused it to be employed in the arts and for sanitary purposes, as for preventing the generation of *putrid gases* in graves, vaults, sewers, privies, and innumerable analogous places, and notably for the filtration of *foul drinking-water*, which it not only deprives of its smell, but also of its organic constituents, and renders it pure and clear. These two properties are extensively employed in the arts.

The *dose* of charcoal is 1 or more teaspoonfuls. It should be as freshly prepared as possible. If intended to correct digestive fermentation, it should be taken directly after meals, and is best administered in water, the portion adhering to the mouth being washed down by a mouthful of water alone. It has been prepared and given in gelatin capsules. This method ensures a more active preparation than one which has been exposed to the air.

CARBONEI BISULPHIDUM.—BISULPHIDE OF CARBON.

Carboneum sulfuratum, P. G.; *Alcohol sulfuris*, *Carbonii bisulphidum*.—*Carbon disulphide*, E.; *Sulfure de carbon*, Fr.; *Schwefelkohlenstoff*, *Schwefelalkohol*, G.

Formula CS₂. Molecular weight 76.

Origin.—Scheele (1777) noticed the production of a very fetid gas on heating a mixture of sulphur and charcoal, but Lampadius (1796) by accident first obtained the compound in a liquid state. Clément and Désormes (1802) elaborated a process for its preparation, and stated it to be a compound of carbon and sulphur; its exact composition, however, was first proven by Vauquelin (1811) and by Berzelius (1812).

Preparation.—Bisulphide of carbon is made on the large scale by heating fragments of charcoal or coke to redness and occasionally dropping through a tube, to the bottom of the retort, pieces of sulphur, which is vaporized and unites with the red-hot charcoal. The condensed liquid contains sulphur in solution, from which it is freed by distillation in a water-bath, and the compounds having a disagreeable odor are removed by prolonged agitation with milk of lime, litharge, certain metals, powdered corrosive sublimate, or copper sulphate, decanting, adding about 2 per cent. of a bland fixed oil or beeswax, and rectifying in a water-bath. E. Allary (1881) uses for the same purpose water and potas-

sium permanganate, the latter added in small quantities, until after agitation the liquid retains its violet color; redistillation is not necessary. Bisulphide of carbon should be kept in well-stopped bottles in a cool place, remote from lights or fire.

Properties.—Thus obtained it is a very mobile colorless liquid having a high refracting power, and when quite pure a rather agreeable ethereal odor and a pungent aromatic and cooling taste; but often it is of a more or less fetid odor from the presence of other volatile compounds. It has the specific gravity 1.290 at 0° C. (32° F.) and 1.269 at 15° C. (59° F.) (1.272 *U. S.*). It boils at 46° C. (114.8° F.) (Buff), or at 47° C. (116.6° F.) (Kopp). It evaporates rapidly at the ordinary temperature, and on passing a rapid current of dry air over its surface partly congeals. It is very inflammable—more so than ether—and burns with a blue flame, yielding sulphur dioxide and carbon dioxide or monoxide. It requires about 1000 parts of water for solution, is soluble in almost all proportions of absolute alcohol, ether, chloroform, and fixed and volatile oils, and in 1½ to 2 parts of official alcohol. It dissolves freely phosphorus, sulphur, bromine, iodine, fats, volatile oils, caoutchouc, and other compounds, and unites with some of the sulphur bases, forming *sulphurcarbonates*, which correspond to the carbonates containing sulphur in place of oxygen. Dissolved in alcohol and heated in the presence of ammonia, *sulphocyanide* (*sulphocyanate*) of ammonium and hydrosulphuric acid are produced; $\text{CS}_2 + 2\text{NH}_3$ yields $\text{NH}_4\text{CNS} + \text{H}_2\text{S}$.

Tests.—Carbon bisulphide should not change the color of moistened litmus-paper (absence of sulphurous acid), and when agitated with solution of lead acetate should not produce a brown or black color (absence of hydrosulphuric acid). A portion evaporated spontaneously in a glass or porcelain vessel should leave no solid residue (absence of sulphur).

Uses.—In the arts it is largely employed for the extraction of fats and in the vulcanization of caoutchouc, and has been proposed as a solvent for obtaining the delicate perfumes of flowers.

SULPHOCARBONATE OF POTASSIUM, K_2CS_3 , is prepared by agitating potassium monosulphide, K_2S , with carbon bisulphide, and evaporating at about 30° C. (86° F.). It forms yellow deliquescent prisms, which are sparingly soluble in alcohol, have a peppery and sulphurous taste, and above 60° C. (140° F.) are converted into the red-brown anhydrous salt. A solution containing also potassium carbonate, but sufficiently pure for destroying the *phythovora* and other insects, is made by agitating potassa solution with carbon bisulphide as long as the latter is dissolved; and if alcohol be present *potassium xanthogenate*, $\text{K}(\text{C}_2\text{H}_5)\text{CS}_2\text{O}$, is also formed. Both salts are slowly decomposed in the soil, with the liberation of carbon bisulphide.

History and Physiological Action.—Bisulphide of carbon was described in 1826 by Lampadius, who discovered the compound in 1796. He noted its rubefacient and also its refrigerant action upon the skin, and recommended its vapor in syncope, and the use of liniments containing it for frost-bite, rheumatism, and local paralyses, as well as its internal administration. Mansfield and others employed it in gouty and rheumatic disorders and for quickening uterine contractions. Pellingahr wrote of it as a cardiac stimulant, diuretic, and emmenagogue, but found it useless in gout and rheumatism (Richter, *Ausführlich. Arzneimittel.*, iii. 464; Supl. Bd., p. 457). Tiedemann described its effects upon animals, and Kaaf upon himself, confirming the observations of Pellingahr (Strumpf, *Arzneim.*, ii. 533). Krimer applied it to produce cold by evaporation in the reduction of strangulated herniæ. Turnbull employed a sponge saturated with the liquid and contained in a wide-mouthed bottle, which he applied over indurated lymphatic glands. Page of Boston applied its vapor to the relief of local pains; and Schiel of St. Louis used it in a liquid form with alcohol in similar cases, and especially in neuralgia (*U. S. Dispensatory*, 1830). A similar application of it was made by Nessley of Ohio in 1872. Michaelson applied it to burns on cotton wadding. It appears to have been first used as a general anæsthetic by Harold Tanlow in 1848 (Guibert, *Nouveaux médicaments*, p. 604), and soon afterward it was tried on man by Dr. Simpson of Edinburgh, and by Snow on mice (Pereira, *Mater. Med.*, 1848; Amer. ed., i. 377). Simpson described it as a very rapid and powerful anæsthetic, but in several instances it produced depressing and disagreeable visions, and was followed by headache, giddiness, and obstinate vomiting. It rendered the pulse very frequent. Its anæsthetic effect also was very transient; and another objection to its use was found in its very unpleasant odor, which was compared to that of putrid cabbage. When pure it loses this peculiarity. Applied topically, it blunts the sensibility of the skin. Its deleterious effects have been observed in manufactories where it was employed as a solvent for caoutchouc. They have been enumerated by several physicians (Delpech, Heurtaux), and consist primarily of a morbid excitement

of body and mind, followed by mental feebleness, confusion of ideas, and even delirium, with sleeplessness, faintness, vertigo, headache, nervous pains, muscular cramps, debility, anæsthesia, atrophy, amaurosis, and sexual impotence. Anorexia, nausea, vomiting, constipation or diarrhoea, palpitation, and shortness of breath are also observed. Taken internally in the dose of 2 or 3 drops, it burns the mouth and throat, and occasions nausea, vomiting, flatulence, and dysuria. It does not appear to be decomposed in the blood.

Medical Uses.—This anæsthetic has been found useful for producing insensibility of the skin in limited surgical operations, such as *opening abscesses, the evulsion of nails*, etc. It has also been applied locally for the relief of *headache, neuralgia*, and *toothache*. It has been found to relieve the neuralgic pains of *locomotor ataxia* when applied along the spine; and recently Sanders (*Med. News*, xl. 371; xlii. 201) has stated that he found it very efficient as a topical remedy in pure *neuralgia*, especially of the occipital, cervical, intercostal, and sciatic nerves. In other words, its action, like that of chloroform, is counter-irritant and anæsthetic. It has been made use of, but not very successfully, to lessen the swelling of enlarged *lymphatic glands*, of *goitre*, and of *lupoid* and *syphilitic* growths. For the latter purposes it may be applied in an ointment containing 1 part of the preparation to from 5 to 10 of lard. For producing local anæsthesia it may be employed as an atomized vapor. It is alleged to be a very efficient application for indolent *ulcers* when slightly brushed over their surface, which should then be dusted with sub-carbonate of bismuth and supported by a bandage. The liquid causes severe pain for a few moments. Tincture of iodine is said to correct the objectionable odor of this preparation when mixed with it in the proportion of one-fourth. The mixture may also be scented with mint, bergamot, etc. Bisulphide of carbon may be administered internally in doses of from 2 to 6 or more drops. It may be taken in an alcoholic liquor, in mucilage, or in milk.

CARBONEI TETRACHLORIDUM.—TETRACHLORIDE OF CARBON.

Carbonii tetrachloridum, Carboneum chloratum.—Chlorocarbon, Tetrachlor-methane. E.; *Bichlorure de carbone, Formène perchloré*, Fr.; *Chlorkohlenstoff*, G.

Formula CCl_4 . Molecular weight 153.6.

Preparation.—Chlorocarbon was discovered by Regnault in 1839, and is produced by the action, in sunshine, of chlorine upon marsh-gas, CH_4 , or upon chloroform, CHCl_3 , hydrochloric acid being also formed in both cases. It is best prepared by passing well-dried chlorine gas through bisulphide of carbon, and afterward through a porcelain tube wrapped in sheet copper and filled with fragments of porcelain maintained at a red heat, whereby tetrachloride of carbon and chloride of sulphur are produced; $\text{CS}_2 + 3\text{Cl}_2$ yields $\text{CCl}_4 + \text{S}_2\text{Cl}_2$. The vapors are condensed by the aid of ice or a refrigerating mixture, and the liquid thus obtained is slowly added to an excess of potassa solution or milk of lime, whereby the chloride of sulphur is decomposed and dissolved. The chlorocarbon separates at the bottom and is purified by distillation.

Properties.—It is a colorless, thin, oily liquid of an agreeable aromatic odor, insoluble in water, soluble in alcohol and ether, and not decomposed by contact with aqueous solution of potassa, which, however, will remove any bisulphide of carbon that may be present. Chlorocarbon has the spec. grav. 1.599, and boils at 77° (170.6° F.). Geuther (1858) observed that by the action of nascent hydrogen it is gradually converted into hydrochloric acid and chloroform or dichlor-methane, CH_2Cl_2 , according to the temperature at which the reaction takes place.

It is regarded as a chlorinated derivative of marsh-gas (see METHYLENI BICHLORIDUM); according to its elementary composition it is tetrachloride of carbon, or, according to the old notation, *bichloride of carbon*, CCl_2 or C_2Cl_4 , which name is still occasionally used.

Allied Compound.—CARBON TRICHLORIDE, HEXCHLORETHANE, C_2Cl_6 . Mol. weight 236.4.—It is prepared by passing, in sunshine, dry chlorine gas into ethyl chloride or ethylene chloride (see page 132) until the liquid congeals, when the mass is recrystallized from alcohol. Carbon trichloride forms colorless or white rhombic prisms, is brittle and easily pulverizable, has an aromatic camphoraceous odor, and is nearly tasteless. Its specific gravity is about 2.0. It is insoluble in water, freely soluble in alcohol, ether, fats, and volatile oils, burns in the presence of alcohol with a red flame, melts at 160° C. (320° F.), boils at 182° C. (359.6° F.), subliming in crystals, and volatilizes slowly at ordinary temperatures.

Physiological Action and Medical Uses.—Experiments on animals by Laffont and others show that this preparation produces anæsthesia, preceded by excitement, with tonic and clonic convulsions, great debility of the heart, and vascular tension. It causes

death by arresting the action of the lungs and distending the right side of the heart with blood. From 10 to 15 Gm. are required to induce anæsthesia in dogs. When inhaled by man it produces a sense of coolness in the fauces and of general warmth, followed promptly by anæsthesia and a complete return of consciousness. It has been used with success in relieving *neuralgia* and various local pains, including *dysmenorrhœa* and the throes of *parturition*. As its primary, or at least proximate, action is upon the heart, and as several deaths are laid to its charge, this preparation ought never to be employed internally.

CARDAMINE.—CUCKOO-FLOWER.

Herba nasturtii pratensis.—*Cresson des prés*, Fr.; *Wiesenkresse*, *Kukukskraut*, G.

Cardamine pratensis, *Linné*.

Nat. Ord.—Cruciferae, Siliquosae.

Origin.—This perennial plant grows in wet meadows and boggy places, and is a native of Europe, Northern Asia, and North America, but is rather scarce in the United States south to New Jersey and westward to Wisconsin.

Description.—The ascending stem is about a foot (30 Cm.) high and nearly smooth. The leaves are pinnate, with seven to thirteen leaflets; those of the lower leaves are on short stalks, roundish, entire, or somewhat toothed, the terminal one largest and nearly reniform; those of the upper leaves are linear and mostly entire. The flowers are showy, white, or rose-colored, and the pods linear, flattened, and with veinless valves. The fresh plant has a pungent and bitterish taste.

Constituents.—According to Lepage (1846), the seeds contain myrosin, but no myronic acid. Winckler found in the herb of *Cardamine amara* an acid containing nitrogen and sulphur and yielding with myrosin a volatile oil resembling that of mustard.

Allied Plants.—The following Cruciferae (see also ARMORACIA, COCHLEARIA, NASTURTIIUM, and SINAPIS) have sensible properties similar to those of the preceding plant, and have been occasionally used for similar purposes:

CARDAMINE HIRSUTA, *Linné*.—Small bitter-cress, common in Europe and North America; resembles the preceding, but is smaller: has small white flowers and slender, ascending pods.

CARD. AMARA, *Linné*.—Bitter-cress, indigenous to Europe, has pinnate leaves, with seven or nine roundish-ovate, stalked leaflets, showy white flowers, and purplish-blue anthers. It is less pungent and more bitter.

BARBAREA VULGARIS, *R. Brown*.—Wintercress, Yellow scurvy-grass, *E.*; *Herbe de Sainte-Barbe*, *Fr.*; *Winterkresse*, *G.*—This biennial herb, like the very similar *Bar. præcox*, *R. Brown*, is sometimes cultivated for salad, and is common in Europe and North America; it has lyrate leaves, with large round or ovate sometimes heart-shaped terminal lobes, the upper leaves obovate, toothed; flowers numerous, yellow; pods somewhat spreading.

DENTARIA.—Pepper-root, Toothwort, *E.*; *Dentaire*, *Fr.*; *Zahnwurz*, *G.*—The rhizomes have a very pungent taste, and are cylindrical in *D. diphylla*, *Linné* (North America), and *D. bulbifera*, *Linné* (Europe), but composed of several tubers in *D. enneaphylla*, *Linné* (Europe), and in the North American species, *D. maxima*, *Nuttall*, *D. heterophylla*, *Nuttall*, *D. laciniata*, *Muhlenberg*, and *D. multifida*, *Muhlenberg*.

SISYMBRIUM (ERYSIMUM, *Linné*) ALLIARIA, *Scopoli*, s. *Alliaria officinalis*, *Andrews*.—Hedge-garlic, *E.*; *Alliaire commune*, *Fr.*; *Knoblauchkraut*, *G.*—Pless (1846) obtained from the herb and seeds a mixture of mustard and garlic oil, to which the alliaceous odor is due; they contain also a bitter principle.

SISYMBRIUM (ERYSIMUM, *Linné*) OFFICINALE, *Scopoli*.—Hedge-mustard, *E.*; *Herbe aux chantres*, *Tortelle*, *Fr.*; *Wilder Senf*, *Hederich*, *G.*—An annual herb with runcinate leaves, small yellow flowers in terminal spicate racemes, and linear appressed pods. The seeds have a sharp mustard-like taste, and yield oil of mustard; the herb is milder.

Medical Action and Uses.—*Cardamine* contains an acrid principle when fresh, which causes it to resemble water-cresses and scurvy-grass in taste. Like them, it is sometimes eaten as a salad, and has popular reputation as a “purifier of the blood.” The flowers were once claimed to display a certain efficacy in gout, and even in chorea, hysteria, and epilepsy, and to possess expectorant and diuretic virtues. Its medicinal use is now obsolete, even in Europe. The allied plants enumerated have analogous virtues.

CARDAMOMUM, U. S., Br.—CARDAMOM.

Fructus (Semen) Cardamomi (minoris), P. G.; *Cardamomum minus*, *Cardamomum malabaricum*.—*Malabar cardamoms*, E.; *Cardamomes*, Fr.; *Cardamomen*, *Kleine Kardamomen*, G.

The fruit of *Elettaria Cardamomum*, *Maton*, s. *Alpinia* (*Amomum*, *White*, *Matonia*, *Smith*, *Renealmia*, *Roscoe*) *Cardamomum*, *Roxburgh*. *Bentley and Trimen. Med. Plants*, 267.

Nat. Ord.—Zingiberacæ.

Origin.—This perennial plant is indigenous to Hindostan, more particularly to the mountainous region of the Malabar coast, where it is also extensively cultivated in clearings made in the forests, so that the plants will enjoy sufficient shade, or in the betel-nut plantations, as in Mysore. It grows to the height of 6 to 10 feet (1.8 to 3 M.) from a thick horizontal rhizome, has lanceolate leaves which are 1 to 2 feet (.3 to .6 M.) long, and almost sessile upon the long hairy sheaths, and produces three or four nearly horizontal scapes which bear several short racemes of greenish-white flowers. It flowers during the rainy season, and the inferior capsules are collected from and after October, before they are quite ripe, to avoid their splitting, and dried by artificial heat. The drug is exported in chests from Bombay, Madras, and other East Indian ports. 29,000 pounds of cardamom were imported into the United States in 1876, and 65,000 pounds in 1880.

Description.—Cardamom-fruits vary in length from $\frac{2}{3}$ to $\frac{4}{5}$ inch (1 to 2 Cm.), and are commercially divided into *shorts* and *short-longs* or *mediums* and *longs*. They are ovoid or oblong, obtusely triangular, rounded at base, beaked above, of a pale-buff color, longitudinally striate, and three-celled. The capsular integuments are thin, leathery, the three cell-partitions starting from the centre of the valves. The seeds are attached to a central placenta in two rows, brown, slightly glossy, about $\frac{1}{8}$ inch (5 Mm.) long and $\frac{1}{8}$ inch (3 Mm.) broad, angular, transversely rugose, with a depressed hilum and a channelled raphe on one side, and contain a club-shaped embryo, the radicle projecting toward the hilum, and the upper part completely surrounded by the horny endosperm, and this by a thicker saccate layer of granular perisperm. Each seed is enclosed in a thin membranous nearly colorless arillus. The integuments are nearly inodorous and tasteless; the seeds have an agreeable odor and a warm aromatic and pungent taste. The seed-coat consists of three distinct layers, each one formed of a single thickness of cells, those of the outer layer being brownish, rather thick-walled, and upon transverse section square in outline and small; those of the second layer, much larger, thin-walled, square; and those of the inner layer, radially elongated, dark-brown, and with a small cavity near the outer end. The outer albumen contains minute starch-granules and crystalloid proteids; the inner albumen and embryo are filled chiefly with fixed oil and mucilage; the volatile oil is mostly contained in the large thin-walled cells of the testa.

Good cardamoms should be full and plump, and yield 75 per cent. of their weight in seeds. Malabar and Aleppo cardamoms are usually ovoid and have a short beak; Madras cardamoms are more oblong and acuminate.

FIG. 50.

Malabar Cardamom: a, short; b, medium; c, long.

FIG. 51.

Cardamom-seed; transverse and longitudinal section; magnified 5 diameters.

FIG. 52.

Ceylon Cardamom: a, capsules; b, transverse section of capsule; c, seeds; d, section of seed with embryo; magnified.

Other Varieties of cardamoms are used in the East Indian islands and China, but are rarely met with in our commerce. The *Ceylon* or *long cardamoms* are occasionally seen in commerce; they are obtained from *Elettaria major*, *Smith*, which is now usually regarded as a variety of the

official plant and is indigenous to Ceylon. The fruit is about $1\frac{1}{2}$ inches (4 Cm.) long, lanceolate oblong, acutely triangular, with flat sides and a long, attenuated apex. It is usually of a darker color, and the seeds are less agreeable in odor and taste. The *round cardamoms* of Siam, Java, and other islands are the fruits of *Amomum cardamomum*, Linné, of the size of a cherry, globular or somewhat ovate in shape, the three sides convex; the taste of the seeds is more camphoraceous. The *Bengal cardamoms*, obtained from *Am. aromaticum*, Roxburgh, are an inch long, oblong or oval, rounded below, terminated by a short nipple, and near the apex provided with nine wings. Similar in appearance, but terminating above in a long beak-like calyx, is the *Nepal cardamom*, the origin of which is not known. The *large or winged Java cardamom* is the nearly globular capsule of *Am. maximum*, Roxburgh, about 1 inch (25 Mm.) long, obtusely triangular, each side provided with three or four firm, short membranaceous wings, which are best observed after soaking the fruit in water. The *round Chinese cardamoms*, which are rounded on the side, are probably produced by *Am. globosum*, Loureiro.

Constituents.—Trommsdorff (1834) obtained 4.8 per cent. volatile oil, 10.4 fixed oil, and smaller quantities of starch, malate (?) of potassium, gummy extractive, and coloring matter. The volatile oil has a spec. grav. of .93 to .94 and the odor and taste of the seeds, is colorless or yellowish, dextrogyre, and contains oxygen. Flückiger (1872) found nearly 11 per cent. of moisture and 15 per cent. of ash in the air-dry fruit, and in the ash 0.79 per cent. of manganese, which he also observed to be present in the leaves and fruits of other Zingiberaceæ.

Off. Prep.—*Extractum colocynthidis comp.*, *Pulvis aromaticus* (cinnam. comp.), *U. S.*, *Br.*; *Pulv. cretæ comp.*, *Br.*; *Tinct. cardamomi*, *Tinct. rhei dulcis*, *U. S.*; *Tinct. cardam. comp.*, *Tinct. gentianæ comp.*, *Tinct. rhei*, *Vinum aloes*, *U. S.*, *Br.* The British Pharmacopœia directs the seeds to be freed from the pericarps; the *U. S. Pharmacopœia* gives the same direction only for the second of the above preparations.

Medical Action and Uses.—Cardamom is a warm and agreeable carminative and stomachic. It may be added to tonic and stimulant preparations. An infusion made with 1 drachm (Gm. 4.00) of the bruised seeds in half a pint of boiling water may be given in doses of a wine-glassful. The official tinctures are more commonly employed.

CARDUUS BENEDICTUS.—BLESSED THISTLE.

Herba cardui benedicti, P. G.—*Chardon bénit*, Fr.; *Benedictendistel*, G.

The leaves and flowering tops of *Cnicus benedictus*, Gaertner, s. *Centaurea benedicta*, Linné.

Nat. Ord.—Compositæ, Cynaræ.

Description.—The “blessed thistle” is an annual woolly plant which is indigenous to Western Asia and South-eastern Europe, and has been naturalized in other parts of Europe, and sparingly so in the United States. It is about 18 inches (45 Cm.) high, has a reddish angular branching stem, and alternate, oblong or ovate-lanceolate, sinuately pinnatifid, and dentate leaves, each tooth bearing a soft spine. The lowest leaves are 8 inches (20 Cm.) or more long, and narrowed into an angular winged petiole; the upper ones are smaller, sessile, and somewhat decurrent. The flower-heads are terminal, ovate in shape, about $1\frac{1}{2}$ inches (31 Mm.) long, surrounded by large bracts, have the imbricate scales of the involucre prolonged into a yellowish spine, and contain numerous tubular yellow florets and terete many-ribbed akenes, which are crowned with ten short teeth and with a pappus consisting of ten long and ten alternate short bristles, the latter forming an inner row. The leaves and flowering tops are collected mostly from cultivated plants, and lose on drying about 75 per cent. The dry leaves have a grayish-green color. The taste is strongly bitter.

Constituents.—Analyzed by Morin, the widely-diffused constituents of herbs were found associated with a brown-yellow amorphous bitter principle. The latter was obtained pure by Nativelle (1839), and ascertained by Scribe (1842) to be present in allied plants. This *cnicin* is prepared like salicin, crystallizes in colorless needles, is very bitter, freely soluble in alcohol and wood-spirit, slightly so in cold water and ether, and dissolves in strong hydrochloric acid with a green, and in sulphuric acid with a red, color.

Pharmaceutical Uses.—The *Extractum cardui benedicti* of European pharmacopœias is made by exhausting the herb with hot water and evaporating.

Allied Plants.—*CENTAUREA CALCITRAPA*, Linné.—Star-thistle, *E.*: *Chardon étoilé*, Fr.; *Stern-distel*, G.—A European annual which is sparingly naturalized in some places of the United States near the coast. The pinnately-lobed leaves have the teeth prolonged into a thin spine, the involucre is spinous in the middle, the flowers are tubular and purple, and the akenes without pappus; the herb has a bitter taste.

CENTAUREA CYANUS, *Linné*.—Bluebottle, *E.*; Bluet, *Fr.*; Kornblume, *G.*—A European annual somewhat naturalized in North America, also cultivated. It has a globular involucre, with appressed fringed scales and bright blue-colored tubular florets, the marginal ones being largest. The nearly tasteless florets are employed in fumigating-powders.

Medical Action and Uses.—The “blessed thistle” was anciently, and even until quite recent times, held in high esteem as a remedy for all manner of diseases, including fevers and pulmonary, urinary, hepatic, and digestive disorders. It appears to have acted mainly as a bitter tonic, but in large doses it produced nausea, vomiting, and diarrhoea. Its active principle, *cnicin*, in the dose of 5 or 6 grains, causes a burning sensation and constriction in the pharynx and œsophagus, warmth in the stomach, and sometimes nausea, vomiting, colic, and diarrhoea. It has really no virtues differing materially from those of numerous other bitter tonics, and it most nearly resembles dandelion and colombo in its operation. It may be used in atonic *dyspepsia*—preferably, perhaps, in cases attended with hepatic congestion. The infusion is prepared with from $\frac{1}{2}$ ounce to 1 ounce (Gm. 15–30) of the herb to 8 fluidounces of water. The decoction is apt to nauseate. An extract has been employed in doses of from 5 to 15 grains. Star-thistle has virtues similar to those of “blessed thistle,” and blue-bottle (corn-flowers) florets are slightly astringent and have been used in collyria. Milk-thistle (*Carduus marianus*) is alleged to have arrested hæmoptysis (*Med. Record*, xxii. 625), but the evidence in its favor is inadequate. A writer in the *Edinburgh Med. Journal* (xxix. 284) identifies “Carmedik” with Kardenbenedikt, or “blessed thistle,” stating that the popular name is a corruption of the Dutch botanical title. It is an aromatic bitter, which possesses also a slight degree of astringency. (See *CARTHAMUS*.) *Cnicin* has been given in doses of from 5 to 10 grains as an antiperiodic.

CAROTA.—CARROT-FRUIT.

Fructus dauci s. carotæ.—Wild carrot-fruit, *E.*; Fruits de la carotte sauvage, *Fr.*; Möhrenfrucht, *G.*

The fruit of *Daucus Carota*, *Linné*. Woodville, t. 50; Bentley and Trimen, *Med. Plants*, 135.

Nat. Ord.—Umbelliferae, Orthospermæ.

Origin.—A biennial plant indigenous to Northern Asia and the greater part of Europe, and naturalized in this country, growing in dry fields and along roadsides, and cultivated to a considerable extent for its fleshy root. The furrowed stem is bristly, 1 to 3 feet (30 to 90 Cm.) high, branching; the leaves are bi- or tri-pinnatifid, the segments with lanceolate or linear incisions; the involucre consists of nine to twelve long pinnatifid leaves; the umbels are on long naked peduncles, at first level, finally concave; the flowers are white or whitish, the central one dark-purple, and commonly sterile, except in the first umbel, which, according to Meehan (1882), usually has a fertile central flower; the fruit is very hispid.

Description.—The fruit, which for medicinal purposes is collected from the wild plant, is about $\frac{1}{4}$ inch (3 Mm.) long, oval, dorsally compressed, and gray-brownish; each mericarp has five hispid filiform primary ribs, two of which are lateral, the remaining three upon the back; between these are four secondary ribs, two lateral and two upon the back, each beset with long spiny bristles, and covering one small oil-tube, two additional oil-tubes being upon the nearly flat face. The fruit has a slight aromatic odor and a pungent aromatic taste.

The root of the wild plant is thin, spindle-shaped, woody, white, of an aromatic odor and a pungent bitter taste; but cultivated it becomes conical, thick, fleshy, red or yellow, and acquires an agreeable odor and a pleasantly sweet taste.

Constituents.—The fruit contains a small quantity of oxygenated volatile oil; 324 grains of it were obtained from 100 pounds of the fruit. The root has been analyzed by Vauquelin, Wackenroder, and C. Schmidt, who found a little volatile oil (0.011 per cent.), uncrystallizable sugar, mannit, starch, pectin, albumen, fixed oil, malic acid, and a coloring principle named *carotin*, which exists in the root in red crystals, is tasteless; insoluble in water, slightly soluble in alcohol, ether, and chloroform, freely soluble in carbon bisulphide, benzol, and the fixed and volatile oils; its formula is $C_{40}H_{56}O$. Husemann (1860) found it to be accompanied in the root by *hydrocarotin*, $C_{48}H_{72}O$, which is colorless, tasteless, and obtained from boiling alcohol in silky crystals.

Action and Uses.—Carrot-fruit is diuretic and stimulant, and has long been used

for exciting the *menstrual* flow, for the cure of *dropsy*, and for the relief of *strangury*. Its medicinal properties appear to depend upon its volatile oil. The fresh root, reduced to a pulp by scraping or grating, forms an admirable poultice for indolent, gangrenous, and cancerous *ulcers*. The juice, used as a wash, is said to relieve *itching* in several *diseases of the skin*. The powdered fruit may be given in the *dose* of from 30 to 60 grains (Gm. 2-4). An ounce (Gm. 32) of the bruised fruit to a pint of hot water forms an infusion which may be taken within 24 hours.

CARTHAMUS.—SAFFLOWER.

Flores carthami.—*African or dyer's saffron, False (American) saffron*, E.; *Carthame*, Fr.; *Saflor*, G.

The florets of *Carthamus tinctorius*, Linné.

Nat. Ord.—Compositæ, Cynarææ.

Origin.—An annual plant which is indigenous to India and extensively cultivated there, in Eastern and Western Asia, Northern Africa, and Southern and Central Europe. It is about 2 feet (60 Cm.) high, with sessile or clasping spinulose leaves, and rather large ovate flower-heads terminating the branches. The florets are collected after the shedding of the pollen and are freed from the ovaries.

Description.—The florets of safflower are about $\frac{4}{5}$ inch (2 Cm.) long, tubular, with the limb divided into five nearly linear lobes; the tube of the anthers is about $\frac{1}{5}$ inch (5 Mm.) long, protrudes from the throat, and is surmounted by the long filiform yellow style. The florets are at first yellow, but become red, and after drying of a brown-red color. They have a faint, peculiar, rather disagreeable odor and an insipid bitterish taste.

Constituents.—The analysis of Dufour and Salvétat proved the presence of the usual constituents of plants, and in addition a yellow and a red coloring principle, the former being exhausted by water, after which the latter is obtained in solution by treatment with solution of sodium carbonate and precipitated by acids. Schlieper (1846) gives to this *carthamin* or *carthamic acid* the formula $C_{14}H_{16}O_7$. The value of safflower as a dyestuff depends upon the carthamin, which in the dry state is red-brown, has a green metallic lustre, is insoluble in ether, but dissolves in alcohol with a handsome purple color, the solution becoming yellow by heat. The alkaline solutions of carthamin decompose and decolorize rapidly.

Medical Action and Uses.—Safflower passes for being diaphoretic if administered in a warm infusion made with 2 drachms (Gm. 8) of the flowers and a pint of boiling water. It may be used to dissipate commencing *catarrh* and muscular *rheumatism* and to favor the efflorescence of *eruptive fevers*. In large doses it is said to be laxative. Its action and uses closely resemble those of chamomile. Carmedik, from the Cape of Good Hope, is said to be closely related to *Carthamus tinctorius*, but, unlike it, is extremely bitter as well as aromatic and astringent. It is used at the Cape as a stomachic bitter, infused in water or in brandy (*Edinb. Med. Jour.*, xxviii. 1073).

CARUM, U. S.—CARAWAY.

Carui fructus, Br.; *Fructus carvi*, P. G.—*Caraway-fruit (-seed)*, E.; *Carvi, Cumin des prés*, Fr.; *Kümmel*, G.

The fruit of *Carum Carvi* (Carvi), Linné. Woodville, *Med. Bot.*, plate 45; Bentley and Trimen, *Med. Plants*, 121.

Nat. Ord.—Umbelliferae, Orthospermææ.

Origin.—A biennial plant which is indigenous to the Western Himalayas and the Caucasus, and is found throughout Siberia and the greater portion of Europe, but is scarce in the southern part of that continent. It is extensively cultivated in Norway, Russia, Germany, Holland, England, Morocco, and also in the United States; the yield of fruit per acre is between 8 and 10 cwt. The hollow cylindrical stem is 1 to 3 feet (30 to 90 Cm.) high, branched; the leaves bi- and tri-pinnate, with the ultimate divisions linear; involucre filiform; involucrel none; umbels numerous; flowers small, white. The fruit is oblong, laterally compressed, splits when mature into the two mericarps, and finds its way into commerce from the countries named above. During the fiscal year 1866-67, 216,000 pounds of caraway were imported into the United States; at present about 1,000,000 pounds, including coriander, are annually imported.

Description.—The half-fruits are from $\frac{1}{4}$ to $\frac{1}{2}$ inch (3 to 4 Mm.) long, brown and smooth, somewhat curved, slightly narrowed at both ends, with a rounded stylopod above, five pale-colored filiform ridges, and between them on the back four grooves of a dark-brown color, which contain four large oil-tubes, two additional vittæ being on the flat face. *Mogador caraway* corresponds with this description, except that it is larger, attaining a length of fully $\frac{1}{2}$ of an inch (6 Mm.). Caraway has an agreeable aromatic odor and a sweetish and spicy taste.

FIG. 53.
Carum: fruit and longitudinal section, 3 diameters; transverse section, 8 diameters.

Constituents.—Besides volatile oil (see *OLEUM CARUI*), Trommsdorff found in caraway a green fixed oil, a little wax, resin, sugar, mucilage, and some tannin, the latter being particularly present in the green fruit. The medicinal properties are due to the volatile oil.

Off. Prep.—Aqua carui, Confectio opii, Conf. piperis. Pulv. opii comp., Br.; Tinct. cardamomi comp., U. S., Br.; Tinct. sennæ, Br.

Medical Action and Uses.—Anciently, caraway was held to be diuretic and carminative. It is used at present chiefly to expel wind and allay pain in the flatulent colic of infants. An infusion is prepared with 1 or 2 drachms (Gm. 4–8) of the bruised seeds and half a pint of boiling water, of which the dose is a teaspoonful for infants and a tablespoonful for adults.

CARYOPHYLLUS, U. S.—CLOVES.

Caryophyllum, Br.; *Caryophylli*, P. G.; *Caryophylli aromatici*.—*Girofle*, *Gérofle*, *Clous aromatiques*, Fr.; *Gewürznelken*, *Nägelein*, G.

The unexpanded flowers of *Eugenia caryophyllata*, Thunberg, s. *Eug. aromatica*, Willdenow, s. *Myrtus Caryophyllus*, Sprengel, s. *Caryophyllus aromaticus*, Linné. *Bot. Mag.*, vol. liv., plates 2749, 2750; Woodville, *Med. Bot.*, 193; Bentley and Trimen, *Med. Plants*, 112.

Nat. Ord.—Myrtaceæ.

Origin.—This handsome evergreen tree is supposed to have been indigenous only to the five small islands near the island of Jilolo, to which the name of Molucca or Clove Islands was formerly exclusively applied. The tree has been entirely destroyed there, but it is now cultivated in many of the islands of the Indian Ocean, in tropical Africa, Brazil, and the West Indies. It attains a height of 30 or 40 feet (9 or 12 M.), and is considerably branched, the branches forming an elegant pyramidal crown, and being terminated by cymes composed of fifteen to twenty-five flowers producing berry-like fruits.

Collection.—As soon as the buds change in color from green to red they are either picked by hand or detached from the trees by beating the branches with long bamboos, the buds being gathered upon cloths spread beneath the trees; they are afterward dried by exposure to the sun, whereby the color changes to brown. Between 1,000,000 and 1,500,000 pounds of cloves are annually consumed in the United States.

Description.—Cloves consist of a dark-brown, solid, nearly cylindrical calyx, somewhat tapering below, and above divided into four ovate lobes; these lobes clasp the four

FIG. 54.

Clove: a, natural size; b, longitudinal section, magnified.

lighter-colored arched and imbricate petals, which form a globular head and cover the numerous bent stamens. The ovary is contained in the upper part of the adherent calyx, is divided into two cells, each containing about twenty ovules, and is crowned by a quadrangular disk, in the centre of which the simple style is placed. Cloves are $\frac{1}{2}$ to $\frac{3}{4}$ inch (12 to 16 Mm.) long, and, as obtained from different localities, vary somewhat in the shade of their brown color; the large, plump, and deep-brown cloves, as obtained from the Moluccas, Zanzibar, etc., are preferred, the smaller, shrivelled, and light-colored varieties, such as are often exported from Cayenne and the West Indies, being considered inferior. Cloves have a somewhat fatty appearance, a strong and highly aromatic odor, and a very pungent, warm, and aromatic taste. A large number of oil-cells are observed in the petals and in the outer tissue of the calyx; the latter are placed in two or three irregular circles beneath the epidermis, and yield some of their oil upon pressure with the finger-nail. Cloves

partly deprived of their volatile oil are said to be occasionally used for adulteration; they are quite moist and usually without heads.

Other Parts.—CLOVE-STALKS (Griffe de girofle (*Fr.*); Nelkenstiele, Nelkenholz (*G.*); *Festuca caryophyllorum*, s. *Fusti*) are sometimes met with, and consist of the branching flower-stalks, about $\frac{1}{3}$ inch (2 Mm.) in thickness, which are of a light-brown color, and have a distinct though not strong odor and taste of cloves; they contain 4 to 5 per cent. of volatile oil, and are sometimes employed for adulterating powdered cloves and sometimes for distilling the volatile oil. The importation of clove-stalks into this country has increased from 15,128 pounds in 1877 to 184,464 pounds in 1880.

MOTHER CLOVES (*Mères de girofle*, *Clous matrices* (*Fr.*); Mutternelken (*G.*); *Anthophylli*) are the clove-fruits, generally collected before they are quite ripe; they are about 1 inch (25 Mm.) long, oval, crowned with the four-lobed calyx, have one or two seeds in each cell, and resemble cloves somewhat in appearance and properties, but are thicker, lighter, and weaker in odor.

FIG. 55.

Mother Clove.

Constituents.—Trommsdorff found in air-dried cloves 18 per cent. of volatile oil, 13 of tannin (which has not been further investigated), 13 of gum, 18 of water, 6 of tasteless resin, and 4 of extractive. Bonastre (1833) obtained from the watery distillate *eugenin*, in white pearly scales of a slight clove odor, having the composition $C_{10}H_{12}O_2$. Ostermeyer isolated a green wax, and Lodibert (1825) inodorous and tasteless silky needles, *caryophyllin*, of the composition $C_{10}H_{16}O$, which are deposited from the concentrated tincture of cloves; they are colored blood-red by cold sulphuric acid, and, according to Mylius (1873), yield with fuming nitric acid crystals of *caryophyllinic acid*, $C_{20}H_{32}O_6$. (For the composition of oil of cloves see *OLEUM CARYOPHYLLI*.)

Off. Prep.—*Infus. aurantii comp.*, *Infus. caryophylli*, *Mist. ferri arom.*, *Pulv. eretæ arom.*, *Br.*; *Tinctura lavandulæ comp.*, *Tinct. rhei arom.*, *U. S.*; *Vinum opii*, *U. S.*, *Br.*

Medical Action and Uses.—Cloves are general stimulants. They were formerly described as emmenagogue and aphrodisiac, and as suitable for expelling wind, allaying vomiting, and assisting digestion. They continue to be used for most of these purposes, but less as a medicine than as a condiment that promotes the digestion of fatty and crude food. Clove tea, made by infusing 2 or 3 drachms (Gm. 8–12) of bruised cloves in half a pint of boiling water, may be given in tablespoonful doses for the relief of *colic*. Powdered or bruised cloves wet with alcohol may be applied between cloths upon the epigastrium to allay *nausea* or *vomiting* and expel *flatus*, and upon the abdomen to relieve *colic*; but for these purposes the aromatic powder is preferable.

CASCARILLA, U. S.—CASCARILLA-BARK.

Cascarillæ cortex, *Br.*; *Cortex cascarillæ*, *P. G.*; *Cortex eluteriæ*, *Cortex thuris*.—*Sweet-wood-bark*, *E.*; *Cascarille*, *Ghuacille*, *Écorce éleuthérienne*, *Fr.*; *Cascarilla*, *Kuskarillrinde*, *G.*

The bark of *Croton Eluteria*, *Bennett*, s. *Clutia Eluteria*, *Linné*. *Jour. Proc. Lin. Soc.*; *Pharm. Jour.*, 2d ser. vol. iv. p. 150; *Woodville, Med. Bot.*, 223; *Bentley and Trimen, Med. Plants*, 238.

Nat. Ord.—*Euphorbiacæ*.

Origin.—This plant is a low or even a tree-like shrub with alternate, ovate-lanceolate, on the lower surface bronzed-silvery, leaves, and producing small white, monœcious, highly-odorous flowers in terminal and axillary spikes. The fruit is globular-ovate, scaly, silvery-gray, three-furrowed and three-celled, each cell containing a glossy orange-brown seed. The plant is indigenous to the Bahama Islands, where also *Croton Cascarilla*, *Bennett* (s. *Clutia Cascarilla*, *Linné*), and some other species of the same genus are met with, the barks of which may possibly sometimes be collected and sold as cascarilla. It is shipped in bags from Nassau, Bahamas, and has been known in Europe since the latter part of the seventeenth century.

Description.—It is in quills or channelled pieces 1 to 3 inches (25 to 75 Mm.) in length, about $\frac{1}{2}$ inch (12 Mm.) in diameter, and about $\frac{1}{12}$ inch (2 Mm.) thick, mostly, however, in small fragments. It is covered with a thin, grayish, easily detached corky layer, upon which are smaller or larger white patches of a minute lichen (*Verucaria albissima*, *Acharius*), the perithecia of which appear as black dots; the external layer, particularly of the older barks, is longitudinally and transversely fissured, presenting rectangular spaces with elevated edges, or is partly wanting. The inner bark is somewhat thicker, and has a brownish color and a smooth, brown-gray, inner surface. The bark breaks with a short somewhat resinous or horny fracture,

FIG. 56.

Cascarilla-bark: transverse section, magnified.

exhibiting in the outer layer some scattered oil- or resin-cells, and presenting a radially striate bast-layer in which but very few true bast-fibres are observed. It is rather fragrant when examined in bulk, but emits a strongly aromatic somewhat musk-like odor when burned; its taste is warm, aromatic, and very bitter.

Constituents.—Trommsdorff obtained from cascarilla 1.6 per cent. of volatile oil, 15.1 per cent. of resin, besides gum, potassium chloride, etc. The volatile oil consists of a hydrocarbon, $C_{19}H_{16}$ (Gladstone, 1872), and of an oxygenated portion. The resin is partly soluble in alkalis. Duval (1845), who isolated the bitter principle, *cascarillin*, in a crystalline state, announced also the presence of a little tannin, pectin, wax, fat, starch, and albumen. Cascarillin is obtained by concentrating the filtrate from the precipitate which is produced in an infusion by sugar of lead; it forms colorless needles or scales, is inodorous, bitter, fusible at $205^{\circ} C.$ ($401^{\circ} F.$), not precipitated by lead salts or tannin, freely soluble in ether and hot alcohol, sparingly soluble in cold alcohol and chloroform, and very sparingly in water; nitric acid converts it into a yellow resinous mass; sulphuric acid gives a red solution, from which water precipitates green floccules. C. and E. Mylius observed it (1873) in an extract separated in granules, and give its composition as $C_{12}H_{18}O_4$.

Allied Barks.—MALAMBO-BARK is obtained in Venezuela from *Croton Malambo*, Karsten. It is in quills $\frac{1}{2}$ to 1 inch (12 to 25 Mm.) in diameter and 6 to 8 inches (15 to 20 Cm.) long. It has a thin, soft, whitish, longitudinally-fissured cork, which is easily removed, exhibiting a brown surface with fine transverse furrows; the inner surface is gray-brown, finely striate, the fracture short-splintery, the odor aromatic, and the taste unpleasantly aromatic and bitter, resembling that of cascarilla.

COPALCHI-BARK is obtained from *Croton Pseudochina*, Schlechtendal (*C. niveus*, Jacquin), indigenous to Mexico. It resembles the preceding, is about $\frac{1}{2}$ inch (5 Mm.) thick, hard and dense, has a grayish or yellowish corky layer, and beneath this is transversely fissured; the bast is reddish-brown, is coarsely striate in a radial direction, and breaks with a short, irregular fracture.

Barks differing considerably from those described, which are occasionally found in commerce as malambo- and copalchi-bark, are obtained from different plants. The composition of both barks is probably similar to that of cascarilla. Holmes (1874) described a bark which was probably derived from *Croton lucidus*, Linné, and was found as an admixture in cascarilla; it had a fawn-colored, firmly-adhering corky layer, was reddish and closely ridged upon the inner surface, had an astringent, slightly bitter taste, and yields a darker-colored tincture and infusion than cascarilla.

Pharmaceutical Preparations.—EXTRACTUM CASCARILLÆ, P. G. The coarsely-powdered bark is exhausted by digestion with hot water and the infusion evaporated. When prescribed in mixtures, Mylius recommends the extract to be dissolved in a little hot alcohol and the solution to be added to the watery liquid, whereby the cascarillin becomes finely divided and remains in suspension.

Off. Prep.—Infusum cascarillæ, U. S., Br.; Tinctura cascarillæ, Br.

Medical Action and Uses.—Cascarilla is stimulant rather than tonic, and its fumes when inhaled are intoxicating. The infusion occasions a sense of warmth in the stomach, but in excessive doses nauseates and purges. Cascarilla was originally used to enhance the febrifuge power of cinchona, and independently in the typhoid state of various diseases, especially epidemic dysentery. It is now chiefly employed in the treatment of dyspeptic conditions due to gastric or intestinal atony and attended with flatulence or vomiting. The dose in powder is about 30 grains (Gm. 2). The infusion, made with an ounce of cascarilla to a pint of water, is preferable. It may be given in wine-glassful doses.

Malambo-bark, says Strumpf, resembles Winter's bark in its action. In its native country it is used in atonic dyspepsia and in dysentery. The natives of Brazil have a superstition that the tapir cures itself of diarrhœa by eating this bark. It is also used by these people in asthma, spasms, and rheumatism, intermittent and yellow fevers, trismus nascentium, and worms. *Copalchi-bark*, according to the same authority, is employed as an antiperiodic-fever remedy, and tends to confine the bowels as well as to oppress the stomach. It is said to partake of the qualities of quassia, valerian, and menyanthis.

CASSIA FISTULA, U. S.—PURGING CASSIA.

Fructus cassiæ fistulæ.—*Casse officinale*, *Casse en batons*, Fr.; *Purgiercassie*, *Fistelkassie*, *Röhrencassie*, G.

The fruit of *Cassia Fistula*, Linné, s. *Cathartocarpus* (*Bactrylobium*, Willdenow) *Fistula*, Persoon. Woodv. t. 260; Bentley and Trimen, *Med. Plants*, 87.

Nat. Ord.—Leguminosæ, Cæsalpineæ.

Origin.—A tree 30 to 50 feet (9 to 15 M.) high, with large pinnate leaves appearing simultaneously with the long pendulous racemes of fragrant, golden-yellow, dark-veined flowers. Indigenous to the East Indies, it is now met with, spontaneous and under cultivation, in Egypt and other parts of Africa, the West Indies, and Brazil.

Description.—The fruit is an indehiscent, nearly cylindrical, woody legume, $1\frac{1}{2}$ to 2 feet (45 to 60 Cm.) long and nearly an inch (25 Mm.) thick, blackish-brown, with fine transverse veins and two bands running from the short thick stalk to the blunt apex. These bands are $\frac{1}{8}$ to $\frac{1}{4}$ inch (3 to 4 Mm.) broad, somewhat paler in color, smooth, and correspond to the dorsal and ventral sutures, the former being marked by a fine ridge, the latter by a shallow groove in the centre of the bands. The seeds are numerous, $\frac{1}{8}$ to $\frac{2}{5}$ inch (8 to 10 Mm.) long, flattish, ovate or oval, orange-brown, glossy, with a long filiform funiculus, a firm albumen, and fleshy-veined cotyledons; each seed is imbedded in a blackish-brown sweet pulp, and separately enclosed in a cell, the thin woody dissepiments being formed by the transverse distension of the placenta after fructification. Theodor suggests that of prunes.

FIG. 57.

Cassia fistula: part of pod, natural size.

Other Varieties.—A lighter-colored purging cassia is occasionally met with, which is from 12 to 18 or 20 inches (30 to 45 or 50 Cm.) long, about $\frac{1}{2}$ inch (12 Mm.) in diameter, slightly pointed, and has a reddish-brown sweet and somewhat astringent pulp, but otherwise resembles the officinal drug. It is usually referred to *Cassia bacillaris*, *Linné filius* (*Cathartocarpus bacillus*, *Persoon*), a tree indigenous to Surinam: but Hanbury's investigations (1863) render it certain that it is partly if not wholly obtained from *Cassia moschata*, *Kunth* (*Cathartocarpus moschatus*, *Don*), a tree found in Panama and the northern part of South America.

CASSIA BRASILIANA, *Lamarck* (*C. mollis*, *Vahl*, *C. grandis*, *Linné filius*, *Cathartocarpus*, *Persoon*), yields a large purging cassia, sometimes known as *horse cassia*, which is 2 feet (60 Cm.) and more long, often curved, laterally compressed, $1\frac{1}{2}$ inches (38 Mm.) broad, rather coarsely veined, and has the dorsal suture indicated by one convex band and the ventral suture by two prominent obtuse ridges.

Constituents.—Purging cassia, treated with water, should yield about 30 per cent. of pulp, which, according to the analyses by Vauquelin and Henry, consists principally of sugar (about 60 per cent.), with some mucilage, pectin, salts, etc. In view of this composition it is difficult to understand why the drug should be unfit for medicinal use when the pulp has become dry and the seeds remain loose in their cells; it would seem, however, to be not indispensable.

Pharmaceutical Preparations.—**CASSIÆ PULPA**, *Br.*—Cassia-pulp, *E.*; *Pulpe de casse*, *Casse mondé*, *Fr.*; *Cassienmus*, *G.*—It is extracted from the fruit by diffusing the pulp in water, straining, and evaporating. Cassia-pulp of British commerce, which has been imported from the East Indies, usually contains the seeds and dissepiments, and requires to be purified by softening with water and straining. It is blackish-brown, viscid, sweet, and of a somewhat sickly odor.
